Figure 17-27 shows how the Cache Capacity Bitmasks and the per-logical-processor Class of Service are logically used to enable Cache Allocation Technology. All (and only) contiguous 1's in the CBM are permitted. The length of CBM may vary from resource to resource or between processor generations and can be enumerated using CPUID. From the available mask set and based on the goals of the OS/VMM (shared or isolated cache, etc.) bitmasks are selected and associated with different classes of service. For the available Classes of Service the associated CBMs can be programmed via the global set of CAT configuration registers (in the case of L3 CAT, via the IA32_L3_MASK_n MSRs, where "n" is the Class of Service, starting from zero). In all architectural implementations supporting CPUID it is possible to change the CBMs dynamically, during program execution, unless stated otherwise by Intel.

The currently running application's Class of Service is communicated to the hardware through the per-logical-processor PQR MSR (IA32_PQR_ASSOC MSR). When the OS schedules an application thread on a logical processor, the application thread is associated with a specific COS (i.e. the corresponding COS in the PQR) and all requests to the CAT-capable resource from that logical processor are tagged with that COS (in other words, the application thread is configured to belong to a specific COS). The cache subsystem uses this tagged request information to enforce QoS. The capacity bitmask may be mapped into a way bitmask (or a similar enforcement entity based on the implementation) at the cache before it is applied to the allocation policy. For example, the capacity bitmask can be an 8-bit mask and the enforcement may be accomplished using a 16-way bitmask for a cache enforcement implementation based on way partitioning.

## 17.15.2 Enabling Cache Allocation Technology Usage Flow

Figure 17-28 illustrates the key steps for OS/VMM to detect support of Cache Allocation Technology and enable priority-based resource allocation for a CAT-capable resource.

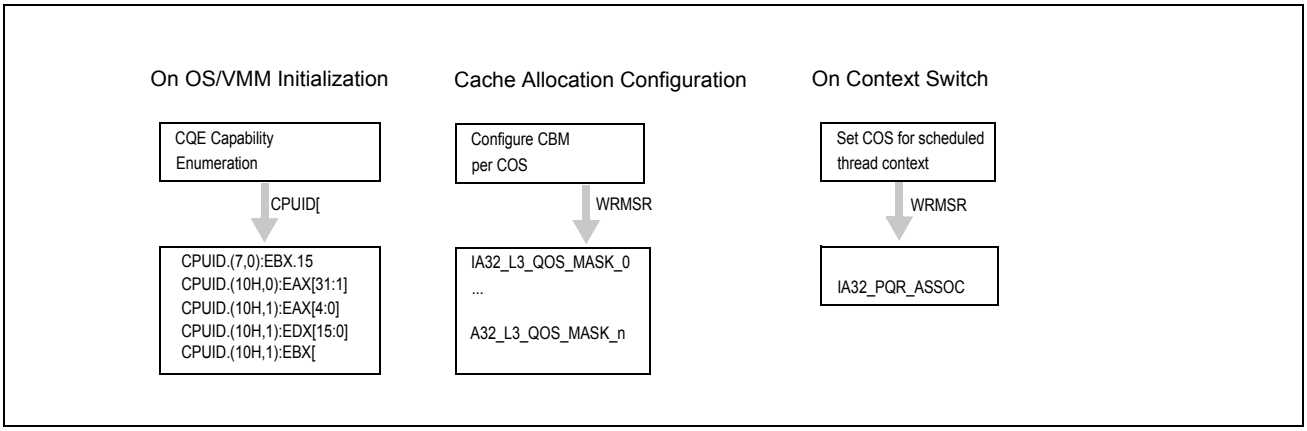

**Figure 17-28. Cache Allocation Technology Usage Flow**

### 17.15.2.1 Enumeration and Detection Support of Cache Allocation Technology

Availability of Cache Allocation Technology can be detected by calling CPUID leaf 7 and sub leaf 0 (Set EAX=07H, Set ECX=00H, call CPUID). This function is used to enumerate the extended feature flags supported by the processor. It loads feature flags in EAX, ECX, EBX and EDX registers. Bit position 15 in the EBX (EBX[15]) register indicates support for shared resource allocation control in general on the platform. If the value of this bit is set to 1 then it implies that the processor supports control over shared platform resources.

Software can query processor support of CAT capabilities by executing CPUID instruction with EAX = 07H, ECX = 0H as input. If CPUID.(EAX=07H, ECX=0):EBX.PQE[bit 15] reports 1, the processor supports Cache Allocation. Software must use CPUID leaf 10H to enumerate additional details of available resource types, classes of services and capability bitmasks. The programming interfaces provided by Cache Allocation Technology include:

- CPUID leaf function 10H (Cache Allocation Technology Enumeration leaf) and its sub-functions provide information on available resource types, and CAT capability for each resource type (see Section 17.15.2.2).
- IA32_L3_MASK_n: A range of MSRs is provided for each resource type, each MSR within that range specifying a software-configured capacity bitmask for each class of service. For L3 with Cache Allocation support, the CBM is specified using one of the IA32_L3_QOS_MASK_n MSR, where 'n' corresponds to a number within the supported range of COS, i.e. the range between 0 and CPUID.(EAX=10FH, ECX=ResID):EDX[15:0], inclusive. See Section 17.15.2.3 for details.
- IA32_PQR_ASSOC.CLOS: The IA32_PQR_ASSOC MSR provides a COS field that OS/VMM can use to assign a logical processor to an available COS. See Section 17.15.2.4 for details.

### 17.15.2.2 Cache Allocation Technology: Resource Type and Capability Enumeration

CPUID leaf function 10H (Cache Allocation Technology Enumeration leaf) provides two or more sub-functions:

- CAT Enumeration leaf sub-function 0 enumerates available resource types that support allocation control, i.e. by executing CPUID with EAX=10H and ECX=0H. In the initial implementation, L3 CAT is the only resource type available. Each supported resource type is represented by a bit field in CPUID.(EAX=10H, ECX=0):EBX[31:1]. The bit position of each set bit corresponds to a Resource ID (ResID). The ResID is also the sub-leaf index that software must use to query details of the CAT capability of that resource type (see Figure 17-29).

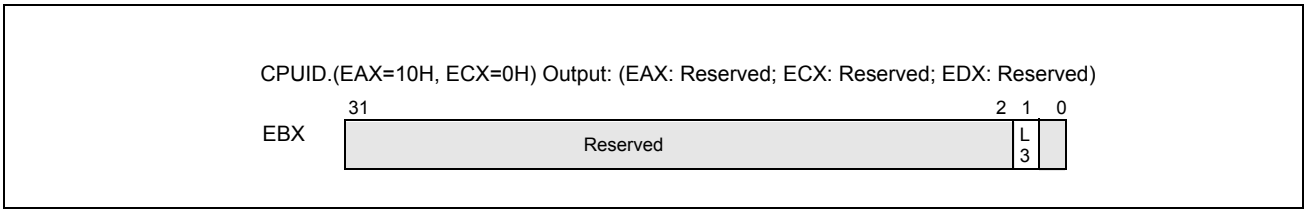

**Figure 17-29. CPUID.(EAX=10H, ECX=0H) Available Resource Type Identification**

- Sub-functions of CPUID.EAX=10H with a non-zero ECX input matching a supported ResID enumerate the specific enforcement details of the corresponding ResID. The capabilities enumerated include the length of the capacity bitmasks and the number of Classes of Service for a given ResID. Software must query the capability of each available ResID that supports CAT from a sub-leaf of leaf 10H using the sub-leaf index reported by the corresponding non-zero bit in CPUID.(EAX=10H, ECX=0):EBX[31:1]. CAT capability for L3 is enumerated by CPUID.(EAX=10H, ECX=1H), see Figure 17-30. The specific CAT capabilities reported by CPUID.(EAX=10H, ECX=1) are:

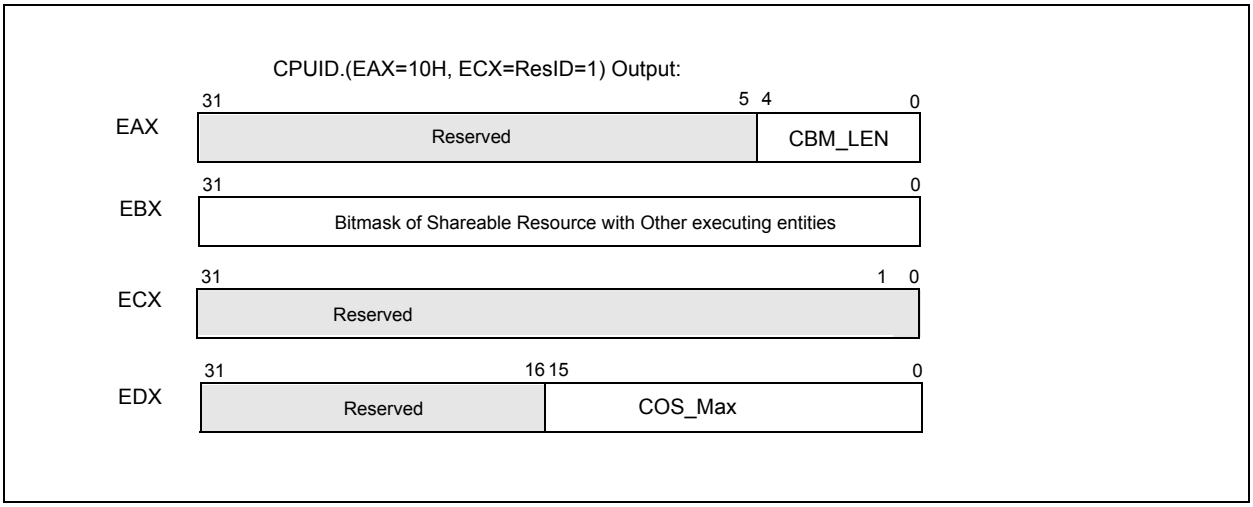

**Figure 17-30. L3 Cache Allocation Technology Enumeration (CPUID.(EAX=10H, ECX=1H) )**

  - CPUID.(EAX=10H, ECX=ResID=1):EAX[4:0] reports the length of the capacity bitmask length using minus-one notation, i.e. a value of 15 corresponds to the capability bitmask having length of 16 bits. Bits 31:5 of EAX are reserved.
  - CPUID.(EAX=10H, ECX=1):EBX[31:0] reports a bit mask. Each set bit within the length of the CBM indicates the corresponding unit of the L3 allocation may be used by other entities in the platform (e.g. an integrated graphics engine or hardware units outside the processor core and have direct access to L3). Each cleared bit within the length of the CBM indicates the corresponding allocation unit can be configured to implement a priority-based allocation scheme chosen by an OS/VMM without interference with other hardware agents in the system. Bits outside the length of the CBM are reserved.
  - CPUID.(EAX=10H, ECX=1):ECX: Reserved.
  - CPUID.(EAX=10H, ECX=1):EDX[15:0] reports the maximum COS supported for the resource (COS are zero-referenced, meaning a reported value of '15' would indicate 16 total supported COS). Bits 31:16 are reserved.

A note on migration of Classes of Service (COS): Software should minimize migrations of COS across logical processors (across threads or cores), as a reduction in the performance of the Cache Allocation Technology feature may result if COS are migrated frequently. This is aligned with the industry-standard practice of minimizing unnecessary thread migrations across processor cores in order to avoid excessive time spent warming up processor caches after a migration. In general, for best performance, minimize thread migration and COS migration across processor logical threads and processor cores.

### 17.15.2.3 Cache Mask Configuration

After determining the length of the capacity bitmasks (CBM) and number of COS supported using CPUID (see Section 17.15.2.2), each COS needs to be programmed with a CBM to dictate its available cache via a write to the corresponding IA32_resourceType_MASK_n register, where 'n' corresponds to a number within the supported range of COS, i.e. the range between 0 and CPUID.(EAX=10FH, ECX=ResID):EDX[15:0], inclusive, and 'resourceType' corresponds to a specific resource as enumerated by the set bits of CPUID.(EAX=10H, ECX=0):EAX[31:1].

A range of MSRs is reserved for Cache Allocation Technology registers of the form IA32_resourceType_MASK_n, from 0C90H through 0D8FH (inclusive), providing support for up to 256 Classes of Service or multiple resource types. In the first implementation the only supported resourceType is 'L3', corresponding to the L3 cache in a platform. All CAT configuration registers can be accessed using the standard RDMSR / WRMSR instructions.

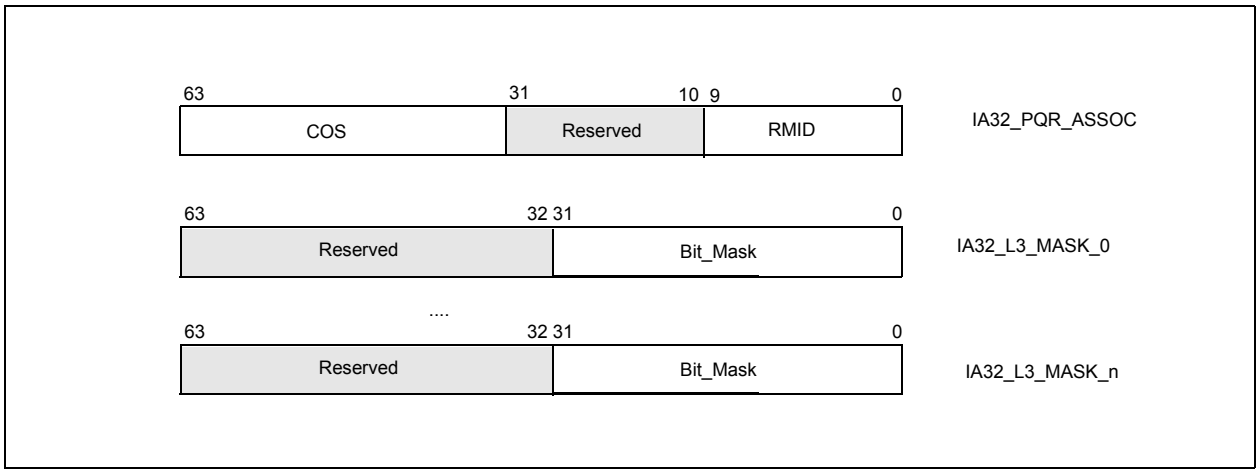

**Figure 17-31. IA32_PQR_ASSOC, IA32_L3_MASK_n MSRs**

### 17.15.2.4 Cache Mask Association

After configuring the available classes of service with the preferred set of capacity bitmasks, the OS/VMM can set the IA32_PQR_ASSOC.COS of a logical processor to the class of service with the desired CBM when a thread context switch occurs. This allows the OS/VMM to indicate which class of service an executing thread/VM belongs to. Each logical processor contains an instance of the IA32_PQR_ASSOC register at MSR location 0C8FH, and Figure 17-31 shows the bit field layout for this register. Bits[63:32] contain the COS field for each logical processor.

Specifying a COS value in IA32_PQR_ASSOC.COS greater than the value reported by CPUID.(EAX=10FH, ECX=ResID):EDX[15:0] will cause a #GP(0). The value of IA32_PQR_ASSOC.COS after power-on is 0.

Note that if the IA32_PQR_ASSOC.COS is never written then the CAT capability defaults to using COS 0, which in turn is set to the default mask in IA32_L3_MASK_0 - which is all "1"s (on reset). This essentially disables the enforcement feature by default or for legacy operating systems and software.

## 17.15.3 Cache Allocation Technology Programming Considerations

### 17.15.3.1 Cache Allocation Technology Dynamic Configuration

Both the CQE masks and PQR registers are accessible and modifiable at any time during execution using RDMSR/WRMSR unless otherwise noted. When writing to these MSRs a #GP(0) will be generated if any of the following conditions occur:

- A reserved bit is modified,
- Accessing a QOS mask register outside the supported COS (the max COS number is specified in CPUID.(EAX=10FH, ECX=ResID):EDX[15:0]), or
- Writing a COS greater than the supported maximum (specified as the maximum value of CPUID.(EAX=10FH, ECX=ResID):EDX[15:0] for all valid ResID values) is written to the IA32_PQR_ASSOC.CLOS field.

When reading the IA32_PQR_ASSOC register the currently programmed COS on the core will be returned.

When reading an IA32_*resourceType*_MASK_*n* register the current capacity bit mask for COS 'n' will be returned.

As noted previously, software should minimize migrations of COS across logical processors (across threads or cores), as a reduction in the accuracy of the Cache Allocation feature may result if COS are migrated frequently. This is aligned with the industry standard practice of minimizing unnecessary thread migrations across processor

cores in order to avoid excessive time spent warming up processor caches after a migration. In general, for best performance, minimize thread migration and COS migration across processor logical threads and processor cores.

### 17.15.3.2 Cache Allocation Technology Operation With Power Saving Features

Note that the Cache Allocation Technology feature cannot be used to enforce cache coherency, and that some advanced power management features such as C-states which may shrink or power off various caches within the system may interfere with CAT hints - in such cases the CAT bitmasks are ignored and the other features take precedence. If the highest possible level of CAT differentiation or determinism is required, disable any power-saving features which shrink the caches or power off caches. The details of the power management interfaces are typically implementation-specific, but can be found at *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3C*.

If software requires differentiation between threads but not absolute determinism then in many cases it is possible to leave power-saving cache shrink features enabled, which can provide substantial power savings and increase battery life in mobile platforms. In such cases when the caches are powered off (e.g., package C-states) the entire cache of a portion thereof may be powered off. Upon resuming an active state any new incoming data to the cache will be filled subject to the cache capacity bitmasks. Any data in the cache prior to the cache shrink or power off may have been flushed to memory during the process of entering the idle state, however, and is not guaranteed to remain in the cache. If differentiation between threads is the goal of system software then this model allows substantial power savings while continuing to deliver performance differentiation. If system software needs optimal determinism then power saving modes which flush portions of the caches and power them off should be disabled.

**NOTE**

IA32_PQR_ASSOC is saved and restored across C6 entry/exit. Similarly, the mask register contents are saved across package C-state entry/exit and are not lost.

### 17.15.3.3 Cache Allocation Technology Operation with Other Operating Modes

The states in IA32_PQR_ASSOC and mask registers are unmodified across an SMI delivery. Thus, the execution of SMM handler code can interact with the Cache Allocation Technology resource and manifest some degree of non-determinism to the non-SMM software stack. An SMM handler may also perform certain system-level or power management practices that affect CAT operation.

It is possible for an SMM handler to minimize the impact on data determinism in the cache by reserving a COS with a dedicated partition in the cache. Such an SMM handler can switch to the dedicated COS immediately upon entering SMM, and switching back to the previously running COS upon exit.

# CHAPTER 18
# PERFORMANCE MONITORING

Intel 64 and IA-32 architectures provide facilities for monitoring performance.

## 18.1 PERFORMANCE MONITORING OVERVIEW

Performance monitoring was introduced in the Pentium processor with a set of model-specific performance-monitoring counter MSRs. These counters permit selection of processor performance parameters to be monitored and measured. The information obtained from these counters can be used for tuning system and compiler performance.

In Intel P6 family of processors, the performance monitoring mechanism was enhanced to permit a wider selection of events to be monitored and to allow greater control events to be monitored. Next, Pentium 4 and Intel Xeon processors introduced a new performance monitoring mechanism and new set of performance events.

The performance monitoring mechanisms and performance events defined for the Pentium, P6 family, Pentium 4, and Intel Xeon processors are not architectural. They are all model specific (not compatible among processor families). Intel Core Solo and Intel Core Duo processors support a set of architectural performance events and a set of non-architectural performance events. Processors based on Intel Core microarchitecture and Intel® Atom™ microarchitecture support enhanced architectural performance events and non-architectural performance events.

Starting with Intel Core Solo and Intel Core Duo processors, there are two classes of performance monitoring capabilities. The first class supports events for monitoring performance using counting or sampling usage. These events are non-architectural and vary from one processor model to another. They are similar to those available in Pentium M processors. These non-architectural performance monitoring events are specific to the microarchitecture and may change with enhancements. They are discussed in Section 18.3, "Performance Monitoring (Intel® Core™ Solo and Intel® Core™ Duo Processors)." Non-architectural events for a given microarchitecture can not be enumerated using CPUID; and they are listed in Chapter 19, "Performance-Monitoring Events."

The second class of performance monitoring capabilities is referred to as architectural performance monitoring. This class supports the same counting and sampling usages, with a smaller set of available events. The visible behavior of architectural performance events is consistent across processor implementations. Availability of architectural performance monitoring capabilities is enumerated using the CPUID.0AH. These events are discussed in Section 18.2.

## 18.2 ARCHITECTURAL PERFORMANCE MONITORING

Performance monitoring events are architectural when they behave consistently across microarchitectures. Intel Core Solo and Intel Core Duo processors introduced architectural performance monitoring. The feature provides a mechanism for software to enumerate performance events and provides configuration and counting facilities for events.

Architectural performance monitoring does allow for enhancement across processor implementations. The CPUID.0AH leaf provides version ID for each enhancement. Intel Core Solo and Intel Core Duo processors support base level functionality identified by version ID of 1. Processors based on Intel Core microarchitecture support, at a minimum, the base level functionality of architectural performance monitoring. Intel Core 2 Duo processor T 7700 and newer processors based on Intel Core microarchitecture support both the base level functionality and enhanced architectural performance monitoring identified by version ID of 2.

Intel Atom processor family supports the base level functionality, enhanced architectural performance monitoring identified by version ID of 2 and version ID of 3 (including two general-purpose performance counters, IA32_PMC0, IA32_PMC1). Intel Core i7 processor family supports the base level functionality, enhanced architectural performance monitoring identified by version ID of 2 and version ID of 3, (including four general-purpose performance counters, IA32_PMC0-IA32_PMC3).

### 18.2.1 Architectural Performance Monitoring Version 1

Configuring an architectural performance monitoring event involves programming performance event select registers. There are a finite number of performance event select MSRs (IA32_PERFEVTSELx MSRs). The result of a performance monitoring event is reported in a performance monitoring counter (IA32_PMCx MSR). Performance monitoring counters are paired with performance monitoring select registers.

Performance monitoring select registers and counters are architectural in the following respects:

- Bit field layout of IA32_PERFEVTSELx is consistent across microarchitectures.
- Addresses of IA32_PERFEVTSELx MSRs remain the same across microarchitectures.
- Addresses of IA32_PMC MSRs remain the same across microarchitectures.
- Each logical processor has its own set of IA32_PERFEVTSELx and IA32_PMCx MSRs. Configuration facilities and counters are not shared between logical processors sharing a processor core.

Architectural performance monitoring provides a CPUID mechanism for enumerating the following information:

- Number of performance monitoring counters available in a logical processor (each IA32_PERFEVTSELx MSR is paired to the corresponding IA32_PMCx MSR)
- Number of bits supported in each IA32_PMCx
- Number of architectural performance monitoring events supported in a logical processor

Software can use CPUID to discover architectural performance monitoring availability (CPUID.0AH). The architectural performance monitoring leaf provides an identifier corresponding to the version number of architectural performance monitoring available in the processor.

The version identifier is retrieved by querying CPUID.0AH:EAX[bits 7:0] (see Chapter 3, "Instruction Set Reference, A-M," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*). If the version identifier is greater than zero, architectural performance monitoring capability is supported. Software queries the

CPUID.0AH for the version identifier first; it then analyzes the value returned in CPUID.0AH.EAX, CPUID.0AH.EBX to determine the facilities available.

In the initial implementation of architectural performance monitoring; software can determine how many IA32_PERFEVTSELx/ IA32_PMCx MSR pairs are supported per core, the bit-width of PMC, and the number of architectural performance monitoring events available.

### 18.2.1.1 Architectural Performance Monitoring Version 1 Facilities

Architectural performance monitoring facilities include a set of performance monitoring counters and performance event select registers. These MSRs have the following properties:

- IA32_PMCx MSRs start at address 0C1H and occupy a contiguous block of MSR address space; the number of MSRs per logical processor is reported using CPUID.0AH:EAX[15:8].
- IA32_PERFEVTSELx MSRs start at address 186H and occupy a contiguous block of MSR address space. Each performance event select register is paired with a corresponding performance counter in the 0C1H address block.
- The bit width of an IA32_PMCx MSR is reported using the CPUID.0AH:EAX[23:16]. This the number of valid bits for read operation. On write operations, the lower-order 32 bits of the MSR may be written with any value, and the high-order bits are sign-extended from the value of bit 31.
- Bit field layout of IA32_PERFEVTSELx MSRs is defined architecturally.

See Figure 18-1 for the bit field layout of IA32_PERFEVTSELx MSRs. The bit fields are:

- **Event select field (bits 0 through 7) —** Selects the event logic unit used to detect microarchitectural conditions (see Table 18-1, for a list of architectural events and their 8-bit codes). The set of values for this field is defined architecturally; each value corresponds to an event logic unit for use with an architectural performance event. The number of architectural events is queried using CPUID.0AH:EAX. A processor may support only a subset of pre-defined values.

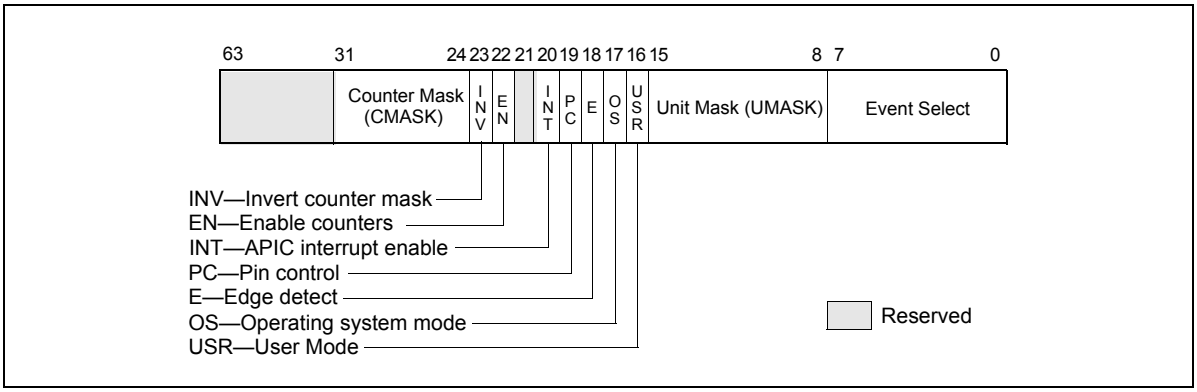

Figure 18-1. Layout of IA32_PERFEVTSELx MSRs

- **Unit mask (UMASK) field (bits 8 through 15)** — These bits qualify the condition that the selected event logic unit detects. Valid UMASK values for each event logic unit are specific to the unit. For each architectural performance event, its corresponding UMASK value defines a specific microarchitectural condition.

  A pre-defined microarchitectural condition associated with an architectural event may not be applicable to a given processor. The processor then reports only a subset of pre-defined architectural events. Pre-defined architectural events are listed in Table 18-1; support for pre-defined architectural events is enumerated using CPUID.0AH:EBX. Architectural performance events available in the initial implementation are listed in Table 19-1.
- **USR (user mode) flag (bit 16) —** Specifies that the selected microarchitectural condition is counted only when the logical processor is operating at privilege levels 1, 2 or 3. This flag can be used with the OS flag.

- **OS (operating system mode) flag (bit 17) —** Specifies that the selected microarchitectural condition is counted only when the logical processor is operating at privilege level 0. This flag can be used with the USR flag.
- **E (edge detect) flag (bit 18) —** Enables (when set) edge detection of the selected microarchitectural condition. The logical processor counts the number of deasserted to asserted transitions for any condition that can be expressed by the other fields. The mechanism does not permit back-to-back assertions to be distinguished.

  This mechanism allows software to measure not only the fraction of time spent in a particular state, but also the average length of time spent in such a state (for example, the time spent waiting for an interrupt to be serviced).
- **PC (pin control) flag (bit 19) —** When set, the logical processor toggles the PM*i* pins and increments the counter when performance-monitoring events occur; when clear, the processor toggles the PM*i* pins when the counter overflows. The toggling of a pin is defined as assertion of the pin for a single bus clock followed by deassertion.
- **INT (APIC interrupt enable) flag (bit 20) —** When set, the logical processor generates an exception through its local APIC on counter overflow.
- **EN (Enable Counters) Flag (bit 22) —** When set, performance counting is enabled in the corresponding performance-monitoring counter; when clear, the corresponding counter is disabled. The event logic unit for a UMASK must be disabled by setting IA32_PERFEVTSELx[bit 22] = 0, before writing to IA32_PMCx.
- **INV (invert) flag (bit 23) —** When set, inverts the counter-mask (CMASK) comparison, so that both greater than or equal to and less than comparisons can be made (0: greater than or equal; 1: less than). Note if counter-mask is programmed to zero, INV flag is ignored.
- **Counter mask (CMASK) field (bits 24 through 31) —** When this field is not zero, a logical processor compares this mask to the events count of the detected microarchitectural condition during a single cycle. If the event count is greater than or equal to this mask, the counter is incremented by one. Otherwise the counter is not incremented.

  This mask is intended for software to characterize microarchitectural conditions that can count multiple occurrences per cycle (for example, two or more instructions retired per clock; or bus queue occupations). If the counter-mask field is 0, then the counter is incremented each cycle by the event count associated with multiple occurrences.

### 18.2.2 Additional Architectural Performance Monitoring Extensions

The enhanced features provided by architectural performance monitoring version 2 include the following:

- **Fixed-function performance counter register and associated control register** — Three of the architectural performance events are counted using three fixed-function MSRs (IA32_FIXED_CTR0 through IA32_FIXED_CTR2). Each of the fixed-function PMC can count only one architectural performance event.

  Configuring the fixed-function PMCs is done by writing to bit fields in the MSR (IA32_FIXED_CTR_CTRL) located at address 38DH. Unlike configuring performance events for general-purpose PMCs (IA32_PMCx) via UMASK field in (IA32_PERFEVTSELx), configuring, programming IA32_FIXED_CTR_CTRL for fixed-function PMCs do not require any UMASK.
- **Simplified event programming** — Most frequent operation in programming performance events are enabling/disabling event counting and checking the status of counter overflows. Architectural performance event version 2 provides three architectural MSRs:
  - — IA32_PERF_GLOBAL_CTRL allows software to enable/disable event counting of all or any combination of fixed-function PMCs (IA32_FIXED_CTRx) or any general-purpose PMCs via a single WRMSR.
  - — IA32_PERF_GLOBAL_STATUS allows software to query counter overflow conditions on any combination of fixed-function PMCs or general-purpose PMCs via a single RDMSR.
  - — IA32_PERF_GLOBAL_OVF_CTRL allows software to clear counter overflow conditions on any combination of fixed-function PMCs or general-purpose PMCs via a single WRMSR.

### 18.2.2.1 Architectural Performance Monitoring Version 2 Facilities

The facilities provided by architectural performance monitoring version 2 can be queried from CPUID leaf 0AH by examining the content of register EDX:

- Bits 0 through 4 of CPUID.0AH.EDX indicates the number of fixed-function performance counters available per core,
- Bits 5 through 12 of CPUID.0AH.EDX indicates the bit-width of fixed-function performance counters. Bits beyond the width of the fixed-function counter are reserved and must be written as zeros.

NOTE

Early generation of processors based on Intel Core microarchitecture may report in CPUID.0AH:EDX of support for version 2 but indicating incorrect information of version 2 facilities.

The IA32_FIXED_CTR_CTRL MSR include multiple sets of 4-bit field, each 4 bit field controls the operation of a fixed-function performance counter. Figure 18-2 shows the layout of 4-bit controls for each fixed-function PMC. Two sub-fields are currently defined within each control. The definitions of the bit fields are:

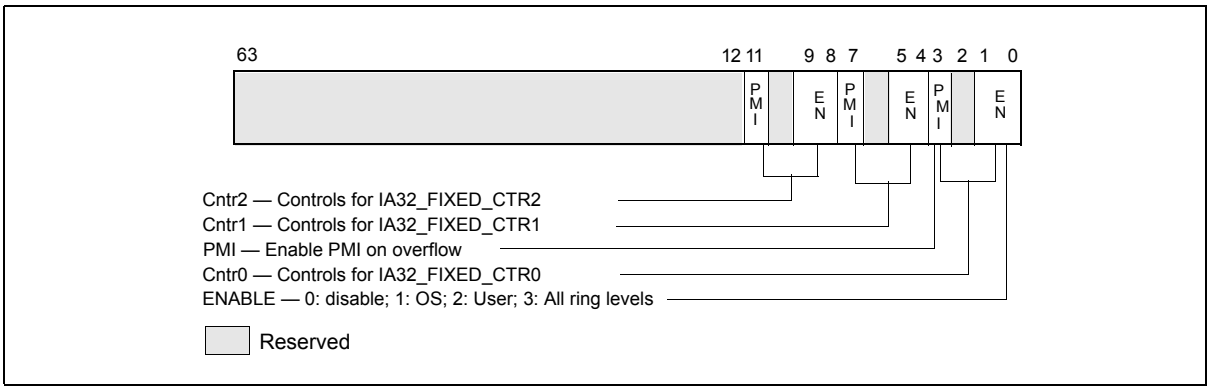

Figure 18-2. Layout of IA32_FIXED_CTR_CTRL MSR

- **Enable field (lowest 2 bits within each 4-bit control)** — When bit 0 is set, performance counting is enabled in the corresponding fixed-function performance counter to increment while the target condition associated with the architecture performance event occurred at ring 0. When bit 1 is set, performance counting is enabled in the corresponding fixed-function performance counter to increment while the target condition associated with the architecture performance event occurred at ring greater than 0. Writing 0 to both bits stops the performance counter. Writing a value of 11B enables the counter to increment irrespective of privilege levels.
- **PMI field (the fourth bit within each 4-bit control)** — When set, the logical processor generates an exception through its local APIC on overflow condition of the respective fixed-function counter.

IA32_PERF_GLOBAL_CTRL MSR provides single-bit controls to enable counting of each performance counter. Figure 18-3 shows the layout of IA32_PERF_GLOBAL_CTRL. Each enable bit in IA32_PERF_GLOBAL_CTRL is AND'ed with the enable bits for all privilege levels in the respective IA32_PERFEVTSELx or IA32_PERF_FIXED_CTR_CTRL MSRs to start/stop the counting of respective counters. Counting is enabled if the AND'ed results is true; counting is disabled when the result is false.

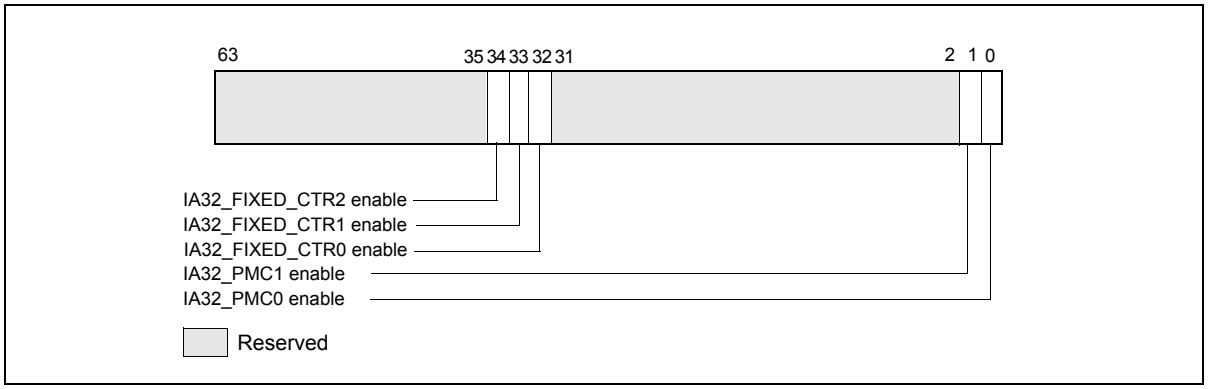

**Figure 18-3. Layout of IA32_PERF_GLOBAL_CTRL MSR**

The fixed-function performance counters supported by architectural performance version 2 is listed in Table 18-8, the pairing between each fixed-function performance counter to an architectural performance event is also shown.

IA32_PERF_GLOBAL_STATUS MSR provides single-bit status for software to query the overflow condition of each performance counter. The MSR also provides additional status bit to indicate overflow conditions when counters are programmed for precise-event-based sampling (PEBS). IA32_PERF_GLOBAL_STATUS MSR also provides a Cond-Chgd bit to indicate changes to the state of performance monitoring hardware. Figure 18-4 shows the layout of IA32_PERF_GLOBAL_STATUS. A value of 1 in bits 0, 1, 32 through 34 indicates a counter overflow condition has occurred in the associated counter.

When a performance counter is configured for PEBS, overflow condition in the counter generates a performance-monitoring interrupt signaling a PEBS event. On a PEBS event, the processor stores data records into the buffer area (see Section 18.15.5), clears the counter overflow status., and sets the "OvfBuffer" bit in IA32_PERF_GLOBAL_STATUS.

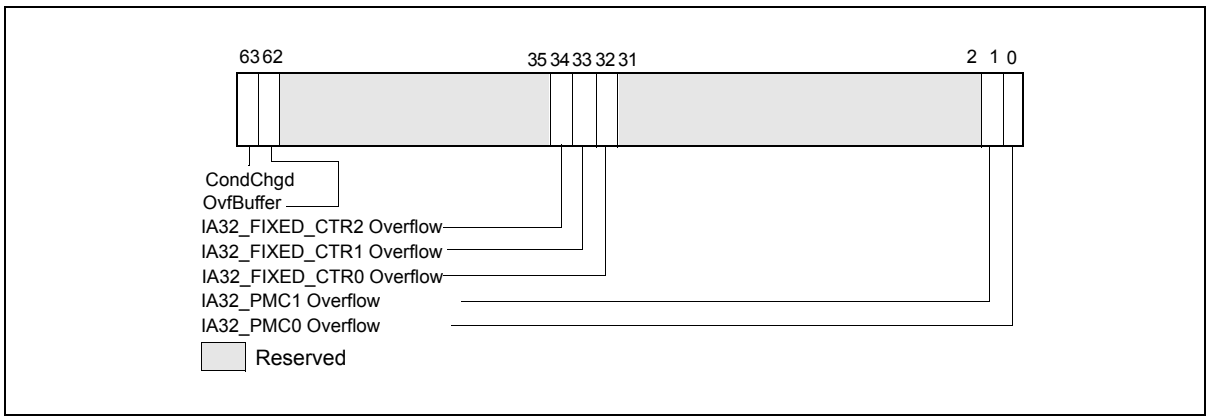

**Figure 18-4. Layout of IA32_PERF_GLOBAL_STATUS MSR**

IA32_PERF_GLOBAL_OVF_CTL MSR allows software to clear overflow indicator(s) of any general-purpose or fixed-function counters via a single WRMSR. Software should clear overflow indications when

- Setting up new values in the event select and/or UMASK field for counting or sampling
- Reloading counter values to continue sampling
- Disabling event counting or sampling.

The layout of IA32_PERF_GLOBAL_OVF_CTL is shown in Figure 18-5.

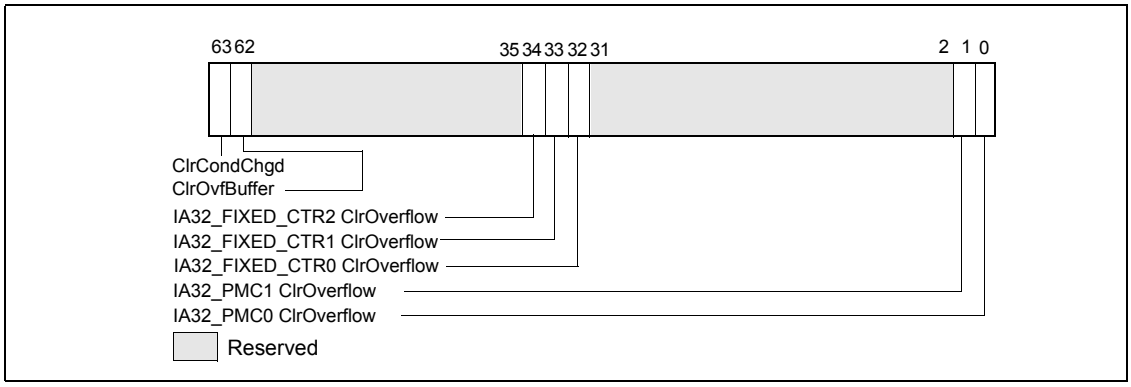

Figure 18-5. Layout of IA32_PERF_GLOBAL_OVF_CTRL MSR

### 18.2.2.2 Architectural Performance Monitoring Version 3 Facilities

The facilities provided by architectural performance monitoring version 1 and 2 are also supported by architectural performance monitoring version 3. Additionally version 3 provides enhancements to support a processor core comprising of more than one logical processor, i.e. a processor core supporting Intel Hyper-Threading Technology or simultaneous multi-threading capability. Specifically,

- CPUID leaf 0AH provides enumeration mechanisms to query:
  - The number of general-purpose performance counters (IA32_PMCx) is reported in CPUID.0AH:EAX[15:8], the bit width of general-purpose performance counters (see also Section 18.2.1.1) is reported in CPUID.0AH:EAX[23:16].
  - The bit vector representing the set of architectural performance monitoring events supported (see Section 18.2.3)
  - The number of fixed-function performance counters, the bit width of fixed-function performance counters (see also Section 18.2.2.1).
- Each general-purpose performance counter IA32_PMCx (starting at MSR address 0C1H) is associated with a corresponding IA32_PERFEVTSELx MSR (starting at MSR address 186H). The Bit field layout of IA32_PERFEVTSELx MSRs is defined architecturally in Figure 18-6.

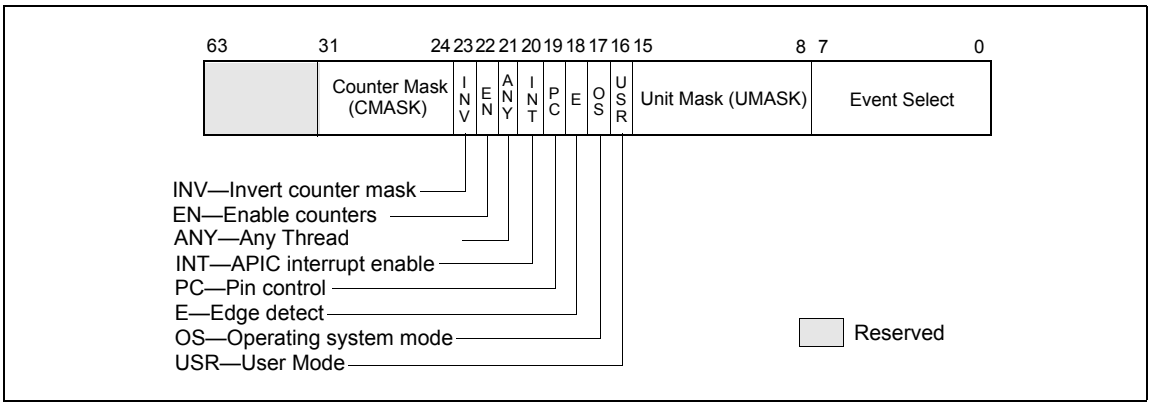

Figure 18-6. Layout of IA32_PERFEVTSELx MSRs Supporting Architectural Performance Monitoring Version 3

**Bit 21 (AnyThread)** of IA32_PERFEVTSELx is supported in architectural performance monitoring version 3. When set to 1, it enables counting the associated event conditions (including matching the thread's CPL with the OS/USR setting of IA32_PERFEVTSELx) occurring across all logical processors sharing a processor core. When bit 21 is 0, the counter only increments the associated event conditions (including matching the thread's CPL with the OS/USR setting of IA32_PERFEVTSELx) occurring in the logical processor which programmed the IA32_PERFEVTSELx MSR.

- Each fixed-function performance counter IA32_FIXED_CTRx (starting at MSR address 309H) is configured by a 4-bit control block in the IA32_PERF_FIXED_CTR_CTRL MSR. The control block also allow thread-specificity configuration using an AnyThread bit. The layout of IA32_PERF_FIXED_CTR_CTRL MSR is shown.

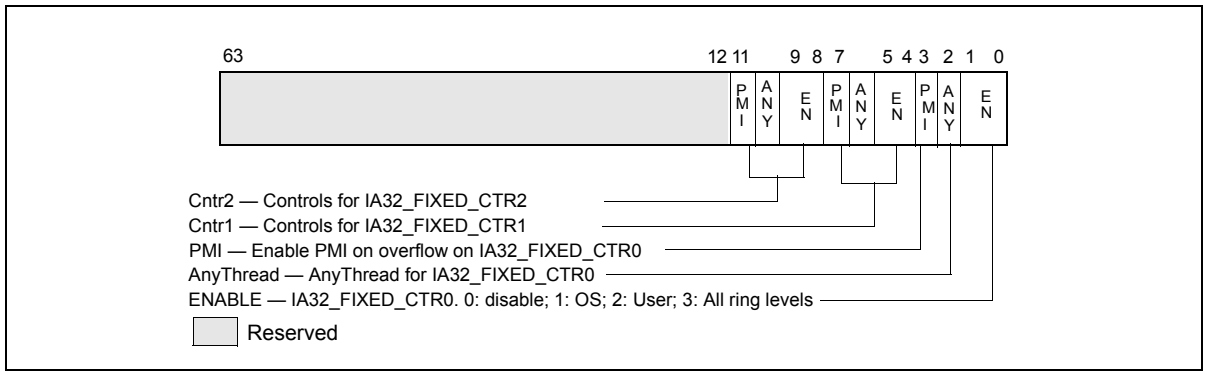

**Figure 18-7. Layout of IA32_FIXED_CTR_CTRL MSR Supporting Architectural Performance Monitoring Version 3**

Each control block for a fixed-function performance counter provides a **AnyThread** (bit position 2 + 4*N, N= 0, 1, etc.) bit. When set to 1, it enables counting the associated event conditions (including matching the thread's CPL with the ENABLE setting of the corresponding control block of IA32_PERF_FIXED_CTR_CTRL) occurring across all logical processors sharing a processor core. When an **AnyThread** bit is 0 in IA32_PERF_FIXED_CTR_CTRL, the corresponding fixed counter only increments the associated event conditions occurring in the logical processor which programmed the IA32_PERF_FIXED_CTR_CTRL MSR.

- The IA32_PERF_GLOBAL_CTRL, IA32_PERF_GLOBAL_STATUS, IA32_PERF_GLOBAL_OVF_CTRL MSRs provide single-bit controls/status for each general-purpose and fixed-function performance counter. Figure 18-8 and Figure 18-9 show the layout of these MSRs for N general-purpose performance counters (where N is reported by CPUID.0AH:EAX[15:8]) and three fixed-function counters.

  **Note:** The Intel Atom processor family supports two general-purpose performance monitoring counters (i.e. N =2 in Figure 18-9), other processor families in Intel 64 architecture may support a different value of N in Figure 18-9. The number N is reported by CPUID.0AH:EAX[15:8]. The Intel Core i7 processor supports four general-purpose performance monitoring counters (i.e. N =4 in Figure 18-9).

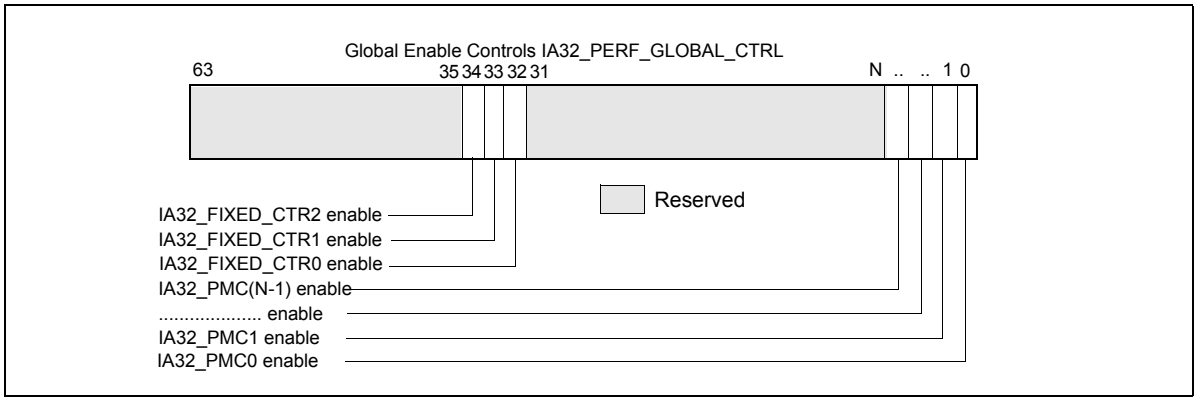

**Figure 18-8. Layout of Global Performance Monitoring Control MSR**

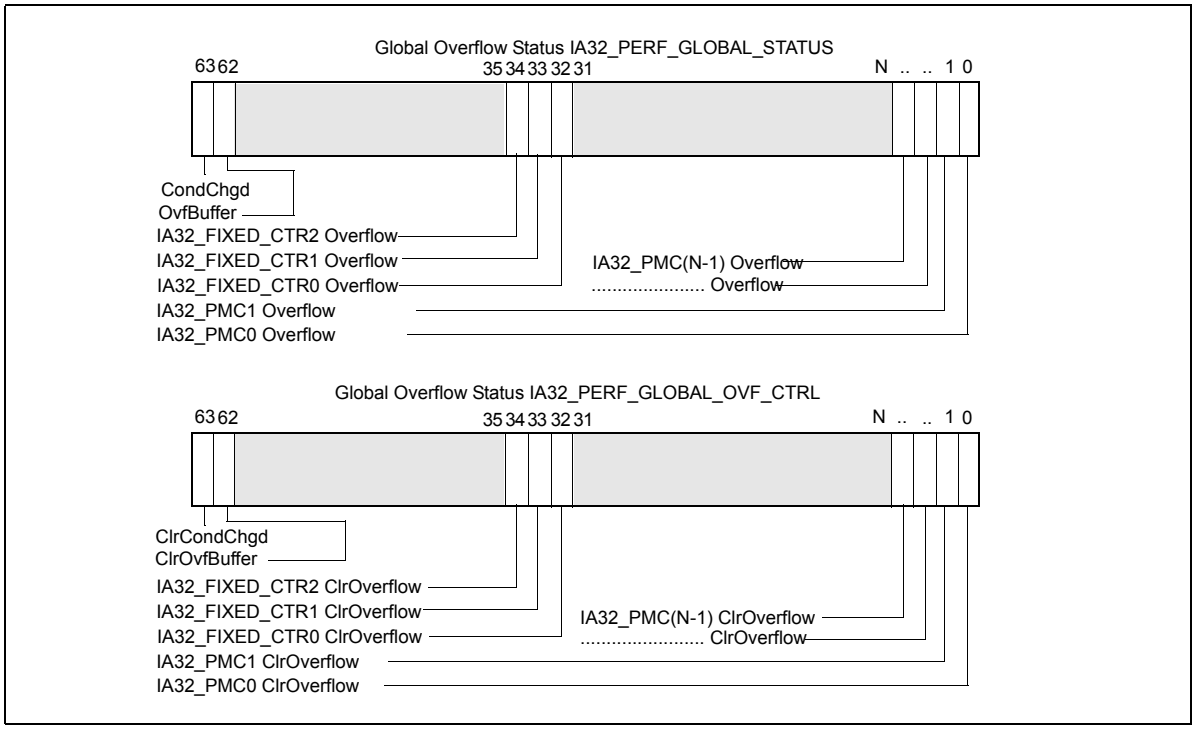

**Figure 18-9. Global Performance Monitoring Overflow Status and Control MSRs**

### 18.2.2.3 Full-Width Writes to Performance Counter Registers

The general-purpose performance counter registers IA32_PMCx are writable via WRMSR instruction. However, the value written into IA32_PMCx by WRMSR is the signed extended 64-bit value of the EAX[31:0] input of WRMSR.

A processor that supports full-width writes to the general-purpose performance counters enumerated by CPUID.0AH:EAX[15:8] will set IA32_PERF_CAPABILITIES[13] to enumerate its full-width-write capability See Figure 18-43.

If IA32_PERF_CAPABILITIES.FW_WRITE[bit 13] =1, each IA32_PMCi is accompanied by a corresponding alias address starting at 4C1H for IA32_A_PMC0.

If IA32_A_PMCi is present, the 64-bit input value (EDX:EAX) of WRMSR to IA32_A_PMCi will cause IA32_PMCi to be updated by:

IA32_PMCi[63:32] ← SignExtend(EDX[N-32:0]);

IA32_PMCi[31:0] ← EAX[31:0];

## 18.2.3 Pre-defined Architectural Performance Events

Table 18-1 lists architecturally defined events.

**Table 18-1. UMask and Event Select Encodings for Pre-Defined Architectural Performance Events**

| Bit Position CPUID.AH.EBX | Event Name | UMask | Event Select |
|---|---|---|---|
| 0 | UnHalted Core Cycles | 00H | 3CH |
| 1 | Instruction Retired | 00H | C0H |
| 2 | UnHalted Reference Cycles | 01H | 3CH |
| 3 | LLC Reference | 4FH | 2EH |

**Table 18-1. UMask and Event Select Encodings for Pre-Defined Architectural Performance Events**

| | | | |
|---|---|---|---|
| 4 | LLC Misses | 41H | 2EH |
| 5 | Branch Instruction Retired | 00H | C4H |
| 6 | Branch Misses Retired | 00H | C5H |

A processor that supports architectural performance monitoring may not support all the predefined architectural performance events (Table 18-1). The non-zero bits in CPUID.0AH:EBX indicate the events that are not available.

The behavior of each architectural performance event is expected to be consistent on all processors that support that event. Minor variations between microarchitectures are noted below:

- **UnHalted Core Cycles —** Event select 3CH, Umask 00H

  This event counts core clock cycles when the clock signal on a specific core is running (not halted). The counter does not advance in the following conditions:

  — an ACPI C-state other than C0 for normal operation

  — HLT

  — STPCLK# pin asserted

  — being throttled by TM1

  — during the frequency switching phase of a performance state transition (see Chapter 14, "Power and Thermal Management")

  The performance counter for this event counts across performance state transitions using different core clock frequencies

- **Instructions Retired —** Event select C0H, Umask 00H

  This event counts the number of instructions at retirement. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. An instruction with a REP prefix counts as one instruction (not per iteration). Faults before the retirement of the last micro-op of a multi-ops instruction are not counted.

  This event does not increment under VM-exit conditions. Counters continue counting during hardware interrupts, traps, and inside interrupt handlers.

- **UnHalted Reference Cycles —** Event select 3CH, Umask 01H

  This event counts reference clock cycles while the clock signal on the core is running. The reference clock operates at a fixed frequency, irrespective of core frequency changes due to performance state transitions. Processors may implement this behavior differently. See Table 19-19 and Table 19-22 in Chapter 19, "Performance-Monitoring Events."

- **Last Level Cache References —** Event select 2EH, Umask 4FH

  This event counts requests originating from the core that reference a cache line in the last level cache. The event count includes speculation and cache line fills due to the first-level cache hardware prefetcher, but may exclude cache line fills due to other hardware-prefetchers.

  Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended.

- **Last Level Cache Misses —** Event select 2EH, Umask 41H

  This event counts each cache miss condition for references to the last level cache. The event count may include speculation and cache line fills due to the first-level cache hardware prefetcher, but may exclude cache line fills due to other hardware-prefetchers.

  Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended.

- **Branch Instructions Retired —** Event select C4H, Umask 00H

  This event counts branch instructions at retirement. It counts the retirement of the last micro-op of a branch instruction.

- **All Branch Mispredict Retired —** Event select C5H, Umask 00H

This event counts mispredicted branch instructions at retirement. It counts the retirement of the last micro-op of a branch instruction in the architectural path of execution and experienced misprediction in the branch prediction hardware.

Branch prediction hardware is implementation-specific across microarchitectures; value comparison to estimate performance differences is not recommended.

**NOTE**

Programming decisions or software precisians on functionality should not be based on the event values or dependent on the existence of performance monitoring events.

## 18.3 PERFORMANCE MONITORING (INTEL® CORE™ SOLO AND INTEL® CORE™ DUO PROCESSORS)

In Intel Core Solo and Intel Core Duo processors, non-architectural performance monitoring events are programmed using the same facilities (see Figure 18-1) used for architectural performance events.

Non-architectural performance events use event select values that are model-specific. Event mask (Umask) values are also specific to event logic units. Some microarchitectural conditions detectable by a Umask value may have specificity related to processor topology (see Section 8.6, "Detecting Hardware Multi-Threading Support and Topology," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*). As a result, the unit mask field (for example, IA32_PERFEVTSELx[bits 15:8]) may contain sub-fields that specify topology information of processor cores.

The sub-field layout within the Umask field may support two-bit encoding that qualifies the relationship between a microarchitectural condition and the originating core. This data is shown in Table 18-2. The two-bit encoding for core-specificity is only supported for a subset of Umask values (see Chapter 19, "Performance Monitoring Events") and for Intel Core Duo processors. Such events are referred to as core-specific events.

**Table 18-2. Core Specificity Encoding within a Non-Architectural Umask**

| IA32_PERFEVTSELx MSRs | |
|---|---|
| **Bit 15:14 Encoding** | **Description** |
| 11B | All cores |
| 10B | Reserved |
| 01B | This core |
| 00B | Reserved |

Some microarchitectural conditions allow detection specificity only at the boundary of physical processors. Some bus events belong to this category, providing specificity between the originating physical processor (a bus agent) versus other agents on the bus. Sub-field encoding for agent specificity is shown in Table 18-3.

**Table 18-3. Agent Specificity Encoding within a Non-Architectural Umask**

| IA32_PERFEVTSELx MSRs | |
|---|---|
| **Bit 13 Encoding** | **Description** |
| 0 | This agent |
| 1 | Include all agents |

Some microarchitectural conditions are detectable only from the originating core. In such cases, unit mask does not support core-specificity or agent-specificity encodings. These are referred to as core-only conditions.

Some microarchitectural conditions allow detection specificity that includes or excludes the action of hardware prefetches. A two-bit encoding may be supported to qualify hardware prefetch actions. Typically, this applies only to some L2 or bus events. The sub-field encoding for hardware prefetch qualification is shown in Table 18-4.

Table 18-4. HW Prefetch Qualification Encoding within a Non-Architectural Umask

| IA32_PERFEVTSELx MSRs | |
|---|---|
| **Bit 13:12 Encoding** | **Description** |
| 11B | All inclusive |
| 10B | Reserved |
| 01B | Hardware prefetch only |
| 00B | Exclude hardware prefetch |

Some performance events may (a) support none of the three event-specific qualification encodings (b) may support core-specificity and agent specificity simultaneously (c) or may support core-specificity and hardware prefetch qualification simultaneously. Agent-specificity and hardware prefetch qualification are mutually exclusive.

In addition, some L2 events permit qualifications that distinguish cache coherent states. The sub-field definition for cache coherency state qualification is shown in Table 18-5. If no bits in the MESI qualification sub-field are set for an event that requires setting MESI qualification bits, the event count will not increment.

Table 18-5. MESI Qualification Definitions within a Non-Architectural Umask

| IA32_PERFEVTSELx MSRs | |
|---|---|
| **Bit Position 11:8** | **Description** |
| Bit 11 | Counts modified state |
| Bit 10 | Counts exclusive state |
| Bit 9 | Counts shared state |
| Bit 8 | Counts Invalid state |

## 18.4 PERFORMANCE MONITORING (PROCESSORS BASED ON INTEL® CORE™ MICROARCHITECTURE)

In addition to architectural performance monitoring, processors based on the Intel Core microarchitecture support non-architectural performance monitoring events.

Architectural performance events can be collected using general-purpose performance counters. Non-architectural performance events can be collected using general-purpose performance counters (coupled with two IA32_PERFEVTSELx MSRs for detailed event configurations), or fixed-function performance counters (see Section 18.4.1). IA32_PERFEVTSELx MSRs are architectural; their layout is shown in Figure 18-1. Starting with Intel Core 2 processor T 7700, fixed-function performance counters and associated counter control and status MSR becomes part of architectural performance monitoring version 2 facilities (see also Section 18.2.2).

Non-architectural performance events in processors based on Intel Core microarchitecture use event select values that are model-specific. Valid event mask (Umask) bits are listed in Chapter 19. The UMASK field may contain sub-fields identical to those listed in Table 18-2, Table 18-3, Table 18-4, and Table 18-5. One or more of these sub-fields may apply to specific events on an event-by-event basis. Details are listed in Table 19-19 in Chapter 19, "Performance-Monitoring Events."

In addition, the UMASK filed may also contain a sub-field that allows detection specificity related to snoop responses. Bits of the snoop response qualification sub-field are defined in Table 18-6.

Table 18-6. Bus Snoop Qualification Definitions within a Non-Architectural Umask

| IA32_PERFEVTSELx MSRs | |
|---|---|
| **Bit Position 11:8** | **Description** |
| Bit 11 | HITM response |
| Bit 10 | Reserved |

Table 18-6. Bus Snoop Qualification Definitions within a Non-Architectural Umask

| IA32_PERFEVTSELx MSRs | |
|---|---|
| **Bit Position 11:8** | **Description** |
| Bit 9 | HIT response |
| Bit 8 | CLEAN response |

There are also non-architectural events that support qualification of different types of snoop operation. The corresponding bit field for snoop type qualification are listed in Table 18-7.

Table 18-7. Snoop Type Qualification Definitions within a Non-Architectural Umask

| IA32_PERFEVTSELx MSRs | |
|---|---|
| **Bit Position 9:8** | **Description** |
| Bit 9 | CMP2I snoops |
| Bit 8 | CMP2S snoops |

No more than one sub-field of MESI, snoop response, and snoop type qualification sub-fields can be supported in a performance event.

**NOTE**

Software must write known values to the performance counters prior to enabling the counters. The content of general-purpose counters and fixed-function counters are undefined after INIT or RESET.

## 18.4.1 Fixed-function Performance Counters

Processors based on Intel Core microarchitecture provide three fixed-function performance counters. Bits beyond the width of the fixed counter are reserved and must be written as zeros. Model-specific fixed-function performance counters on processors that support Architectural Perfmon version 1 are 40 bits wide.

Each of the fixed-function counter is dedicated to count a pre-defined performance monitoring events. The performance monitoring events associated with fixed-function counters and the addresses of these counters are listed in Table 18-8.

Table 18-8. Association of Fixed-Function Performance Counters with Architectural Performance Events

| Event Name | Fixed-Function PMC | PMC Address |
|---|---|---|
| INST_RETIRED.ANY | MSR_PERF_FIXED_CTR0/IA32_FIXED_CTR0 | 309H |
| CPU_CLK_UNHALTED.CORE | MSR_PERF_FIXED_CTR1//IA32_FIXED_CTR1 | 30AH |
| CPU_CLK_UNHALTED.REF | MSR_PERF_FIXED_CTR2//IA32_FIXED_CTR2 | 30BH |

Programming the fixed-function performance counters does not involve any of the IA32_PERFEVTSELx MSRs, and does not require specifying any event masks. Instead, the MSR MSR_PERF_FIXED_CTR_CTRL provides multiple sets of 4-bit fields; each 4-bit field controls the operation of a fixed-function performance counter (PMC). See Figures 18-10. Two sub-fields are defined for each control. See Figure 18-10; bit fields are:

- **Enable field (low 2 bits in each 4-bit control) —** When bit 0 is set, performance counting is enabled in the corresponding fixed-function performance counter to increment when the target condition associated with the architecture performance event occurs at ring 0.

  When bit 1 is set, performance counting is enabled in the corresponding fixed-function performance counter to increment when the target condition associated with the architecture performance event occurs at ring greater than 0.

Writing 0 to both bits stops the performance counter. Writing 11B causes the counter to increment irrespective of privilege levels.

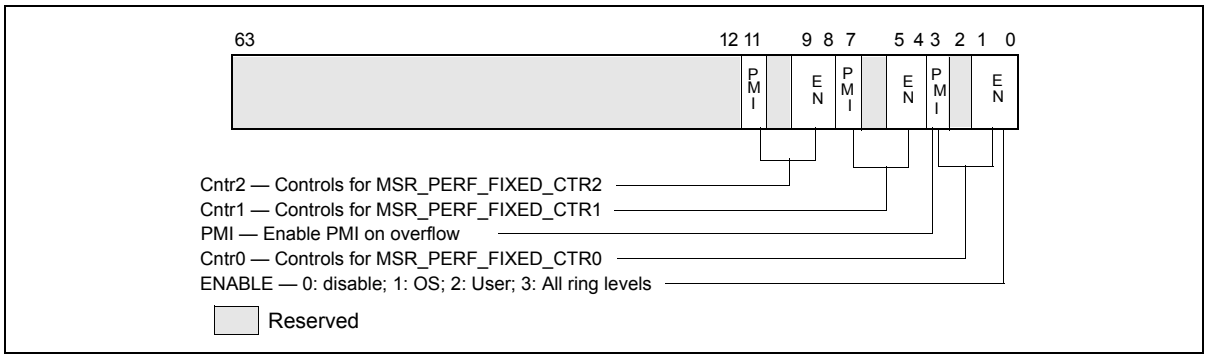

Figure 18-10. Layout of MSR_PERF_FIXED_CTR_CTRL MSR

- **PMI field (fourth bit in each 4-bit control)** — When set, the logical processor generates an exception through its local APIC on overflow condition of the respective fixed-function counter.

## 18.4.2 Global Counter Control Facilities

Processors based on Intel Core microarchitecture provides simplified performance counter control that simplifies the most frequent operations in programming performance events, i.e. enabling/disabling event counting and checking the status of counter overflows. This is done by the following three MSRs:

- MSR_PERF_GLOBAL_CTRL enables/disables event counting for all or any combination of fixed-function PMCs (MSR_PERF_FIXED_CTRx) or general-purpose PMCs via a single WRMSR.
- MSR_PERF_GLOBAL_STATUS allows software to query counter overflow conditions on any combination of fixed-function PMCs (MSR_PERF_FIXED_CTRx) or general-purpose PMCs via a single RDMSR.
- MSR_PERF_GLOBAL_OVF_CTRL allows software to clear counter overflow conditions on any combination of fixed-function PMCs (MSR_PERF_FIXED_CTRx) or general-purpose PMCs via a single WRMSR.

MSR_PERF_GLOBAL_CTRL MSR provides single-bit controls to enable counting in each performance counter (see Figure 18-11). Each enable bit in MSR_PERF_GLOBAL_CTRL is AND'ed with the enable bits for all privilege levels in the respective IA32_PERFEVTSELx or MSR_PERF_FIXED_CTR_CTRL MSRs to start/stop the counting of respective counters. Counting is enabled if the AND'ed results is true; counting is disabled when the result is false.

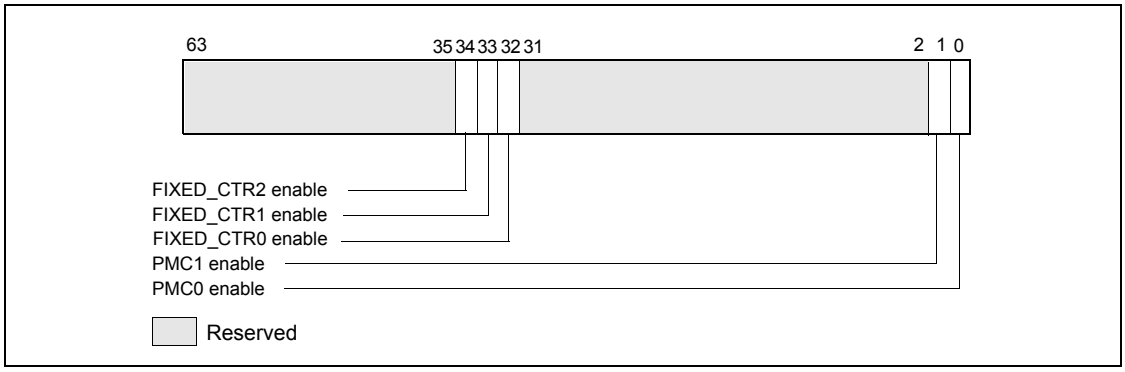

Figure 18-11. Layout of MSR_PERF_GLOBAL_CTRL MSR

MSR_PERF_GLOBAL_STATUS MSR provides single-bit status used by software to query the overflow condition of each performance counter. The MSR also provides additional status bit to indicate overflow conditions when coun-

ters are programmed for precise-event-based sampling (PEBS). The MSR_PERF_GLOBAL_STATUS MSR also provides a CondChgd bit to indicate changes to the state of performance monitoring hardware (see Figure 18-12). A value of 1 in bits 34:32, 1, 0 indicates an overflow condition has occurred in the associated counter.

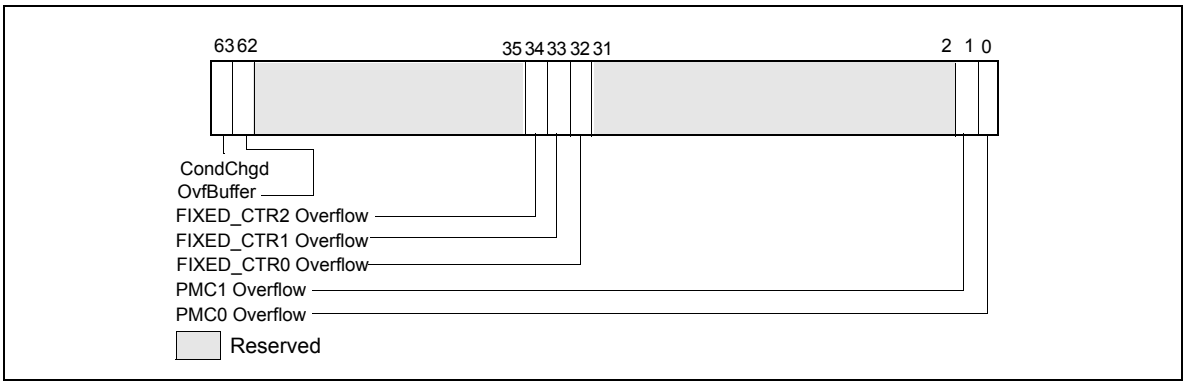

**Figure 18-12. Layout of MSR_PERF_GLOBAL_STATUS MSR**

When a performance counter is configured for PEBS, an overflow condition in the counter will arm PEBS. On the subsequent event following overflow, the processor will generate a PEBS event. On a PEBS event, the processor will perform bounds checks based on the parameters defined in the DS Save Area (see Section 17.4.9). Upon successful bounds checks, the processor will store the data record in the defined buffer area, clear the counter overflow status, and reload the counter. If the bounds checks fail, the PEBS will be skipped entirely. In the event that the PEBS buffer fills up, the processor will set the OvfBuffer bit in MSR_PERF_GLOBAL_STATUS.

MSR_PERF_GLOBAL_OVF_CTL MSR allows software to clear overflow the indicators for general-purpose or fixed-function counters via a single WRMSR (see Figure 18-13). Clear overflow indications when:

- Setting up new values in the event select and/or UMASK field for counting or sampling
- Reloading counter values to continue sampling
- Disabling event counting or sampling

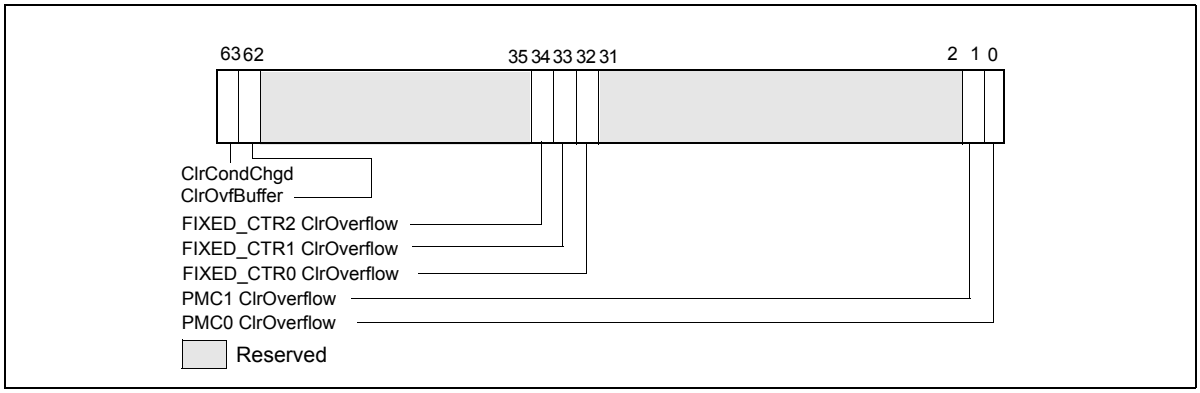

**Figure 18-13. Layout of MSR_PERF_GLOBAL_OVF_CTRL MSR**

## 18.4.3 At-Retirement Events

Many non-architectural performance events are impacted by the speculative nature of out-of-order execution. A subset of non-architectural performance events on processors based on Intel Core microarchitecture are enhanced with a tagging mechanism (similar to that found in Intel NetBurst® microarchitecture) that exclude contributions that arise from speculative execution. The at-retirement events available in processors based on Intel Core micro-architecture does not require special MSR programming control (see Section 18.13.6, “At-Retirement Counting”),

but is limited to IA32_PMC0. See Table 18-9 for a list of events available to processors based on Intel Core micro-architecture.

**Table 18-9. At-Retirement Performance Events for Intel Core Microarchitecture**

| Event Name | UMask | Event Select |
|---|---|---|
| ITLB_MISS_RETIRED | 00H | C9H |
| MEM_LOAD_RETIRED.L1D_MISS | 01H | CBH |
| MEM_LOAD_RETIRED.L1D_LINE_MISS | 02H | CBH |
| MEM_LOAD_RETIRED.L2_MISS | 04H | CBH |
| MEM_LOAD_RETIRED.L2_LINE_MISS | 08H | CBH |
| MEM_LOAD_RETIRED.DTLB_MISS | 10H | CBH |

## 18.4.4 Precise Event Based Sampling (PEBS)

Processors based on Intel Core microarchitecture also support precise event based sampling (PEBS). This feature was introduced by processors based on Intel NetBurst microarchitecture.

PEBS uses a debug store mechanism and a performance monitoring interrupt to store a set of architectural state information for the processor. The information provides architectural state of the instruction executed after the instruction that caused the event (See Section 18.4.4.2).

In cases where the same instruction causes BTS and PEBS to be activated, PEBS is processed before BTS are processed. The PMI request is held until the processor completes processing of PEBS and BTS.

For processors based on Intel Core microarchitecture, events that support precise sampling are listed in Table 18-10. The procedure for detecting availability of PEBS is the same as described in Section 18.13.7.1.

**Table 18-10. PEBS Performance Events for Intel Core Microarchitecture**

| Event Name | UMask | Event Select |
|---|---|---|
| INSTR_RETIRED.ANY_P | 00H | C0H |
| X87_OPS_RETIRED.ANY | FEH | C1H |
| BR_INST_RETIRED.MISPRED | 00H | C5H |
| SIMD_INST_RETIRED.ANY | 1FH | C7H |
| MEM_LOAD_RETIRED.L1D_MISS | 01H | CBH |
| MEM_LOAD_RETIRED.L1D_LINE_MISS | 02H | CBH |
| MEM_LOAD_RETIRED.L2_MISS | 04H | CBH |
| MEM_LOAD_RETIRED.L2_LINE_MISS | 08H | CBH |
| MEM_LOAD_RETIRED.DTLB_MISS | 10H | CBH |

### 18.4.4.1 Setting up the PEBS Buffer

For processors based on Intel Core microarchitecture, PEBS is available using IA32_PMC0 only. Use the following procedure to set up the processor and IA32_PMC0 counter for PEBS:

1. Set up the precise event buffering facilities. Place values in the precise event buffer base, precise event index, precise event absolute maximum, precise event interrupt threshold, and precise event counter reset fields of the DS buffer management area. In processors based on Intel Core microarchitecture, PEBS records consist of 64-bit address entries. See Figure 17-8 to set up the precise event records buffer in memory.
2. Enable PEBS. Set the Enable PEBS on PMC0 flag (bit 0) in IA32_PEBS_ENABLE MSR.
3. Set up the IA32_PMC0 performance counter and IA32_PERFEVTSEL0 for an event listed in Table 18-10.

### 18.4.4.2 PEBS Record Format

The PEBS record format may be extended across different processor implementations. The IA32_PERF_CAPABILITES MSR defines a mechanism for software to handle the evolution of PEBS record format in processors that support architectural performance monitoring with version id equals 2 or higher. The bit fields of IA32_PERF_CAPABILITES are defined in Table 35-2 of Chapter 35, "Model-Specific Registers (MSRs)". The relevant bit fields that governs PEBS are:

- PEBSTrap [bit 6]: When set, PEBS recording is trap-like. After the PEBS-enabled counter has overflowed, PEBS record is recorded for the next PEBS-able event at the completion of the sampled instruction causing the PEBS event. When clear, PEBS recording is fault-like. The PEBS record is recorded before the sampled instruction causing the PEBS event.
- PEBSSaveArchRegs [bit 7]: When set, PEBS will save architectural register and state information according to the encoded value of the PEBSRecordFormat field. On processors based on Intel Core microarchitecture, this bit is always 1
- PEBSRecordFormat [bits 11:8]: Valid encodings are:
  - 0000B: Only general-purpose registers, instruction pointer and RFLAGS registers are saved in each PEBS record (seeSection 18.13.7).

### 18.4.4.3 Writing a PEBS Interrupt Service Routine

The PEBS facilities share the same interrupt vector and interrupt service routine (called the DS ISR) with the non-precise event-based sampling and BTS facilities. To handle PEBS interrupts, PEBS handler code must be included in the DS ISR. See Section 17.4.9.1, "DS Save Area and IA-32e Mode Operation," for guidelines when writing the DS ISR.

The service routine can query MSR_PERF_GLOBAL_STATUS to determine which counter(s) caused of overflow condition. The service routine should clear overflow indicator by writing to MSR_PERF_GLOBAL_OVF_CTL.

A comparison of the sequence of requirements to program PEBS for processors based on Intel Core and Intel NetBurst microarchitectures is listed in Table 18-11.

**Table 18-11. Requirements to Program PEBS**

| | For Processors based on Intel Core microarchitecture | For Processors based on Intel NetBurst microarchitecture |
|---|---|---|
| Verify PEBS support of processor/OS | ▪ IA32_MISC_ENABLE.EMON_AVAILABE (bit 7) is set.<br>▪ IA32_MISC_ENABLE.PEBS_UNAVAILABE (bit 12) is clear. | |
| Ensure counters are in disabled | On initial set up or changing event configurations, write MSR_PERF_GLOBAL_CTRL MSR (38FH) with 0.<br>On subsequent entries:<br>▪ Clear all counters if "Counter Freeze on PMI" is not enabled.<br>▪ If IA32_DebugCTL.Freeze is enabled, counters are automatically disabled.<br>Counters MUST be stopped before writing.[1] | Optional |
| Disable PEBS. | Clear ENABLE PMC0 bit in IA32_PEBS_ENABLE MSR (3F1H). | Optional |
| Check overflow conditions. | Check MSR_PERF_GLOBAL_STATUS MSR (38EH) handle any overflow conditions. | Check OVF flag of each CCCR for overflow condition |
| Clear overflow status. | Clear MSR_PERF_GLOBAL_STATUS MSR (38EH) using IA32_PERF_GLOBAL_OVF_CTRL MSR (390H). | Clear OVF flag of each CCCR. |
| Write "sample-after" values. | Configure the counter(s) with the sample after value. | |

**Table 18-11. Requirements to Program PEBS (Contd.)**

| | For Processors based on Intel Core microarchitecture | For Processors based on Intel NetBurst microarchitecture |
|---|---|---|
| Configure specific counter configuration MSR. | ▪ Set local enable bit 22 - 1.<br>▪ Do NOT set local counter PMI/INT bit, bit 20 - 0.<br>▪ Event programmed must be PEBS capable. | ▪ Set appropriate OVF_PMI bits - 1.<br>▪ Only CCCR for MSR_IQ_COUNTER4 support PEBS. |
| Allocate buffer for PEBS states. | Allocate a buffer in memory for the precise information. | |
| Program the IA32_DS_AREA MSR. | Program the IA32_DS_AREA MSR. | |
| Configure the PEBS buffer management records. | Configure the PEBS buffer management records in the DS buffer management area. | |
| Configure/Enable PEBS. | Set Enable PMC0 bit in IA32_PEBS_ENABLE MSR (3F1H). | Configure MSR_PEBS_ENABLE, MSR_PEBS_MATRIX_VERT and MSR_PEBS_MATRIX_HORZ as needed. |
| Enable counters. | Set Enable bits in MSR_PERF_GLOBAL_CTRL MSR (38FH). | Set each CCCR enable bit 12 - 1. |

**NOTES:**

1. Counters read while enabled are not guaranteed to be precise with event counts that occur in timing proximity to the RDMSR.

#### 18.4.4.4 Re-configuring PEBS Facilities

When software needs to reconfigure PEBS facilities, it should allow a quiescent period between stopping the prior event counting and setting up a new PEBS event. The quiescent period is to allow any latent residual PEBS records to complete its capture at their previously specified buffer address (provided by IA32_DS_AREA).

## 18.5 PERFORMANCE MONITORING (PROCESSORS BASED ON INTEL® ATOM™ MICROARCHITECTURE)

Intel Atom processor family supports architectural performance monitoring capability with version ID 3 (see Section 18.2.2.2) and a host of non-architectural monitoring capabilities. The initial implementation of Intel Atom processor family provides two general-purpose performance counters (IA32_PMC0, IA32_PMC1) and three fixed-function performance counters (IA32_FIXED_CTR0, IA32_FIXED_CTR1, IA32_FIXED_CTR2).

Non-architectural performance monitoring in Intel Atom processor family uses the IA32_PERFEVTSELx MSR to configure a set of non-architecture performance monitoring events to be counted by the corresponding general-purpose performance counter. The list of non-architectural performance monitoring events is listed in Table 19-21.

Architectural and non-architectural performance monitoring events in Intel Atom processor family support thread qualification using bit 21 of IA32_PERFEVTSELx MSR.

The bit fields within each IA32_PERFEVTSELx MSR are defined in Figure 18-6 and described in Section 18.2.1.1 and Section 18.2.2.2.

Valid event mask (Umask) bits are listed in Chapter 19. The UMASK field may contain sub-fields that provide the same qualifying actions like those listed in Table 18-2, Table 18-3, Table 18-4, and Table 18-5. One or more of these sub-fields may apply to specific events on an event-by-event basis. Details are listed in Table 19-21 in Chapter 19, "Performance-Monitoring Events." Precise Event Based Monitoring is supported using IA32_PMC0 (see also Section 17.4.9, "BTS and DS Save Area").

# 18.6 PERFORMANCE MONITORING (PROCESSORS BASED ON THE SILVERMONT MICROARCHITECTURE)

Intel processors based on the Silvermont microarchitecture support architectural performance monitoring capability with version ID 3 (see Section 18.2.2.2) and a host of non-architectural monitoring capabilities. Processors based on the Silvermont microarchitecture provide two general-purpose performance counters (IA32_PMC0, IA32_PMC1) and three fixed-function performance counters (IA32_FIXED_CTR0, IA32_FIXED_CTR1, IA32_FIXED_CTR2).

Non-architectural performance monitoring in the Silvermont microarchitecture uses the IA32_PERFEVTSELx MSR to configure a set of non-architecture performance monitoring events to be counted by the corresponding general-purpose performance counter. The list of non-architectural performance monitoring events is listed in Table 19-20.

The bit fields (except bit 21) within each IA32_PERFEVTSELx MSR are defined in Figure 18-6 and described in Section 18.2.1.1 and Section 18.2.2.2. Architectural and non-architectural performance monitoring events in the Silvermont microarchitecture ignore the AnyThread qualification regardless of its setting in IA32_PERFEVTSELx MSR.

## 18.6.1 Enhancements of Performance Monitoring in the Processor Core

The notable enhancements in the monitoring of performance events in the processor core include:

- The width of counter reported by CPUID.0AH:EAX[23:16] is 40 bits.
- Off-core response counting facility. This facility in the processor core allows software to count certain transaction responses between the processor core to sub-systems outside the processor core (uncore). Counting off-core response requires additional event qualification configuration facility in conjunction with IA32_PERFEVTSELx. Two off-core response MSRs are provided to use in conjunction with specific event codes that must be specified with IA32_PERFEVTSELx.
- Average request latency measurement. The off-core response counting facility can be combined to use two performance counters to count the occurrences and weighted cycles of transaction requests.

### 18.6.1.1 Precise Event Based Sampling (PEBS)

Processors based on the Silvermont microarchitecture support precise event based sampling (PEBS). PEBS is supported using IA32_PMC0 (see also Section 17.4.9, “BTS and DS Save Area”).

PEBS uses a debug store mechanism to store a set of architectural state information for the processor. The information provides architectural state of the instruction executed after the instruction that caused the event (See Section 18.4.4).

The list of PEBS events supported in the Silvermont microarchitecture is shown in Table 18-12.

**Table 18-12. PEBS Performance Events for the Silvermont Microarchitecture**

| Event Name | Event Select | Sub-event | UMask |
|---|---|---|---|
| BR_INST_RETIRED | C4H | ALL_BRANCHES | 00H |
| | | JCC | 7EH |
| | | TAKEN_JCC | FEH |
| | | CALL | F9H |
| | | REL_CALL | FDH |
| | | IND_CALL | FBH |
| | | NON_RETURN_IND | EBH |
| | | FAR_BRANCH | BFH |
| | | RETURN | F7H |

Table 18-12. PEBS Performance Events for the Silvermont Microarchitecture (Contd.)

## 18.6.2 Offcore Response Event

Event number 0B7H support offcore response monitoring using an associated configuration MSR, MSR_OFFCORE_RSP0 (address 1A6H) in conjunction with umask value 01H or MSR_OFFCORE_RSP1 (address 1A7H) in conjunction with umask value 02H. Table 19-20 lists the event code, mask value and additional off-core configuration MSR that must be programmed to count off-core response events using IA32_PMCx.

Table 18-14. OffCore Response Event Encoding

| Counter | Event code | UMask | Required Off-core Response MSR |
|---|---|---|---|
| PMC0-3 | B7H | 01H | MSR_OFFCORE_RSP0 (address 1A6H) |

**Table 18-14. OffCore Response Event Encoding (Contd.)**

| Counter | Event code | UMask | Required Off-core Response MSR |
|---|---|---|---|
| PMC0-3 | B7H | 02H | MSR_OFFCORE_RSP1 (address 1A7H) |

The layout of MSR_OFFCORE_RSP0 and MSR_OFFCORE_RSP1 are shown in Figure 18-32 and Figure 18-33. Bits 15:0 specifies the request type of a transaction request to the uncore. Bits 30:16 specifies supplier information, bits 37:31 specifies snoop response information.

Additionally, MSR_OFFCORE_RSP0 provides bit 38 to enable measurement of average latency of specific type of offcore transaction requests using two programmable counter simultaneously, see Section 18.6.3 for details.

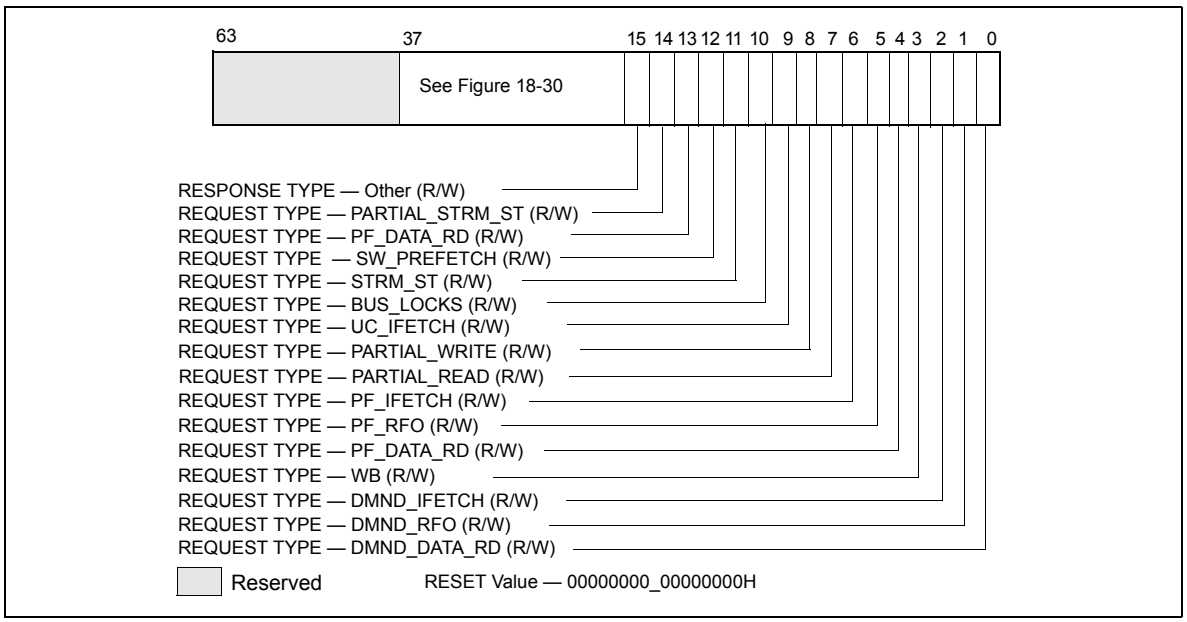

**Figure 18-14. Request_Type Fields for MSR_OFFCORE_RSPx**

**Table 18-15. MSR_OFFCORE_RSPx Request_Type Field Definition**

| Bit Name | Offset | Description |
|---|---|---|
| DMND_DATA_RD | 0 | (R/W). Counts the number of demand and DCU prefetch data reads of full and partial cachelines as well as demand data page table entry cacheline reads. Does not count L2 data read prefetches or instruction fetches. |
| DMND_RFO | 1 | (R/W). Counts the number of demand and DCU prefetch reads for ownership (RFO) requests generated by a write to data cacheline. Does not count L2 RFO prefetches. |
| DMND_IFETCH | 2 | (R/W). Counts the number of demand and DCU prefetch instruction cacheline reads. Does not count L2 code read prefetches. |
| WB | 3 | (R/W). Counts the number of writeback (modified to exclusive) transactions. |
| PF_DATA_RD | 4 | (R/W). Counts the number of data cacheline reads generated by L2 prefetchers. |
| PF_RFO | 5 | (R/W). Counts the number of RFO requests generated by L2 prefetchers. |
| PF_IFETCH | 6 | (R/W). Counts the number of code reads generated by L2 prefetchers. |
| PARTIAL_READ | 7 | (R/W). Counts the number of demand reads of partial cache lines (including UC and WC). |
| PARTIAL_WRITE | 8 | (R/W). Counts the number of demand RFO requests to write to partial cache lines (includes UC, WT and WP) |
| UC_IFETCH | 9 | (R/W). Counts the number of UC instruction fetches. |

Table 18-15. MSR_OFFCORE_RSPx Request_Type Field Definition (Contd.)

| Bit Name | Offset | Description |
|---|---|---|
| BUS_LOCKS | 10 | (R/W). Bus lock and split lock requests |
| STRM_ST | 11 | (R/W). Streaming store requests |
| SW_PREFETCH | 12 | (R/W). Counts software prefetch requests |
| PF_DATA_RD | 13 | (R/W). Counts DCU hardware prefetcher data read requests |
| PARTIAL_STRM_ST | 14 | (R/W). Streaming store requests |
| ANY | 15 | (R/W). Any request that crosses IDI, including I/O. |

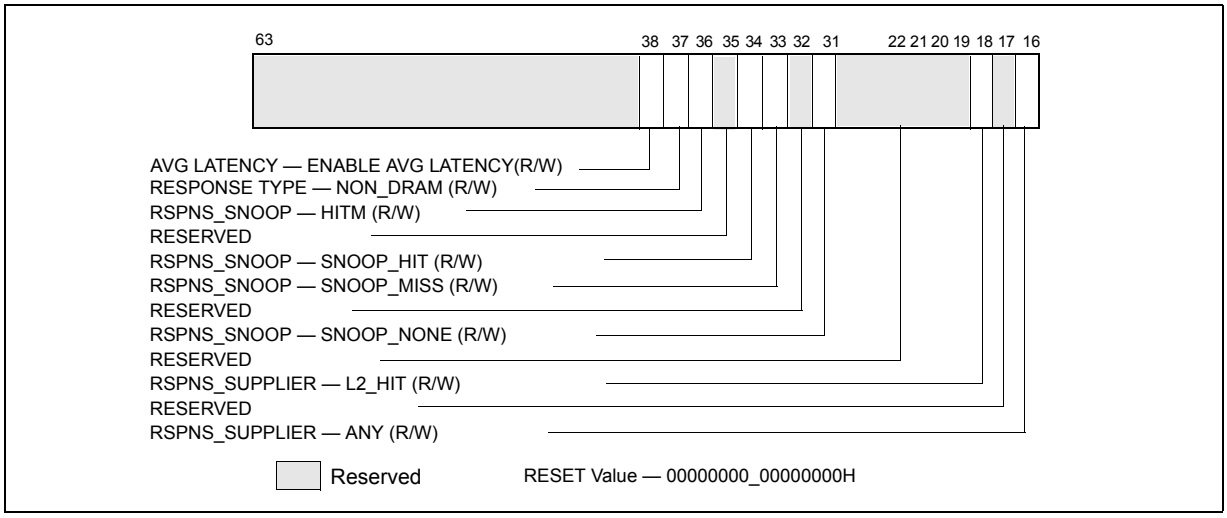

Figure 18-15. Response_Supplier and Snoop Info Fields for MSR_OFFCORE_RSPx

To properly program this extra register, software must set at least one request type bit and a valid response type pattern. Otherwise, the event count reported will be zero. It is permissible and useful to set multiple request and response type bits in order to obtain various classes of off-core response events. Although MSR_OFFCORE_RSPx allow an agent software to program numerous combinations that meet the above guideline, not all combinations produce meaningful data.

Table 18-16. MSR_OFFCORE_RSP_x Response Supplier Info Field Definition

| Subtype | Bit Name | Offset | Description |
|---|---|---|---|
| Common | Any | 16 | (R/W). Catch all value for any response types. |
| Supplier Info | Reserved | 17 | Reserved |
| | L2_HIT | 18 | (R/W). Cache reference hit L2 in either M/E/S states. |
| | Reserved | 30:19 | Reserved |

To specify a complete offcore response filter, software must properly program bits in the request and response type fields. A valid request type must have at least one bit set in the non-reserved bits of 15:0. A valid response type must be a non-zero value of the following expression:

ANY | [('OR' of Supplier Info Bits) & ('OR' of Snoop Info Bits)]

If "ANY" bit is set, the supplier and snoop info bits are ignored.

Table 18-17. MSR_OFFCORE_RSPx Snoop Info Field Definition

| Subtype | Bit Name | Offset | Description |
|---|---|---|---|
| Snoop Info | SNP_NONE | 31 | (R/W). No details on snoop-related information |
| | Reserved | 32 | Reserved |
| | SNOOP_MISS | 33 | (R/W). Counts the number of snoop misses when L2 misses |
| | SNOOP_HIT | 34 | (R/W). Counts the number of snoops hit in the other module where no modified copies were found |
| | Reserved | 35 | Reserved |
| | HITM | 36 | (R/W). Counts the number of snoops hit in the other module where modified copies were found in other core's L1 cache. |
| | NON_DRAM | 37 | (R/W). Target was non-DRAM system address. This includes MMIO transactions. |
| | AVG_LATENCY | 38 | (R/W). Enable average latency measurement by counting weighted cycles of outstanding offcore requests of the request type specified in bits 15:0 and any response (bits 37:16 cleared to 0).<br>This bit is available in MSR_OFFCORE_RESP0. The weighted cycles is accumulated in the specified programmable counter IA32_PMCx and the occurrence of specified requests are counted in the other programmable counter. |

### 18.6.3 Average Offcore Request Latency Measurement

Measurement of average latency of offcore transaction requests can be enabled using MSR_OFFCORE_RSP0.[bit 38] with the choice of request type specified in MSR_OFFCORE_RSP0.[bit 15:0] and MSR_OFFCORE_RSP0.[bit 37:16] set to 0.

When average latency measurement is enabled, e.g. with IA32_PERFEVTSEL0.[bits 15:0] = 01B7H and chosen value of MSR_OFFCORE_RSP0, IA32_PMC0 will accumulate weighted cycles of outstanding transaction requests for the specified transaction request type. At the same time, IA32_PMC1 should be configured to accumulate the number of occurrences each time a new transaction request of specified type is made.

## 18.7 PERFORMANCE MONITORING FOR PROCESSORS BASED ON INTEL® MICROARCHITECTURE CODE NAME NEHALEM

Intel Core i7 processor family[1] supports architectural performance monitoring capability with version ID 3 (see Section 18.2.2.2) and a host of non-architectural monitoring capabilities. The Intel Core i7 processor family is based on Intel® microarchitecture code name Nehalem, and provides four general-purpose performance counters (IA32_PMC0, IA32_PMC1, IA32_PMC2, IA32_PMC3) and three fixed-function performance counters (IA32_FIXED_CTR0, IA32_FIXED_CTR1, IA32_FIXED_CTR2) in the processor core.

Non-architectural performance monitoring in Intel Core i7 processor family uses the IA32_PERFEVTSELx MSR to configure a set of non-architecture performance monitoring events to be counted by the corresponding general-purpose performance counter. The list of non-architectural performance monitoring events is listed in Table 19-21. Non-architectural performance monitoring events fall into two broad categories:

- Performance monitoring events in the processor core: These include many events that are similar to performance monitoring events available to processor based on Intel Core microarchitecture. Additionally, there are several enhancements in the performance monitoring capability for detecting microarchitectural conditions in the processor core or in the interaction of the processor core to the off-core sub-systems in the

1. Intel Xeon processor 5500 series and 3400 series are also based on Intel microarchitecture code name Nehalem, so the performance monitoring facilities described in this section generally also apply.

physical processor package. The off-core sub-systems in the physical processor package is loosely referred to as "uncore".

- Performance monitoring events in the uncore: The uncore sub-system is shared by more than one processor cores in the physical processor package. It provides additional performance monitoring facility outside of IA32_PMCx and performance monitoring events that are specific to the uncore sub-system.

Architectural and non-architectural performance monitoring events in Intel Core i7 processor family support thread qualification using bit 21 of IA32_PERFEVTSELx MSR.

The bit fields within each IA32_PERFEVTSELx MSR are defined in Figure 18-6 and described in Section 18.2.1.1 and Section 18.2.2.2.

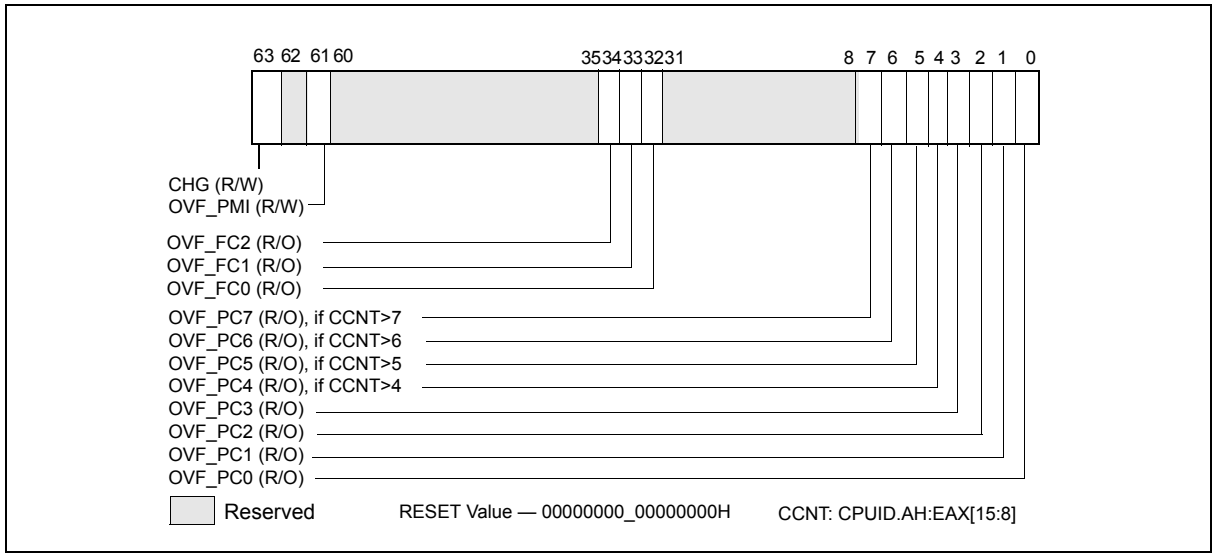

Figure 18-16. IA32_PERF_GLOBAL_STATUS MSR

## 18.7.1 Enhancements of Performance Monitoring in the Processor Core

The notable enhancements in the monitoring of performance events in the processor core include:

- Four general purpose performance counters, IA32_PMCx, associated counter configuration MSRs, IA32_PERFEVTSELx, and global counter control MSR supporting simplified control of four counters. Each of the four performance counter can support precise event based sampling (PEBS) and thread-qualification of architectural and non-architectural performance events. Width of IA32_PMCx supported by hardware has been increased. The width of counter reported by CPUID.0AH:EAX[23:16] is 48 bits. The PEBS facility in Intel microarchitecture code name Nehalem has been enhanced to include new data format to capture additional information, such as load latency.
- Load latency sampling facility. Average latency of memory load operation can be sampled using load-latency facility in processors based on Intel microarchitecture code name Nehalem. This field measures the load latency from load's first dispatch of till final data writeback from the memory subsystem. The latency is reported for retired demand load operations and in core cycles (it accounts for re-dispatches). This facility is used in conjunction with the PEBS facility.
- Off-core response counting facility. This facility in the processor core allows software to count certain transaction responses between the processor core to sub-systems outside the processor core (uncore). Counting off-core response requires additional event qualification configuration facility in conjunction with IA32_PERFEVTSELx. Two off-core response MSRs are provided to use in conjunction with specific event codes that must be specified with IA32_PERFEVTSELx.

### 18.7.1.1 Precise Event Based Sampling (PEBS)

All four general-purpose performance counters, IA32_PMCx, can be used for PEBS if the performance event supports PEBS. Software uses IA32_MISC_ENABLE[7] and IA32_MISC_ENABLE[12] to detect whether the performance monitoring facility and PEBS functionality are supported in the processor. The MSR IA32_PEBS_ENABLE provides 4 bits that software must use to enable which IA32_PMCx overflow condition will cause the PEBS record to be captured.

Additionally, the PEBS record is expanded to allow latency information to be captured. The MSR IA32_PEBS_ENABLE provides 4 additional bits that software must use to enable latency data recording in the PEBS record upon the respective IA32_PMCx overflow condition. The layout of IA32_PEBS_ENABLE for processors based on Intel microarchitecture code name Nehalem is shown in Figure 18-17.

When a counter is enabled to capture machine state (PEBS_EN_PMCx = 1), the processor will write machine state information to a memory buffer specified by software as detailed below. When the counter IA32_PMCx overflows from maximum count to zero, the PEBS hardware is armed.

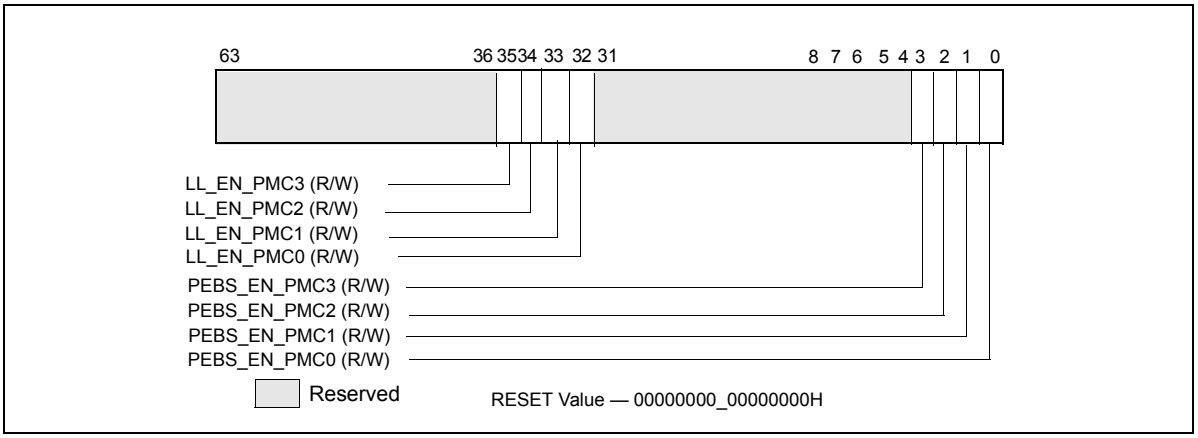

Figure 18-17. Layout of IA32_PEBS_ENABLE MSR

Upon occurrence of the next PEBS event, the PEBS hardware triggers an assist and causes a PEBS record to be written. The format of the PEBS record is indicated by the bit field IA32_PERF_CAPABILITIES[11:8] (see Figure 18-43).

The behavior of PEBS assists is reported by IA32_PERF_CAPABILITIES[6] (see Figure 18-43). The return instruction pointer (RIP) reported in the PEBS record will point to the instruction after (+1) the instruction that causes the PEBS assist. The machine state reported in the PEBS record is the machine state after the instruction that causes the PEBS assist is retired. For instance, if the instructions:

mov eax, [eax] ; causes PEBS assist

nop

are executed, the PEBS record will report the address of the nop, and the value of EAX in the PEBS record will show the value read from memory, not the target address of the read operation.

The PEBS record format is shown in Table 18-18, and each field in the PEBS record is 64 bits long. The PEBS record format, along with debug/store area storage format, does not change regardless of IA-32e mode is active or not. CPUID.01H:ECX.DTES64[bit 2] reports whether the processor's DS storage format support is mode-independent. When set, it uses 64-bit DS storage format.

Table 18-18. PEBS Record Format for Intel Core i7 Processor Family

| Byte Offset | Field | Byte Offset | Field |
|---|---|---|---|
| 00H | R/EFLAGS | 58H | R9 |
| 08H | R/EIP | 60H | R10 |

Table 18-18. PEBS Record Format for Intel Core i7 Processor Family

| Byte Offset | Field | Byte Offset | Field |
|---|---|---|---|
| 10H | R/EAX | 68H | R11 |
| 18H | R/EBX | 70H | R12 |
| 20H | R/ECX | 78H | R13 |
| 28H | R/EDX | 80H | R14 |
| 30H | R/ESI | 88H | R15 |
| 38H | R/EDI | 90H | IA32_PERF_GLOBAL_STATUS |
| 40H | R/EBP | 98H | Data Linear Address |
| 48H | R/ESP | A0H | Data Source Encoding |
| 50H | R8 | A8H | Latency value (core cycles) |

In IA-32e mode, the full 64-bit value is written to the register. If the processor is not operating in IA-32e mode, 32-bit value is written to registers with bits 63:32 zeroed. Registers not defined when the processor is not in IA-32e mode are written to zero.

Bytes AFH:90H are enhancement to the PEBS record format. Support for this enhanced PEBS record format is indicated by IA32_PERF_CAPABILITIES[11:8] encoding of 0001B.

The value written to bytes 97H:90H is the state of the IA32_PERF_GLOBAL_STATUS register before the PEBS assist occurred. This value is written so software can determine which counters overflowed when this PEBS record was written. Note that this field indicates the overflow status for all counters, regardless of whether they were programmed for PEBS or not.

**Programming PEBS Facility**

Only a subset of non-architectural performance events in the processor support PEBS. The subset of precise events are listed in Table 18-10. In addition to using IA32_PERFEVTSELx to specify event unit/mask settings and setting the EN_PMCx bit in the IA32_PEBS_ENABLE register for the respective counter, the software must also initialize the DS_BUFFER_MANAGEMENT_AREA data structure in memory to support capturing PEBS records for precise events.

NOTE

PEBS events are only valid when the following fields of IA32_PERFEVTSELx are all zero: AnyThread, Edge, Invert, CMask.

The beginning linear address of the DS_BUFFER_MANAGEMENT_AREA data structure must be programmed into the IA32_DS_AREA register. The layout of the DS_BUFFER_MANAGEMENT_AREA is shown in Figure 18-18.

- **PEBS Buffer Base**: This field is programmed with the linear address of the first byte of the PEBS buffer allocated by software. The processor reads this field to determine the base address of the PEBS buffer. Software should allocate this memory from the non-paged pool.

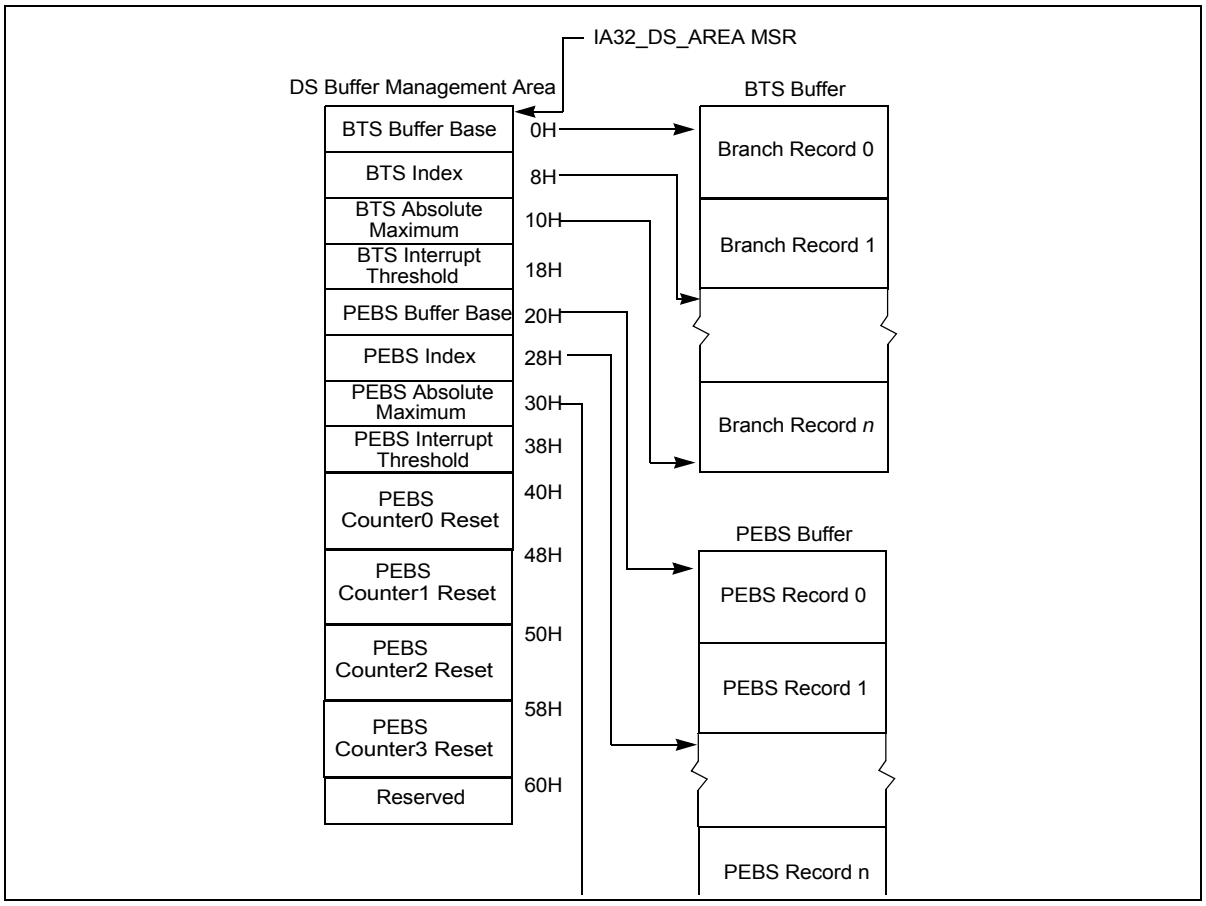

Figure 18-18. PEBS Programming Environment

- **PEBS Index**: This field is initially programmed with the same value as the PEBS Buffer Base field, or the beginning linear address of the PEBS buffer. The processor reads this field to determine the location of the next PEBS record to write to. After a PEBS record has been written, the processor also updates this field with the address of the next PEBS record to be written. The figure above illustrates the state of PEBS Index after the first PEBS record is written.
- **PEBS Absolute Maximum**: This field represents the absolute address of the maximum length of the allocated PEBS buffer plus the starting address of the PEBS buffer. The processor will not write any PEBS record beyond the end of PEBS buffer, when **PEBS Index** equals **PEBS Absolute Maximum**. No signaling is generated when PEBS buffer is full. Software must reset the **PEBS Index** field to the beginning of the PEBS buffer address to continue capturing PEBS records.
- **PEBS Interrupt Threshold**: This field specifies the threshold value to trigger a performance interrupt and notify software that the PEBS buffer is nearly full. This field is programmed with the linear address of the first byte of the PEBS record within the PEBS buffer that represents the threshold record. After the processor writes a PEBS record and updates **PEBS Index**, if the **PEBS Index** reaches the threshold value of this field, the processor will generate a performance interrupt. This is the same interrupt that is generated by a performance counter overflow, as programmed in the Performance Monitoring Counters vector in the Local Vector Table of the Local APIC. When a performance interrupt due to PEBS buffer full is generated, the IA32_PERF_GLOBAL_STATUS.PEBS_Ovf bit will be set.
- **PEBS CounterX Reset**: This field allows software to set up PEBS counter overflow condition to occur at a rate useful for profiling workload, thereby generating multiple PEBS records to facilitate characterizing the profile the execution of test code. After each PEBS record is written, the processor checks each counter to see if it overflowed and was enabled for PEBS (the corresponding bit in IA32_PEBS_ENABLED was set). If these conditions are met, then the reset value for each overflowed counter is loaded from the DS Buffer Management

Area. For example, if counter IA32_PMC0 caused a PEBS record to be written, then the value of "PEBS Counter 0 Reset" would be written to counter IA32_PMC0. If a counter is not enabled for PEBS, its value will not be modified by the PEBS assist.

**Performance Counter Prioritization**

Performance monitoring interrupts are triggered by a counter transitioning from maximum count to zero (assuming IA32_PerfEvtSelX.INT is set). This same transition will cause PEBS hardware to arm, but not trigger. PEBS hardware triggers upon detection of the first PEBS event after the PEBS hardware has been armed (a 0 to 1 transition of the counter). At this point, a PEBS assist will be undertaken by the processor.

Performance counters (fixed and general-purpose) are prioritized in index order. That is, counter IA32_PMC0 takes precedence over all other counters. Counter IA32_PMC1 takes precedence over counters IA32_PMC2 and IA32_PMC3, and so on. This means that if simultaneous overflows or PEBS assists occur, the appropriate action will be taken for the highest priority performance counter. For example, if IA32_PMC1 cause an overflow interrupt and IA32_PMC2 causes an PEBS assist simultaneously, then the overflow interrupt will be serviced first.

The PEBS threshold interrupt is triggered by the PEBS assist, and is by definition prioritized lower than the PEBS assist. Hardware will not generate separate interrupts for each counter that simultaneously overflows. General-purpose performance counters are prioritized over fixed counters.

If a counter is programmed with a precise (PEBS-enabled) event and programmed to generate a counter overflow interrupt, the PEBS assist is serviced before the counter overflow interrupt is serviced. If in addition the PEBS interrupt threshold is met, the

threshold interrupt is generated after the PEBS assist completes, followed by the counter overflow interrupt (two separate interrupts are generated).

Uncore counters may be programmed to interrupt one or more processor cores (see Section 18.7.2). It is possible for interrupts posted from the uncore facility to occur coincident with counter overflow interrupts from the processor core. Software must check core and uncore status registers to determine the exact origin of counter overflow interrupts.

#### 18.7.1.2 Load Latency Performance Monitoring Facility

The load latency facility provides software a means to characterize the average load latency to different levels of cache/memory hierarchy. This facility requires processor supporting enhanced PEBS record format in the PEBS buffer, see Table 18-18. This field measures the load latency from load's first dispatch of till final data writeback from the memory subsystem. The latency is reported for retired demand load operations and in core cycles (it accounts for re-dispatches).

To use this feature software must assure:

- One of the IA32_PERFEVTSELx MSR is programmed to specify the event unit MEM_INST_RETIRED, and the LATENCY_ABOVE_THRESHOLD event mask must be specified (IA32_PerfEvtSelX[15:0] = 100H). The corresponding counter IA32_PMCx will accumulate event counts for architecturally visible loads which exceed the programmed latency threshold specified separately in a MSR. Stores are ignored when this event is programmed. The CMASK or INV fields of the IA32_PerfEvtSelX register used for counting load latency must be 0. Writing other values will result in undefined behavior.
- The MSR_PEBS_LD_LAT_THRESHOLD MSR is programmed with the desired latency threshold in core clock cycles. Loads with latencies greater than this value are eligible for counting and latency data reporting. The minimum value that may be programmed in this register is 3 (the minimum detectable load latency is 4 core clock cycles).
- The PEBS enable bit in the IA32_PEBS_ENABLE register is set for the corresponding IA32_PMCx counter register. This means that both the PEBS_EN_CTRX and LL_EN_CTRX bits must be set for the counter(s) of interest. For example, to enable load latency on counter IA32_PMC0, the IA32_PEBS_ENABLE register must be programmed with the 64-bit value 00000001_00000001H.

When the load-latency facility is enabled, load operations are randomly selected by hardware and tagged to carry information related to data source locality and latency. Latency and data source information of tagged loads are updated internally.

When a PEBS assist occurs, the last update of latency and data source information are captured by the assist and written as part of the PEBS record. The PEBS sample after value (SAV), specified in PEBS CounterX Reset, operates

orthogonally to the tagging mechanism. Loads are randomly tagged to collect latency data. The SAV controls the number of tagged loads with latency information that will be written into the PEBS record field by the PEBS assists. The load latency data written to the PEBS record will be for the last tagged load operation which retired just before the PEBS assist was invoked.

The load-latency information written into a PEBS record (see Table 18-18, bytes AFH:98H) consists of:

- **Data Linear Address**: This is the linear address of the target of the load operation.
- **Latency Value**: This is the elapsed cycles of the tagged load operation between dispatch to GO, measured in processor core clock domain.
- **Data Source:** The encoded value indicates the origin of the data obtained by the load instruction. The encoding is shown in Table 18-19. In the descriptions local memory refers to system memory physically attached to a processor package, and remote memory referrals to system memory physically attached to another processor package.

**Table 18-19. Data Source Encoding for Load Latency Record**

| Encoding | Description |
|---|---|
| 00H | Unknown L3 cache miss |
| 01H | Minimal latency core cache hit. This request was satisfied by the L1 data cache. |
| 02H | Pending core cache HIT. Outstanding core cache miss to same cache-line address was already underway. |
| 03H | This data request was satisfied by the L2. |
| 04H | L3 HIT. Local or Remote home requests that hit L3 cache in the uncore with no coherency actions required (snooping). |
| 05H | L3 HIT. Local or Remote home requests that hit the L3 cache and was serviced by another processor core with a cross core snoop where no modified copies were found. (clean). |
| 06H | L3 HIT. Local or Remote home requests that hit the L3 cache and was serviced by another processor core with a cross core snoop where modified copies were found. (HITM). |
| 07H[1] | Reserved/LLC Snoop HitM. Local or Remote home requests that hit the last level cache and was serviced by another core with a cross core snoop where modified copies found |
| 08H | L3 MISS. Local homed requests that missed the L3 cache and was serviced by forwarded data following a cross package snoop where no modified copies found. (Remote home requests are not counted). |
| 09H | Reserved |
| 0AH | L3 MISS. Local home requests that missed the L3 cache and was serviced by local DRAM (go to shared state). |
| 0BH | L3 MISS. Remote home requests that missed the L3 cache and was serviced by remote DRAM (go to shared state). |
| 0CH | L3 MISS. Local home requests that missed the L3 cache and was serviced by local DRAM (go to exclusive state). |
| 0DH | L3 MISS. Remote home requests that missed the L3 cache and was serviced by remote DRAM (go to exclusive state). |
| 0EH | I/O, Request of input/output operation |
| 0FH | The request was to un-cacheable memory. |

**NOTES:**

1. Bit 7 is supported only for processor with CPUID DisplayFamily_DisplayModel signature of 06_2A, and 06_2E; otherwise it is reserved.

The layout of MSR_PEBS_LD_LAT_THRESHOLD is shown in Figure 18-19.

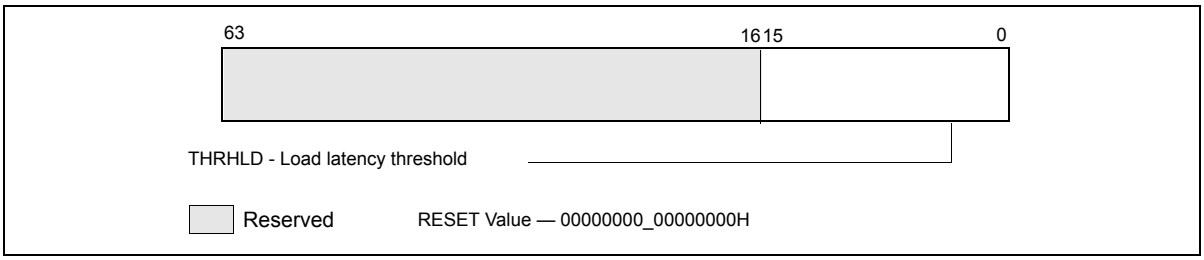

Figure 18-19. Layout of MSR_PEBS_LD_LAT MSR

Bits 15:0 specifies the threshold load latency in core clock cycles. Performance events with latencies greater than this value are counted in IA32_PMCx and their latency information is reported in the PEBS record. Otherwise, they are ignored. The minimum value that may be programmed in this field is 3.

### 18.7.1.3 Off-core Response Performance Monitoring in the Processor Core

Programming a performance event using the off-core response facility can choose any of the four IA32_PERFEVTSELx MSR with specific event codes and predefine mask bit value. Each event code for off-core response monitoring requires programming an associated configuration MSR, MSR_OFFCORE_RSP_0. There is only one off-core response configuration MSR. Table 18-20 lists the event code, mask value and additional off-core configuration MSR that must be programmed to count off-core response events using IA32_PMCx.

Table 18-20. Off-Core Response Event Encoding

| **Event code in** IA32_PERFEVTSELx | **Mask Value in** IA32_PERFEVTSELx | **Required Off-core Response MSR** |
|---|---|---|
| B7H | 01H | MSR_OFFCORE_RSP_0 (address 1A6H) |

The layout of MSR_OFFCORE_RSP_0 is shown in Figure 18-20. Bits 7:0 specifies the request type of a transaction request to the uncore. Bits 15:8 specifies the response of the uncore subsystem.

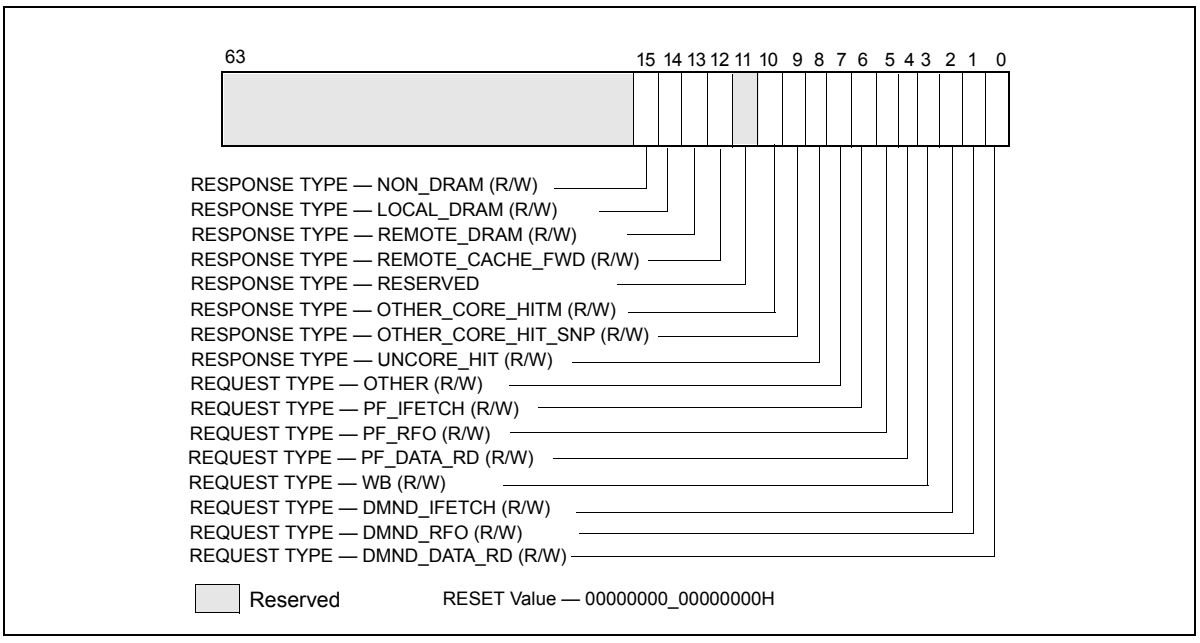

Figure 18-20. Layout of MSR_OFFCORE_RSP_0 and MSR_OFFCORE_RSP_1 to Configure Off-core Response Events

Table 18-21. MSR_OFFCORE_RSP_0 and MSR_OFFCORE_RSP_1 Bit Field Definition

| Bit Name | Offset | Description |
|---|---|---|
| DMND_DATA_RD | 0 | (R/W). Counts the number of demand and DCU prefetch data reads of full and partial cachelines as well as demand data page table entry cacheline reads. Does not count L2 data read prefetches or instruction fetches. |
| DMND_RFO | 1 | (R/W). Counts the number of demand and DCU prefetch reads for ownership (RFO) requests generated by a write to data cacheline. Does not count L2 RFO. |
| DMND_IFETCH | 2 | (R/W). Counts the number of demand and DCU prefetch instruction cacheline reads. Does not count L2 code read prefetches. |
| WB | 3 | (R/W). Counts the number of writeback (modified to exclusive) transactions. |
| PF_DATA_RD | 4 | (R/W). Counts the number of data cacheline reads generated by L2 prefetchers. |
| PF_RFO | 5 | (R/W). Counts the number of RFO requests generated by L2 prefetchers. |
| PF_IFETCH | 6 | (R/W). Counts the number of code reads generated by L2 prefetchers. |
| OTHER | 7 | (R/W). Counts one of the following transaction types, including L3 invalidate, I/O, full or partial writes, WC or non-temporal stores, CLFLUSH, Fences, lock, unlock, split lock. |
| UNCORE_HIT | 8 | (R/W). L3 Hit: local or remote home requests that hit L3 cache in the uncore with no coherency actions required (snooping). |
| OTHER_CORE_HIT_SNP | 9 | (R/W). L3 Hit: local or remote home requests that hit L3 cache in the uncore and was serviced by another core with a cross core snoop where no modified copies were found (clean). |
| OTHER_CORE_HITM | 10 | (R/W). L3 Hit: local or remote home requests that hit L3 cache in the uncore and was serviced by another core with a cross core snoop where modified copies were found (HITM). |
| Reserved | 11 | Reserved |
| REMOTE_CACHE_FWD | 12 | (R/W). L3 Miss: local homed requests that missed the L3 cache and was serviced by forwarded data following a cross package snoop where no modified copies found. (Remote home requests are not counted) |
| REMOTE_DRAM | 13 | (R/W). L3 Miss: remote home requests that missed the L3 cache and were serviced by remote DRAM. |
| LOCAL_DRAM | 14 | (R/W). L3 Miss: local home requests that missed the L3 cache and were serviced by local DRAM. |
| NON_DRAM | 15 | (R/W). Non-DRAM requests that were serviced by IOH. |

## 18.7.2 Performance Monitoring Facility in the Uncore

The "uncore" in Intel microarchitecture code name Nehalem refers to subsystems in the physical processor package that are shared by multiple processor cores. Some of the sub-systems in the uncore include the L3 cache, Intel QuickPath Interconnect link logic, and integrated memory controller. The performance monitoring facilities inside the uncore operates in the same clock domain as the uncore (U-clock domain), which is usually different from the processor core clock domain. The uncore performance monitoring facilities described in this section apply to Intel Xeon processor 5500 series and processors with the following CPUID signatures: 06_1AH, 06_1EH, 06_1FH (see Chapter 35). An overview of the uncore performance monitoring facilities is described separately.

The performance monitoring facilities available in the U-clock domain consist of:

- Eight General-purpose counters (MSR_UNCORE_PerfCntr0 through MSR_UNCORE_PerfCntr7). The counters are 48 bits wide. Each counter is associated with a configuration MSR, MSR_UNCORE_PerfEvtSelx, to specify event code, event mask and other event qualification fields. A set of global uncore performance counter enabling/overflow/status control MSRs are also provided for software.
- Performance monitoring in the uncore provides an address/opcode match MSR that provides event qualification control based on address value or QPI command opcode.
- One fixed-function counter, MSR_UNCORE_FixedCntr0. The fixed-function uncore counter increments at the rate of the U-clock when enabled.

The frequency of the uncore clock domain can be determined from the uncore clock ratio which is available in the PCI configuration space register at offset C0H under device number 0 and Function 0.

### 18.7.2.1 Uncore Performance Monitoring Management Facility

MSR_UNCORE_PERF_GLOBAL_CTRL provides bit fields to enable/disable general-purpose and fixed-function counters in the uncore. Figure 18-21 shows the layout of MSR_UNCORE_PERF_GLOBAL_CTRL for an uncore that is shared by four processor cores in a physical package.

- EN_PCn (bit n, n = 0, 7): When set, enables counting for the general-purpose uncore counter MSR_UNCORE_PerfCntr n.
- EN_FC0 (bit 32): When set, enables counting for the fixed-function uncore counter MSR_UNCORE_FixedCntr0.
- EN_PMI_COREn (bit n, n = 0, 3 if four cores are present): When set, processor core n is programmed to receive an interrupt signal from any interrupt enabled uncore counter. PMI delivery due to an uncore counter overflow is enabled by setting IA32_DEBUG_CTL.Offcore_PMI_EN to 1.
- PMI_FRZ (bit 63): When set, all U-clock uncore counters are disabled when any one of them signals a performance interrupt. Software must explicitly re-enable the counter by setting the enable bits in MSR_UNCORE_PERF_GLOBAL_CTRL upon exit from the ISR.

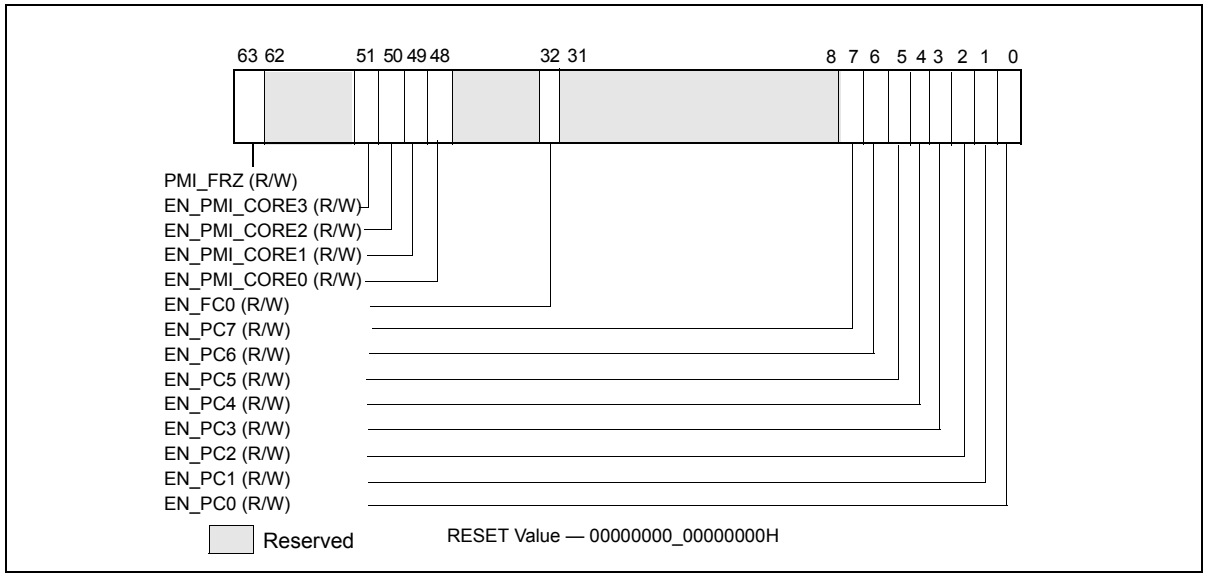

**Figure 18-21. Layout of MSR_UNCORE_PERF_GLOBAL_CTRL MSR**

MSR_UNCORE_PERF_GLOBAL_STATUS provides overflow status of the U-clock performance counters in the uncore. This is a read-only register. If an overflow status bit is set the corresponding counter has overflowed. The register provides a condition change bit (bit 63) which can be quickly checked by software to determine if a significant change has occurred since the last time the condition change status was cleared. Figure 18-22 shows the layout of MSR_UNCORE_PERF_GLOBAL_STATUS.

- OVF_PCn (bit n, n = 0, 7): When set, indicates general-purpose uncore counter MSR_UNCORE_PerfCntr n has overflowed.
- OVF_FC0 (bit 32): When set, indicates the fixed-function uncore counter MSR_UNCORE_FixedCntr0 has overflowed.
- OVF_PMI (bit 61): When set indicates that an uncore counter overflowed and generated an interrupt request.
- CHG (bit 63): When set indicates that at least one status bit in MSR_UNCORE_PERF_GLOBAL_STATUS register has changed state.

MSR_UNCORE_PERF_GLOBAL_OVF_CTRL allows software to clear the status bits in the UNCORE_PERF_GLOBAL_STATUS register. This is a write-only register, and individual status bits in the global

status register are cleared by writing a binary one to the corresponding bit in this register. Writing zero to any bit position in this register has no effect on the uncore PMU hardware.

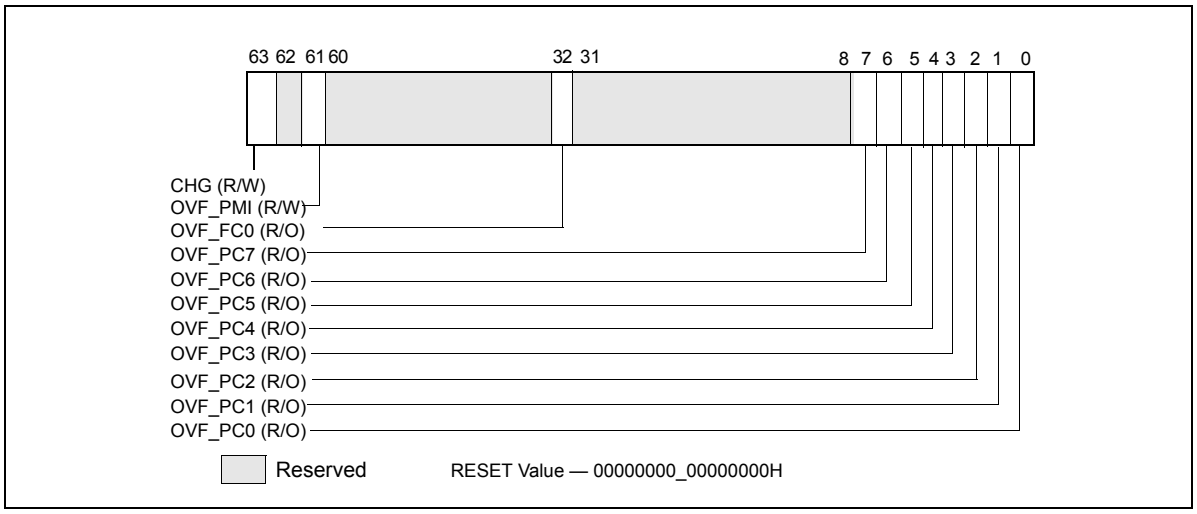

**Figure 18-22. Layout of MSR_UNCORE_PERF_GLOBAL_STATUS MSR**

Figure 18-23 shows the layout of MSR_UNCORE_PERF_GLOBAL_OVF_CTRL.

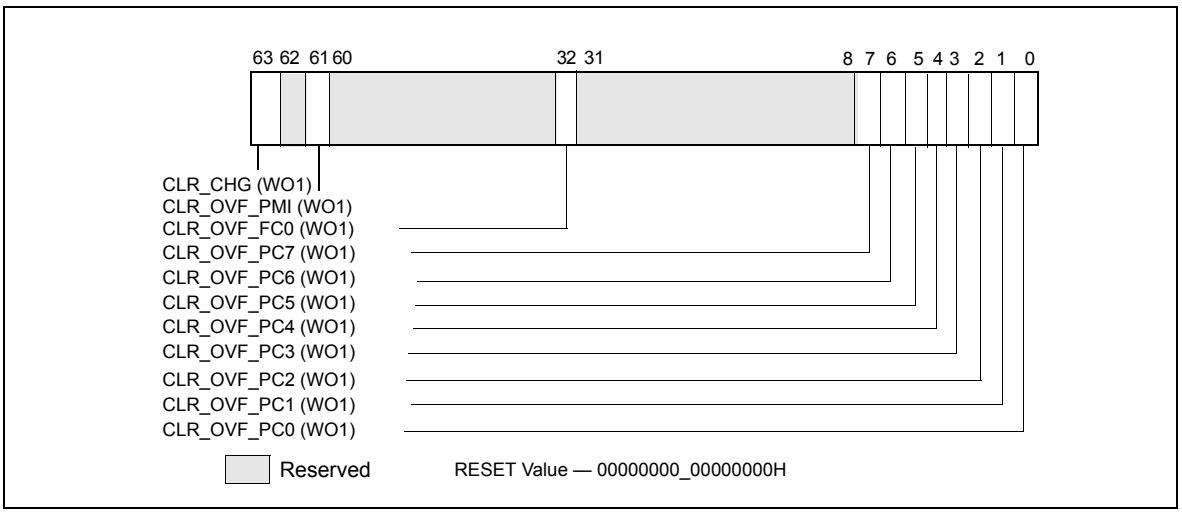

**Figure 18-23. Layout of MSR_UNCORE_PERF_GLOBAL_OVF_CTRL MSR**

- CLR_OVF_PCn (bit n, n = 0, 7): Set this bit to clear the overflow status for general-purpose uncore counter MSR_UNCORE_PerfCntr n. Writing a value other than 1 is ignored.
- CLR_OVF_FC0 (bit 32): Set this bit to clear the overflow status for the fixed-function uncore counter MSR_UNCORE_FixedCntr0. Writing a value other than 1 is ignored.
- CLR_OVF_PMI (bit 61): Set this bit to clear the OVF_PMI flag in MSR_UNCORE_PERF_GLOBAL_STATUS. Writing a value other than 1 is ignored.
- CLR_CHG (bit 63): Set this bit to clear the CHG flag in MSR_UNCORE_PERF_GLOBAL_STATUS register. Writing a value other than 1 is ignored.

### 18.7.2.2 Uncore Performance Event Configuration Facility

MSR_UNCORE_PerfEvtSel0 through MSR_UNCORE_PerfEvtSel7 are used to select performance event and configure the counting behavior of the respective uncore performance counter. Each uncore PerfEvtSel MSR is paired with an uncore performance counter. Each uncore counter must be locally configured using the corresponding MSR_UNCORE_PerfEvtSelx and counting must be enabled using the respective EN_PCx bit in MSR_UNCORE_PERF_GLOBAL_CTRL. Figure 18-24 shows the layout of MSR_UNCORE_PERFEVTSELx.

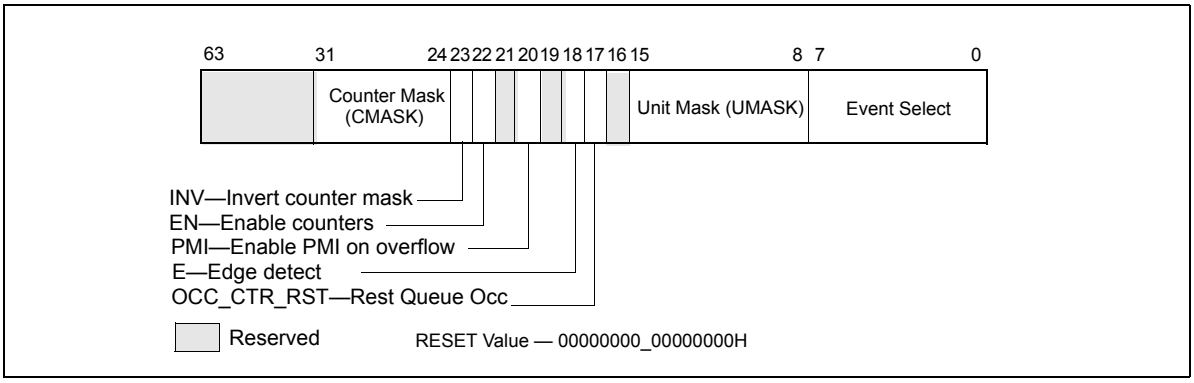

**Figure 18-24. Layout of MSR_UNCORE_PERFEVTSELx MSRs**

- Event Select (bits 7:0): Selects the event logic unit used to detect uncore events.
- Unit Mask (bits 15:8) : Condition qualifiers for the event selection logic specified in the Event Select field.
- OCC_CTR_RST (bit17): When set causes the queue occupancy counter associated with this event to be cleared (zeroed). Writing a zero to this bit will be ignored. It will always read as a zero.
- Edge Detect (bit 18): When set causes the counter to increment when a deasserted to asserted transition occurs for the conditions that can be expressed by any of the fields in this register.
- PMI (bit 20): When set, the uncore will generate an interrupt request when this counter overflowed. This request will be routed to the logical processors as enabled in the PMI enable bits (EN_PMI_COREx) in the register MSR_UNCORE_PERF_GLOBAL_CTRL.
- EN (bit 22): When clear, this counter is locally disabled. When set, this counter is locally enabled and counting starts when the corresponding EN_PCx bit in MSR_UNCORE_PERF_GLOBAL_CTRL is set.
- INV (bit 23): When clear, the Counter Mask field is interpreted as greater than or equal to. When set, the Counter Mask field is interpreted as less than.
- Counter Mask (bits 31:24): When this field is clear, it has no effect on counting. When set to a value other than zero, the logical processor compares this field to the event counts on each core clock cycle. If INV is clear and the event counts are greater than or equal to this field, the counter is incremented by one. If INV is set and the event counts are less than this field, the counter is incremented by one. Otherwise the counter is not incremented.

Figure 18-25 shows the layout of MSR_UNCORE_FIXED_CTR_CTRL.

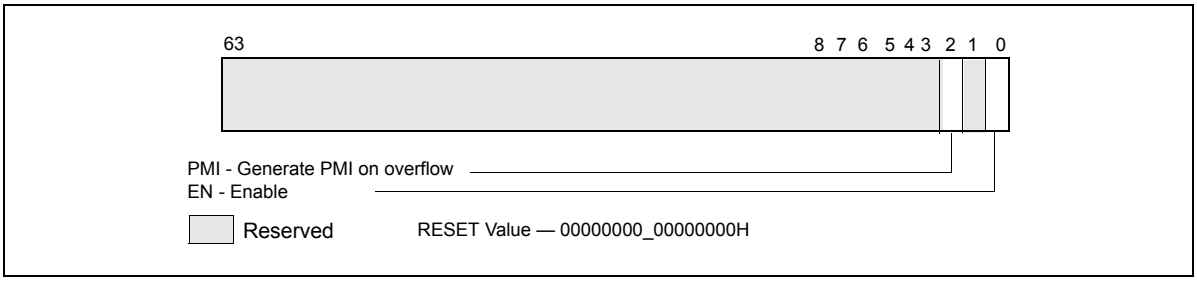

**Figure 18-25. Layout of MSR_UNCORE_FIXED_CTR_CTRL MSR**

- EN (bit 0): When clear, the uncore fixed-function counter is locally disabled. When set, it is locally enabled and counting starts when the EN_FC0 bit in MSR_UNCORE_PERF_GLOBAL_CTRL is set.
- PMI (bit 2): When set, the uncore will generate an interrupt request when the uncore fixed-function counter overflowed. This request will be routed to the logical processors as enabled in the PMI enable bits (EN_PMI_COREx) in the register MSR_UNCORE_PERF_GLOBAL_CTRL.

Both the general-purpose counters (MSR_UNCORE_PerfCntr) and the fixed-function counter (MSR_UNCORE_FixedCntr0) are 48 bits wide. They support both counting and sampling usages. The event logic unit can filter event counts to specific regions of code or transaction types incoming to the home node logic.

### 18.7.2.3 Uncore Address/Opcode Match MSR

The Event Select field [7:0] of MSR_UNCORE_PERFEVTSELx is used to select different uncore event logic unit. When the event "ADDR_OPCODE_MATCH" is selected in the Event Select field, software can filter uncore performance events according to transaction address and certain transaction responses. The address filter and transaction response filtering requires the use of MSR_UNCORE_ADDR_OPCODE_MATCH register. The layout is shown in Figure 18-26.

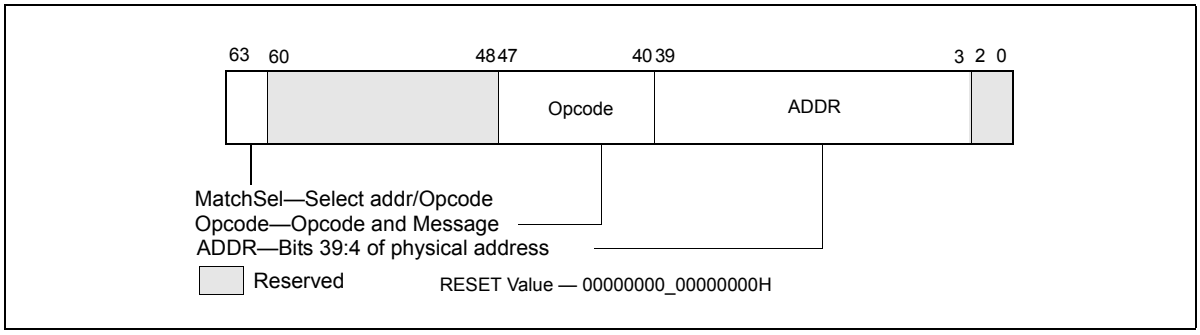

Figure 18-26. Layout of MSR_UNCORE_ADDR_OPCODE_MATCH MSR

- Addr (bits 39:3): The physical address to match if "MatchSel" field is set to select address match. The uncore performance counter will increment if the lowest 40-bit incoming physical address (excluding bits 2:0) for a transaction request matches bits 39:3.
- Opcode (bits 47:40) : Bits 47:40 allow software to filter uncore transactions based on QPI link message class/packed header opcode. These bits are consists two sub-fields:
  - — Bits 43:40 specify the QPI packet header opcode,
  - — Bits 47:44 specify the QPI message classes.

  Table 18-22 lists the encodings supported in the opcode field.

Table 18-22. Opcode Field Encoding for MSR_UNCORE_ADDR_OPCODE_MATCH

| **Opcode [43:40]** | QPI Message Class | | |
|---|---|---|---|
| | Home Request<br>[47:44] = 0000B | Snoop Response<br>[47:44] = 0001B | Data Response<br>[47:44] = 1110B |
| | | 1 | |
| DMND_IFETCH | 2 | 2 | |
| WB | 3 | 3 | |
| PF_DATA_RD | 4 | 4 | |
| PF_RFO | 5 | 5 | |
| PF_IFETCH | 6 | 6 | |

Table 18-22. Opcode Field Encoding for MSR_UNCORE_ADDR_OPCODE_MATCH (Contd.)

| Opcode [43:40] | QPI Message Class | | |
|---|---|---|---|
| OTHER | 7 | 7 | |
| NON_DRAM | 15 | 15 | |

- MatchSel (bits 63:61): Software specifies the match criteria according to the following encoding:
  - 000B: Disable addr_opcode match hardware
  - 100B: Count if only the address field matches,
  - 010B: Count if only the opcode field matches
  - 110B: Count if either opcode field matches or the address field matches
  - 001B: Count only if both opcode and address field match
  - Other encoding are reserved

## 18.7.3 Intel® Xeon® Processor 7500 Series Performance Monitoring Facility

The performance monitoring facility in the processor core of Intel® Xeon® processor 7500 series are the same as those supported in Intel Xeon processor 5500 series. The uncore subsystem in Intel Xeon processor 7500 series are significantly different The uncore performance monitoring facility consist of many distributed units associated with individual logic control units (referred to as boxes) within the uncore subsystem. A high level block diagram of the various box units of the uncore is shown in Figure 18-27.

Uncore PMUs are programmed via MSR interfaces. Each of the distributed uncore PMU units have several general-purpose counters. Each counter requires an associated event select MSR, and may require additional MSRs to configure sub-event conditions. The uncore PMU MSRs associated with each box can be categorized based on its functional scope: per-counter, per-box, or global across the uncore. The number counters available in each box type are different. Each box generally provides a set of MSRs to enable/disable, check status/overflow of multiple counters within each box.

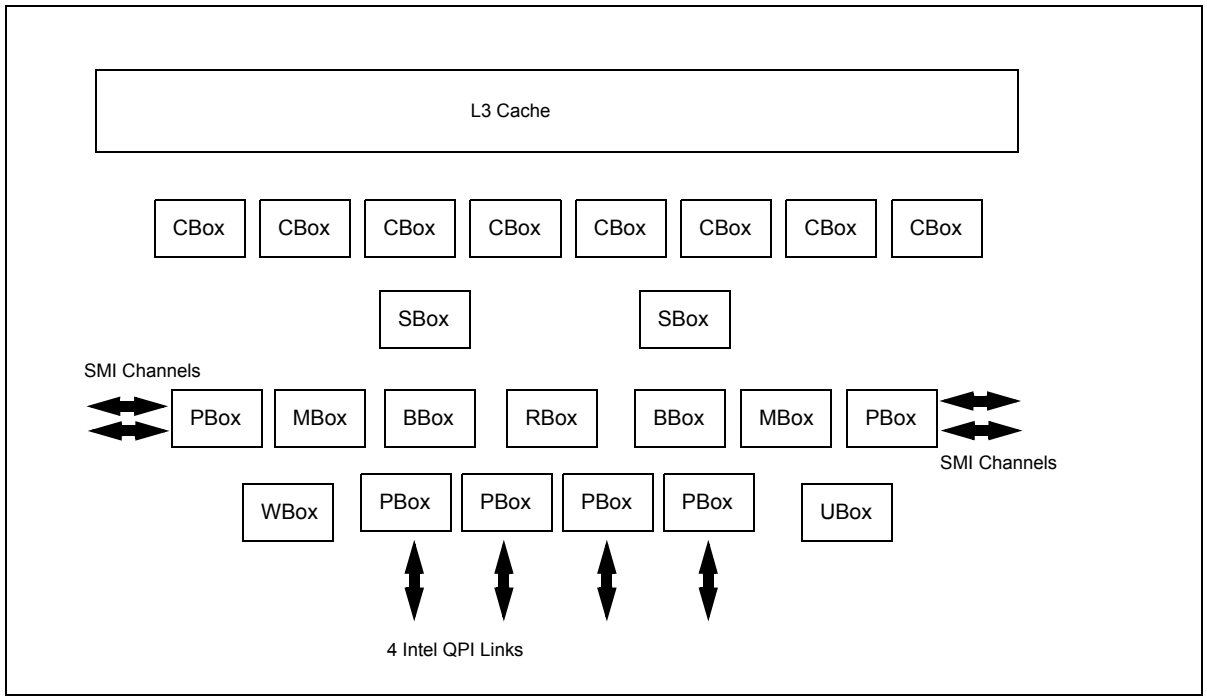

Figure 18-27. Distributed Units of the Uncore of Intel® Xeon® Processor 7500 Series

Table 18-23 summarizes the number MSRs for uncore PMU for each box.

**Table 18-23. Uncore PMU MSR Summary**

| Box | # of Boxes | Counters per Box | Counter Width | General Purpose | Global Enable | Sub-control MSRs |
|---|---|---|---|---|---|---|
| C-Box | 8 | 6 | 48 | Yes | per-box | None |
| S-Box | 2 | 4 | 48 | Yes | per-box | Match/Mask |
| B-Box | 2 | 4 | 48 | Yes | per-box | Match/Mask |
| M-Box | 2 | 6 | 48 | Yes | per-box | Yes |
| R-Box | 1 | 16 ( 2 port, 8 per port) | 48 | Yes | per-box | Yes |
| W-Box | 1 | 4 | 48 | Yes | per-box | None |
| | | 1 | 48 | No | per-box | None |
| U-Box | 1 | 1 | 48 | Yes | uncore | None |

The W-Box provides 4 general-purpose counters, each requiring an event select configuration MSR, similar to the general-purpose counters in other boxes. There is also a fixed-function counter that increments clockticks in the uncore clock domain.

For C,S,B,M,R, and W boxes, each box provides an MSR to enable/disable counting, configuring PMI of multiple counters within the same box, this is somewhat similar the "global control" programming interface, IA32_PERF_GLOBAL_CTRL, offered in the core PMU. Similarly status information and counter overflow control for multiple counters within the same box are also provided in C,S,B,M,R, and W boxes.

In the U-Box, MSR_U_PMON_GLOBAL_CTL provides overall uncore PMU enable/disable and PMI configuration control. The scope of status information in the U-box is at per-box granularity, in contrast to the per-box status information MSR (in the C,S,B,M,R, and W boxes) providing status information of individual counter overflow. The difference in scope also apply to the overflow control MSR in the U-Box versus those in the other Boxes.

The individual MSRs that provide uncore PMU interfaces are listed in Chapter 35, Table 35-12 under the general naming style of MSR_%box#%_PMON_%scope_function%, where %box#% designates the type of box and zero-based index if there are more the one box of the same type, %scope_function% follows the examples below:

- Multi-counter enabling MSRs: MSR_U_PMON_GLOBAL_CTL, MSR_S0_PMON_BOX_CTL, MSR_C7_PMON_BOX_CTL, etc.
- Multi-counter status MSRs: MSR_U_PMON_GLOBAL_STATUS, MSR_S0_PMON_BOX_STATUS, MSR_C7_PMON_BOX_STATUS, etc.
- Multi-counter overflow control MSRs: MSR_U_PMON_GLOBAL_OVF_CTL, MSR_S0_PMON_BOX_OVF_CTL, MSR_C7_PMON_BOX_OVF_CTL, etc.
- Performance counters MSRs: the scope is implicitly per counter, e.g. MSR_U_PMON_CTR, MSR_S0_PMON_CTR0, MSR_C7_PMON_CTR5, etc.
- Event select MSRs: the scope is implicitly per counter, e.g. MSR_U_PMON_EVNT_SEL, MSR_S0_PMON_EVNT_SEL0, MSR_C7_PMON_EVNT_SEL5, etc
- Sub-control MSRs: the scope is implicitly per-box granularity, e.g. MSR_M0_PMON_TIMESTAMP, MSR_R0_PMON_IPERF0_P1, MSR_S1_PMON_MATCH.

Details of uncore PMU MSR bit field definitions can be found in a separate document "Intel Xeon Processor 7500 Series Uncore Performance Monitoring Guide".

## 18.8 PERFORMANCE MONITORING FOR PROCESSORS BASED ON INTEL® MICROARCHITECTURE CODE NAME WESTMERE

All of the performance monitoring programming interfaces (architectural and non-architectural core PMU facilities, and uncore PMU) described in Section 18.7 also apply to processors based on Intel® microarchitecture code name Westmere.

Table 18-20 describes a non-architectural performance monitoring event (event code 0B7H) and associated MSR_OFFCORE_RSP_0 (address 1A6H) in the core PMU. This event and a second functionally equivalent offcore response event using event code 0BBH and MSR_OFFCORE_RSP_1 (address 1A7H) are supported in processors based on Intel microarchitecture code name Westmere. The event code and event mask definitions of Non-architectural performance monitoring events are listed in Table 19-21.

The load latency facility is the same as described in Section 18.7.1.2, but added enhancement to provide more information in the data source encoding field of each load latency record. The additional information relates to STLB_MISS and LOCK, see Table 18-28.

### 18.8.1 Intel® Xeon® Processor E7 Family Performance Monitoring Facility

The performance monitoring facility in the processor core of the Intel® Xeon® processor E7 family is the same as those supported in the Intel Xeon processor 5600 series[2]. The uncore subsystem in the Intel Xeon processor E7 family is similar to those of the Intel Xeon processor 7500 series. The high level construction of the uncore subsystem is similar to that shown in Figure 18-27, with the additional capability that up to 10 C-Box units are supported.

Table 18-24 summarizes the number MSRs for uncore PMU for each box.

**Table 18-24. Uncore PMU MSR Summary for Intel® Xeon® Processor E7 Family**

| Box | # of Boxes | Counters per Box | Counter Width | General Purpose | Global Enable | Sub-control MSRs |
|---|---|---|---|---|---|---|
| C-Box | 10 | 6 | 48 | Yes | per-box | None |
| S-Box | 2 | 4 | 48 | Yes | per-box | Match/Mask |
| B-Box | 2 | 4 | 48 | Yes | per-box | Match/Mask |
| M-Box | 2 | 6 | 48 | Yes | per-box | Yes |
| R-Box | 1 | 16 ( 2 port, 8 per port) | 48 | Yes | per-box | Yes |
| W-Box | 1 | 4 | 48 | Yes | per-box | None |
| | | 1 | 48 | No | per-box | None |
| U-Box | 1 | 1 | 48 | Yes | uncore | None |

Details of the uncore performance monitoring facility of Intel Xeon Processor E7 family is available in "Intel® Xeon® Processor E7 Uncore Performance Monitoring Programming Reference Manual".

## 18.9 PERFORMANCE MONITORING FOR PROCESSORS BASED ON INTEL® MICROARCHITECTURE CODE NAME SANDY BRIDGE

Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx processor series, and Intel® Xeon® processor E3-1200 family are based on Intel microarchitecture code name Sandy Bridge; this section describes the performance monitoring facilities provided in the processor core. The core PMU supports architectural performance monitoring capability with version ID 3 (see Section 18.2.2.2) and a host of non-architectural monitoring capabilities.

2. Exceptions are indicated for event code 0FH in Table 19-15; and valid bits of data source encoding field of each load latency record is limited to bits 5:4 of Table 18-28.

Architectural performance monitoring events and non-architectural monitoring events are programmed using fixed counters and programmable counters/event select MSRS described in Section 18.2.2.2.

The core PMU's capability is similar to those described in Section 18.7.1 and Section 18.8, with some differences and enhancements relative to Intel microarchitecture code name Westmere summarized in Table 18-25.

**Table 18-25. Core PMU Comparison**

| Box | Intel® microarchitecture code name Sandy Bridge | Intel® microarchitecture code name Westmere | Comment |
|---|---|---|---|
| # of Fixed counters per thread | 3 | 3 | Use CPUID to enumerate # of counters. |
| # of general-purpose counters per core | 8 | 8 | |
| Counter width (R,W) | R:48 , W: 32/48 | R:48, W:32 | See Section 18.2.2.3. |
| # of programmable counters per thread | 4 or (8 if a core not shared by two threads) | 4 | Use CPUID to enumerate # of counters. |
| Precise Event Based Sampling (PEBS) Events | See Table 18-27 | See Table 18-10 | IA32_PMC4-IA32_PMC7 do not support PEBS. |
| PEBS-Load Latency | See Section 18.9.4.2;<br>Data source encoding,<br>STLB miss encoding,<br>Lock transaction encoding | Data source encoding | |
| PEBS-Precise Store | Section 18.9.4.3 | No | |
| PEBS-PDIR | yes (using precise INST_RETIRED.ALL) | No | |
| Off-core Response Event | MSR 1A6H and 1A7H; Extended request and response types | MSR 1A6H and 1A7H, limited response types | Nehalem supports 1A6H only. |

## 18.9.1 Global Counter Control Facilities In Intel® Microarchitecture Code Name Sandy Bridge

The number of general-purpose performance counters visible to a logical processor can vary across Processors based on Intel microarchitecture code name Sandy Bridge. Software must use CPUID to determine the number performance counters/event select registers (See Section 18.2.1.1).

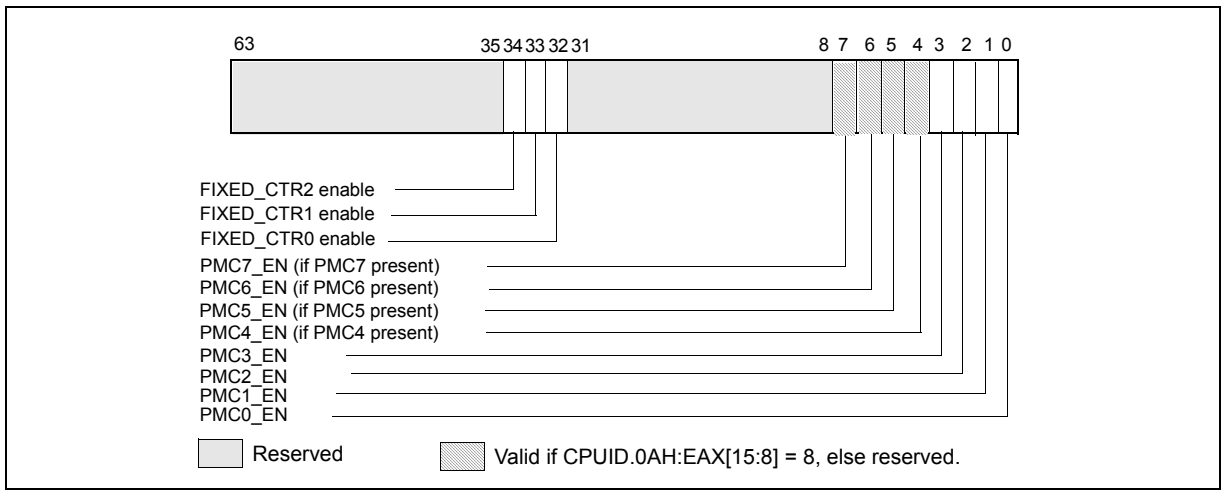

**Figure 18-28. IA32_PERF_GLOBAL_CTRL MSR in Intel® Microarchitecture Code Name Sandy Bridge**

Figure 18-11 depicts the layout of IA32_PERF_GLOBAL_CTRL MSR. The enable bits (PMC4_EN, PMC5_EN, PMC6_EN, PMC7_EN) corresponding to IA32_PMC4-IA32_PMC7 are valid only if CPUID.0AH:EAX[15:8] reports a value of '8'. If CPUID.0AH:EAX[15:8] = 4, attempts to set the invalid bits will cause #GP.

Each enable bit in IA32_PERF_GLOBAL_CTRL is AND'ed with the enable bits for all privilege levels in the respective IA32_PERFEVTSELx or IA32_PERF_FIXED_CTR_CTRL MSRs to start/stop the counting of respective counters. Counting is enabled if the AND'ed results is true; counting is disabled when the result is false.
IA32_PERF_GLOBAL_STATUS MSR provides single-bit status used by software to query the overflow condition of each performance counter. The MSR also provides additional status bit to indicate overflow conditions when counters are programmed for precise-event-based sampling (PEBS). The IA32_PERF_GLOBAL_STATUS MSR also provides a CondChgd bit to indicate changes to the state of performance monitoring hardware (see Figure 18-29). A value of 1 in each bit of the PMCx_OVF field indicates an overflow condition has occurred in the associated counter.

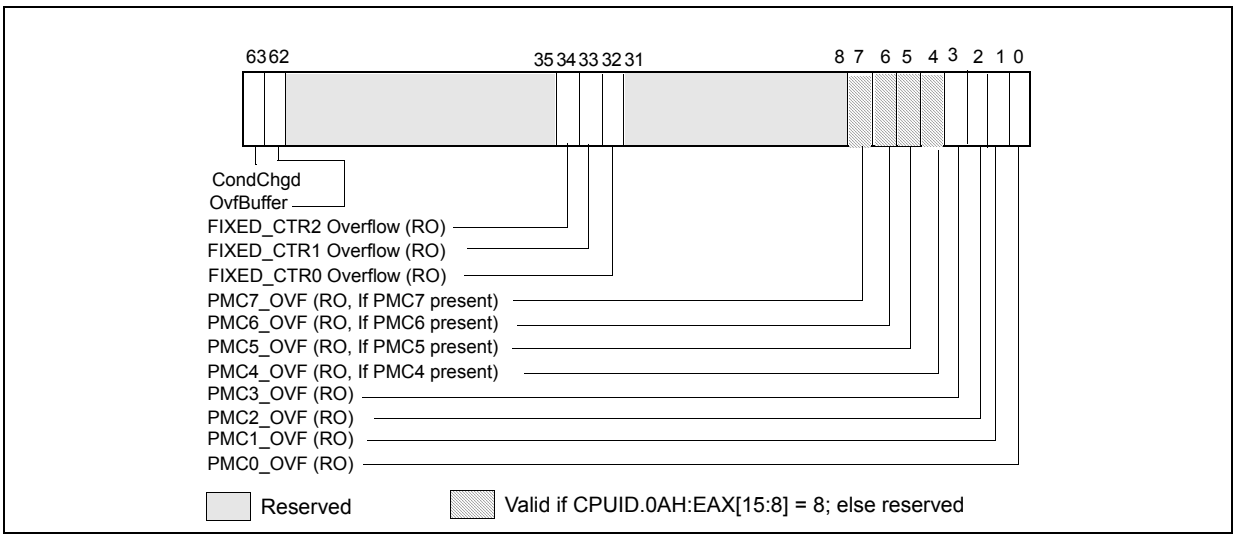

**Figure 18-29. IA32_PERF_GLOBAL_STATUS MSR in Intel® Microarchitecture Code Name Sandy Bridge**

When a performance counter is configured for PEBS, an overflow condition in the counter will arm PEBS. On the subsequent event following overflow, the processor will generate a PEBS event. On a PEBS event, the processor will perform bounds checks based on the parameters defined in the DS Save Area (see Section 17.4.9). Upon successful bounds checks, the processor will store the data record in the defined buffer area, clear the counter overflow status, and reload the counter. If the bounds checks fail, the PEBS will be skipped entirely. In the event that the PEBS buffer fills up, the processor will set the OvfBuffer bit in MSR_PERF_GLOBAL_STATUS.

IA32_PERF_GLOBAL_OVF_CTL MSR allows software to clear overflow the indicators for general-purpose or fixed-function counters via a single WRMSR (see Figure 18-30). Clear overflow indications when:

- Setting up new values in the event select and/or UMASK field for counting or sampling
- Reloading counter values to continue sampling
- Disabling event counting or sampling

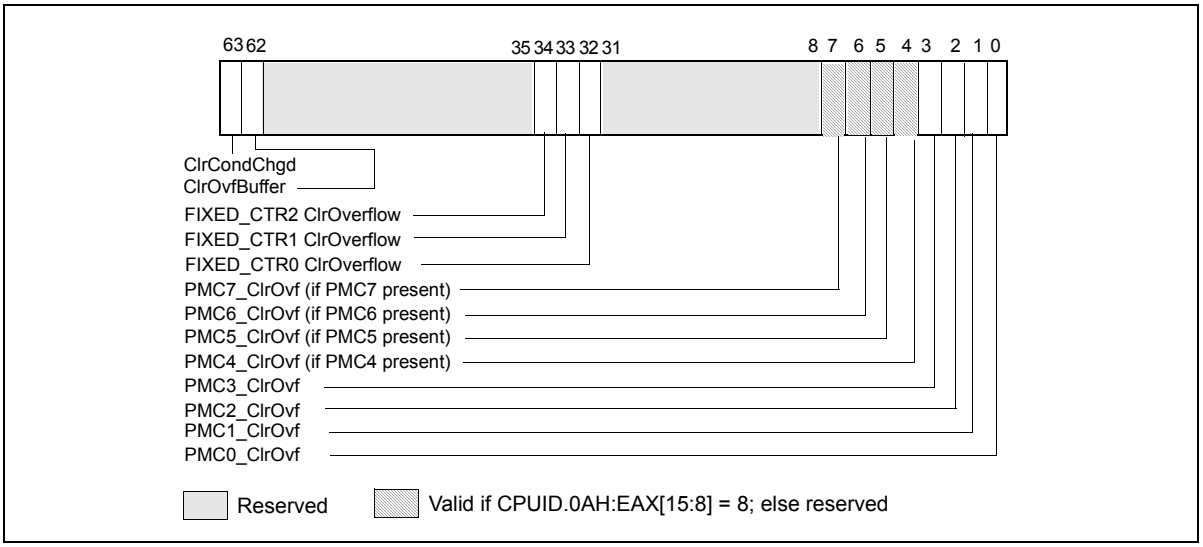

**Figure 18-30. IA32_PERF_GLOBAL_OVF_CTRL MSR in Intel microarchitecture code name Sandy Bridge**

## 18.9.2 Counter Coalescence

In processors based on Intel microarchitecture code name Sandy Bridge, each processor core implements eight general-purpose counters. CPUID.0AH:EAX[15:8] will report either 4 or 8 depending specific processor's product features.

If a processor core is shared by two logical processors, each logical processors can access 4 counters (IA32_PMC0-IA32_PMC3). This is the same as in the prior generation for processors based on Intel microarchitecture code name Nehalem.

If a processor core is not shared by two logical processors, all eight general-purpose counters are visible, and CPUID.0AH:EAX[15:8] reports 8. IA32_PMC4-IA32_PMC7 occupy MSR addresses 0C5H through 0C8H. Each counter is accompanied by an event select MSR (IA32_PERFEVTSEL4-IA32_PERFEVTSEL7).

If CPUID.0AH:EAX[15:8] report 4, access to IA32_PMC4-IA32_PMC7, IA32_PMC4-IA32_PMC7 will cause #GP. Writing 1's to bit position 7:4 of IA32_PERF_GLOBAL_CTRL, IA32_PERF_GLOBAL_STATUS, or IA32_PERF_GLOBAL_OVF_CTL will also cause #GP.

## 18.9.3 Full Width Writes to Performance Counters

Processors based on Intel microarchitecture code name Sandy Bridge support full-width writes to the general-purpose counters, IA32_PMCx. Support of full-width writes are enumerated by IA32_PERF_CAPABILITIES.FW_WRITES[13] (see Section 18.2.2.3).

The default behavior of IA32_PMCx is unchanged, i.e. WRMSR to IA32_PMCx results in a sign-extended 32-bit value of the input EAX written into IA32_PMCx. Full-width writes must issue WRMSR to a dedicated alias MSR address for each IA32_PMCx.

Software must check the presence of full-width write capability and the presence of the alias address IA32_A_PMCx by testing IA32_PERF_CAPABILITIES[13].

## 18.9.4 PEBS Support in Intel® Microarchitecture Code Name Sandy Bridge

Processors based on Intel microarchitecture code name Sandy Bridge support PEBS, similar to those offered in prior generation, with several enhanced features. The key components and differences of PEBS facility relative to Intel microarchitecture code name Westmere is summarized in Table 18-26.

**Table 18-26. PEBS Facility Comparison**

| Box | Intel® microarchitecture code name Sandy Bridge | Intel® microarchitecture code name Westmere | Comment |
|---|---|---|---|
| Valid IA32_PMCx | PMC0-PMC3 | PMC0-PMC3 | No PEBS on PMC4-PMC7 |
| PEBS Buffer Programming | Section 18.7.1.1 | Section 18.7.1.1 | Unchanged |
| IA32_PEBS_ENABLE Layout | Figure 18-31 | Figure 18-17 | |
| PEBS record layout | Physical Layout same as Table 18-18 | Table 18-18 | Enhanced fields at offsets 98H, A0H, A8H |
| PEBS Events | See Table 18-27 | See Table 18-10 | IA32_PMC4-IA32_PMC7 do not support PEBS. |
| PEBS-Load Latency | See Table 18-28 | Table 18-19 | |
| PEBS-Precise Store | yes; see Section 18.9.4.3 | No | IA32_PMC3 only |
| PEBS-PDIR | yes | No | IA32_PMC1 only |
| PEBS skid from EventingIP | 1 (or 2 if micro+macro fusion) | 1 | |
| SAMPLING Restriction | Small SAV(CountDown) value incur higher overhead than prior generation. | | |

Only IA32_PMC0 through IA32_PMC3 support PEBS.

**NOTE**

PEBS events are only valid when the following fields of IA32_PERFEVTSELx are all zero: AnyThread, Edge, Invert, CMask.

In a PMU with PDIR capability, PEBS behavior is unpredictable if IA32_PERFEVTSELx or IA32_PMCx is changed for a PEBS-enabled counter while an event is being counted. To avoid this, changes to the programming or value of a PEBS-enabled counter should be performed when the counter is disabled.

In IA32_PEBS_ENABLE MSR, bit 63 is defined as PS_ENABLE: When set, this enables IA32_PMC3 to capture precise store information. Only IA32_PMC3 supports the precise store facility. In typical usage of PEBS, the bit fields in IA32_PEBS_ENABLE are written to when the agent software starts PEBS operation; the enabled bit fields should be modified only when re-programming another PEBS event or cleared when the agent uses the performance counters for non-PEBS operations.

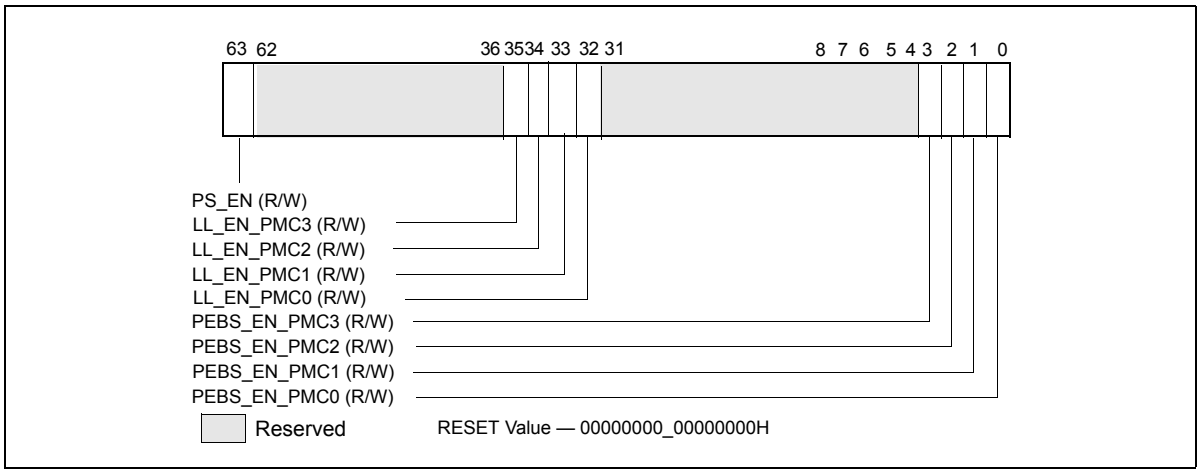

Figure 18-31. Layout of IA32_PEBS_ENABLE MSR

### 18.9.4.1 PEBS Record Format

The layout of PEBS records physically identical to those shown in Table 18-18, but the fields at offset 98H, A0H and A8H have been enhanced to support additional PEBS capabilities.

- Load/Store Data Linear Address (Offset 98H): This field will contain the linear address of the source of the load, or linear address of the destination of the store.
- Data Source /Store Status (Offset A0H):When load latency is enabled, this field will contain three piece of information (including an encoded value indicating the source which satisfied the load operation). The source field encodings are detailed in Table 18-19. When precise store is enabled, this field will contain information indicating the status of the store, as detailed in Table 19.
- Latency Value/0 (Offset A8H): When load latency is enabled, this field contains the latency in cycles to service the load. This field is not meaningful when precise store is enabled and will be written to zero in that case. Upon writing the PEBS record, microcode clears the overflow status bits in the IA32_PERF_GLOBAL_STATUS corresponding to those counters that both overflowed and were enabled in the IA32_PEBS_ENABLE register. The status bits of other counters remain unaffected.

The number PEBS events has expanded. The list of PEBS events supported in Intel microarchitecture code name Sandy Bridge is shown in Table 18-27.

Table 18-27. PEBS Performance Events for Intel® Microarchitecture Code Name Sandy Bridge

| Event Name | Event Select | Sub-event | UMask |
|---|---|---|---|
| INST_RETIRED | C0H | PREC_DIST | 01H[1] |
| UOPS_RETIRED | C2H | All | 01H |
| | | Retire_Slots | 02H |
| BR_INST_RETIRED | C4H | Conditional | 01H |
| | | Near_Call | 02H |
| | | All_branches | 04H |
| | | Near_Return | 08H |
| | | Near_Taken | 20H |

**Table 18-27. PEBS Performance Events for Intel® Microarchitecture Code Name Sandy Bridge (Contd.)**

| Event Name | Event Select | Sub-event | UMask |
|---|---|---|---|
| BR_MISP_RETIRED | C5H | Conditional | 01H |
| | | Near_Call | 02H |
| | | All_branches | 04H |
| | | Not_Taken | 10H |
| | | Taken | 20H |
| MEM_UOPS_RETIRED | D0H | STLB_MISS_LOADS | 11H |
| | | STLB_MISS_STORE | 12H |
| | | LOCK_LOADS | 21H |
| | | SPLIT_LOADS | 41H |
| | | SPLIT_STORES | 42H |
| | | ALL_LOADS | 81H |
| | | ALL_STORES | 82H |
| MEM_LOAD_UOPS_RETIRED | D1H | L1_Hit | 01H |
| | | L2_Hit | 02H |
| | | L3_Hit | 04H |
| | | Hit_LFB | 40H |
| MEM_LOAD_UOPS_LLC_HIT_RETIRED | D2H | XSNP_Miss | 01H |
| | | XSNP_Hit | 02H |
| | | XSNP_Hitm | 04H |
| | | XSNP_None | 08H |

**NOTES:**

1. Only available on IA32_PMC1.

### 18.9.4.2 Load Latency Performance Monitoring Facility

The load latency facility in Intel microarchitecture code name Sandy Bridge is similar to that in prior microarchitecture. It provides software a means to characterize the average load latency to different levels of cache/memory hierarchy. This facility requires processor supporting enhanced PEBS record format in the PEBS buffer, see Table 18-18 and Section 18.9.4.1. This field measures the load latency from load's first dispatch of till final data writeback from the memory subsystem. The latency is reported for retired demand load operations and in core cycles (it accounts for re-dispatches).

To use this feature software must assure:

- One of the IA32_PERFEVTSELx MSR is programmed to specify the event unit MEM_TRANS_RETIRED, and the LATENCY_ABOVE_THRESHOLD event mask must be specified (IA32_PerfEvtSelX[15:0] = 1CDH). The corresponding counter IA32_PMCx will accumulate event counts for architecturally visible loads which exceed the programmed latency threshold specified separately in a MSR. Stores are ignored when this event is programmed. The CMASK or INV fields of the IA32_PerfEvtSelX register used for counting load latency must be 0. Writing other values will result in undefined behavior.
- The MSR_PEBS_LD_LAT_THRESHOLD MSR is programmed with the desired latency threshold in core clock cycles. Loads with latencies greater than this value are eligible for counting and latency data reporting. The minimum value that may be programmed in this register is 3 (the minimum detectable load latency is 4 core clock cycles).
- The PEBS enable bit in the IA32_PEBS_ENABLE register is set for the corresponding IA32_PMCx counter register. This means that both the PEBS_EN_CTRX and LL_EN_CTRX bits must be set for the counter(s) of interest. For example, to enable load latency on counter IA32_PMC0, the IA32_PEBS_ENABLE register must be programmed with the 64-bit value 00000001.00000001H.

- When Load latency event is enabled, no other PEBS event can be configured with other counters.

When the load-latency facility is enabled, load operations are randomly selected by hardware and tagged to carry information related to data source locality and latency. Latency and data source information of tagged loads are updated internally. The MEM_TRANS_RETIRED event for load latency counts only tagged retired loads. If a load is cancelled it will not be counted and the internal state of the load latency facility will not be updated. In this case the hardware will tag the next available load.

When a PEBS assist occurs, the last update of latency and data source information are captured by the assist and written as part of the PEBS record. The PEBS sample after value (SAV), specified in PEBS CounterX Reset, operates orthogonally to the tagging mechanism. Loads are randomly tagged to collect latency data. The SAV controls the number of tagged loads with latency information that will be written into the PEBS record field by the PEBS assists. The load latency data written to the PEBS record will be for the last tagged load operation which retired just before the PEBS assist was invoked.

The physical layout of the PEBS records is the same as shown in Table 18-18. The specificity of Data Source entry at offset A0H has been enhanced to report three piece of information.

**Table 18-28. Layout of Data Source Field of Load Latency Record**

| Field | Position | Description |
|---|---|---|
| Source | 3:0 | See Table 18-19 |
| STLB_MISS | 4 | 0: The load did not miss the STLB (hit the DTLB or STLB).<br>1: The load missed the STLB. |
| Lock | 5 | 0: The load was not part of a locked transaction.<br>1: The load was part of a locked transaction. |
| Reserved | 63:6 | Reserved |

The layout of MSR_PEBS_LD_LAT_THRESHOLD is the same as shown in Figure 18-19.

### 18.9.4.3 Precise Store Facility

Processors based on Intel microarchitecture code name Sandy Bridge offer a precise store capability that complements the load latency facility. It provides a means to profile store memory references in the system.

Precise stores leverage the PEBS facility and provide additional information about sampled stores. Having precise memory reference events with linear address information for both loads and stores can help programmers improve data structure layout, eliminate remote node references, and identify cache-line conflicts in NUMA systems.

Only IA32_PMC3 can be used to capture precise store information. After enabling this facility, counter overflows will initiate the generation of PEBS records as previously described in PEBS. Upon counter overflow hardware captures the linear address and other status information of the next store that retires. This information is then written to the PEBS record.

To enable the precise store facility, software must complete the following steps. Please note that the precise store facility relies on the PEBS facility, so the PEBS configuration requirements must be completed before attempting to capture precise store information.

- Complete the PEBS configuration steps.
- Program the MEM_TRANS_RETIRED.PRECISE_STORE event in IA32_PERFEVTSEL3. Only counter 3 (IA32_PMC3) supports collection of precise store information.
- Set IA32_PEBS_ENABLE[3] and IA32_PEBS_ENABLE[63]. This enables IA32_PMC3 as a PEBS counter and enables the precise store facility, respectively.

The precise store information written into a PEBS record affects entries at offset 98H, A0H and A8H of Table 18-18. The specificity of Data Source entry at offset A0H has been enhanced to report three piece of information.

Table 18-29. Layout of Precise Store Information In PEBS Record

| Field | Offset | Description |
|---|---|---|
| Store Data Linear Address | 98H | The linear address of the destination of the store. |
| Store Status | A0H | L1D Hit (Bit 0): The store hit the data cache closest to the core (lowest latency cache) if this bit is set, otherwise the store missed the data cache.<br>STLB Miss (bit 4): The store missed the STLB if set, otherwise the store hit the STLB<br>Locked Access (bit 5): The store was part of a locked access if set, otherwise the store was not part of a locked access. |
| Reserved | A8H | Reserved |

### 18.9.4.4 Precise Distribution of Instructions Retired (PDIR)

Upon triggering a PEBS assist, there will be a finite delay between the time the counter overflows and when the microcode starts to carry out its data collection obligations. INST_RETIRED is a very common event that is used to sample where performance bottleneck happened and to help identify its location in instruction address space. Even if the delay is constant in core clock space, it invariably manifest as variable "skids" in instruction address space. This creates a challenge for programmers to profile a workload and pinpoint the location of bottlenecks.

The core PMU in processors based on Intel microarchitecture code name Sandy Bridge include a facility referred to as precise distribution of Instruction Retired (PDIR).

The PDIR facility mitigates the "skid" problem by providing an early indication of when the INST_RETIRED counter is about to overflow, allowing the machine to more precisely trap on the instruction that actually caused the counter overflow thus eliminating skid.

PDIR applies only to the INST_RETIRED.ALL precise event, and must use IA32_PMC1 with PerfEvtSel1 property configured and bit 1 in the IA32_PEBS_ENABLE set to 1. INST_RETIRED.ALL is a non-architectural performance event, it is not supported in prior generation microarchitectures. Additionally, on processors with CPUID DisplayFamily_DisplayModel signatures of 06_2A and 06_2D, the tool that programs PDIR should quiesce the rest of the programmable counters in the core when PDIR is active.

## 18.9.5 Off-core Response Performance Monitoring

The core PMU in processors based on Intel microarchitecture code name Sandy Bridge provides off-core response facility similar to prior generation. Off-core response can be programmed only with a specific pair of event select and counter MSR, and with specific event codes and predefine mask bit value in a dedicated MSR to specify attributes of the off-core transaction. Two event codes are dedicated for off-core response event programming. Each event code for off-core response monitoring requires programming an associated configuration MSR, MSR_OFFCORE_RSP_x. Table 18-30 lists the event code, mask value and additional off-core configuration MSR that must be programmed to count off-core response events using IA32_PMCx.

Table 18-30. Off-Core Response Event Encoding

| Counter | Event code | UMask | Required Off-core Response MSR |
|---|---|---|---|
| PMC0-3 | B7H | 01H | MSR_OFFCORE_RSP_0 (address 1A6H) |
| PMC0-3 | BBH | 01H | MSR_OFFCORE_RSP_1 (address 1A7H) |

The layout of MSR_OFFCORE_RSP_0 and MSR_OFFCORE_RSP_1 are shown in Figure 18-32 and Figure 18-33. Bits 15:0 specifies the request type of a transaction request to the uncore. Bits 30:16 specifies supplier information, bits 37:31 specifies snoop response information.

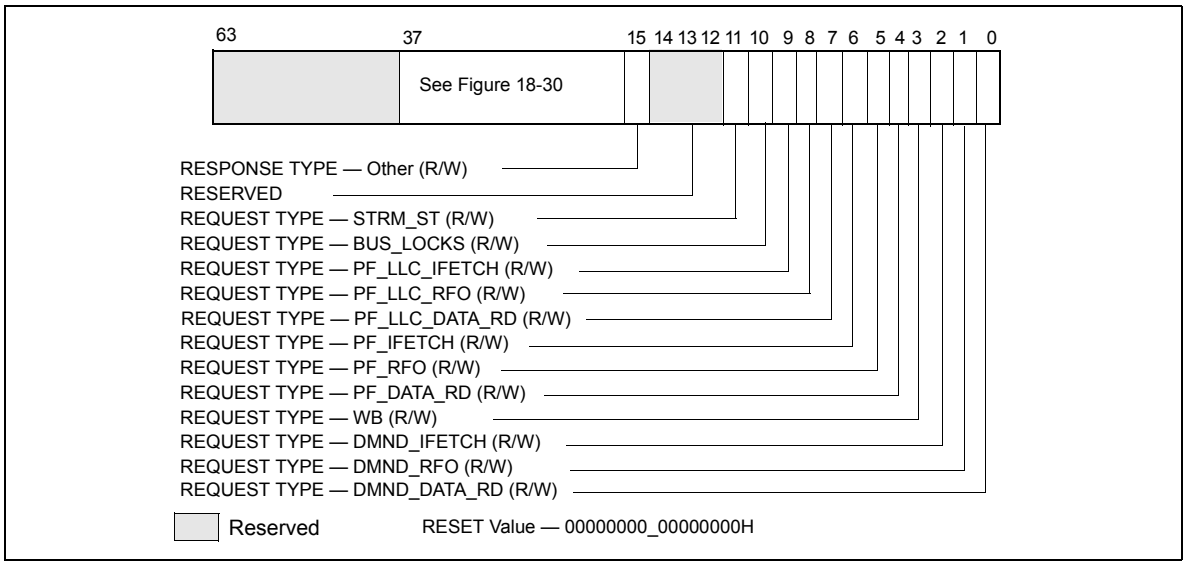

**Figure 18-32. Request_Type Fields for MSR_OFFCORE_RSP_x**

**Table 18-31. MSR_OFFCORE_RSP_x Request_Type Field Definition**

| Bit Name | Offset | Description |
|---|---|---|
| DMND_DATA_RD | 0 | (R/W). Counts the number of demand and DCU prefetch data reads of full and partial cachelines as well as demand data page table entry cacheline reads. Does not count L2 data read prefetches or instruction fetches. |
| DMND_RFO | 1 | (R/W). Counts the number of demand and DCU prefetch reads for ownership (RFO) requests generated by a write to data cacheline. Does not count L2 RFO prefetches. |
| DMND_IFETCH | 2 | (R/W). Counts the number of demand and DCU prefetch instruction cacheline reads. Does not count L2 code read prefetches. |
| WB | 3 | (R/W). Counts the number of writeback (modified to exclusive) transactions. |
| PF_DATA_RD | 4 | (R/W). Counts the number of data cacheline reads generated by L2 prefetchers. |
| PF_RFO | 5 | (R/W). Counts the number of RFO requests generated by L2 prefetchers. |
| PF_IFETCH | 6 | (R/W). Counts the number of code reads generated by L2 prefetchers. |
| PF_LLC_DATA_RD | 7 | (R/W). L2 prefetcher to L3 for loads. |
| PF_LLC_RFO | 8 | (R/W). RFO requests generated by L2 prefetcher |
| PF_LLC_IFETCH | 9 | (R/W). L2 prefetcher to L3 for instruction fetches. |
| BUS_LOCKS | 10 | (R/W). Bus lock and split lock requests |
| STRM_ST | 11 | (R/W). Streaming store requests |
| OTHER | 15 | (R/W). Any other request that crosses IDI, including I/O. |

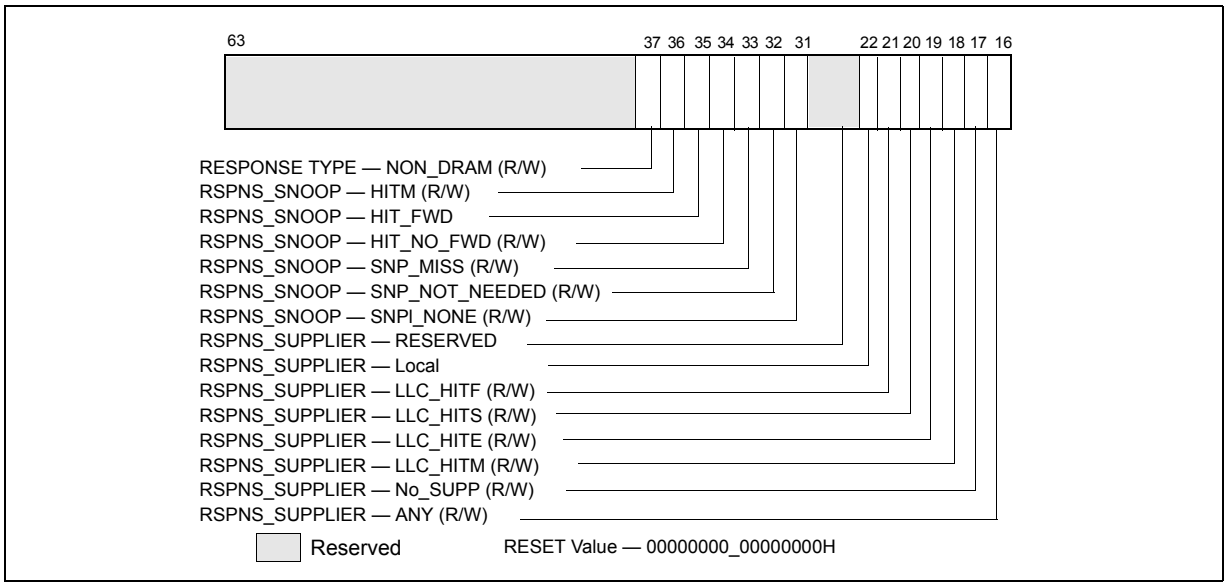

**Figure 18-33. Response_Supplier and Snoop Info Fields for MSR_OFFCORE_RSP_x**

To properly program this extra register, software must set at least one request type bit and a valid response type pattern. Otherwise, the event count reported will be zero. It is permissible and useful to set multiple request and response type bits in order to obtain various classes of off-core response events. Although MSR_OFFCORE_RSP_x allow an agent software to program numerous combinations that meet the above guideline, not all combinations produce meaningful data.

**Table 18-32. MSR_OFFCORE_RSP_x Response Supplier Info Field Definition**

| Subtype | Bit Name | Offset | Description |
|---|---|---|---|
| Common | Any | 16 | (R/W). Catch all value for any response types. |
| Supplier Info | NO_SUPP | 17 | (R/W). No Supplier Information available |
| | LLC_HITM | 18 | (R/W). M-state initial lookup stat in L3. |
| | LLC_HITE | 19 | (R/W). E-state |
| | LLC_HITS | 20 | (R/W). S-state |
| | LLC_HITF | 21 | (R/W). F-state |
| | LOCAL | 22 | (R/W). Local DRAM Controller |
| | Reserved | 30:23 | Reserved |

To specify a complete offcore response filter, software must properly program bits in the request and response type fields. A valid request type must have at least one bit set in the non-reserved bits of 15:0. A valid response type must be a non-zero value of the following expression:

ANY | [(‘OR’ of Supplier Info Bits) & (‘OR’ of Snoop Info Bits)]

If “ANY“ bit is set, the supplier and snoop info bits are ignored.

**Table 18-33. MSR_OFFCORE_RSP_x Snoop Info Field Definition**

| Subtype | Bit Name | Offset | Description |
|---|---|---|---|
| Snoop Info | SNP_NONE | 31 | (R/W). No details on snoop-related information |
| | SNP_NOT_NEEDED | 32 | (R/W). No snoop was needed to satisfy the request. |
| | SNP_MISS | 33 | (R/W). A snoop was needed and it missed all snooped caches:<br>-For LLC Hit, ReslHitI was returned by all cores<br>-For LLC Miss, RspI was returned by all sockets and data was returned from DRAM. |
| | SNP_NO_FWD | 34 | (R/W). A snoop was needed and it hits in at least one snooped cache. Hit denotes a cache-line was valid before snoop effect. This includes:<br>-Snoop Hit w/ Invalidation (LLC Hit, RFO)<br>-Snoop Hit, Left Shared (LLC Hit/Miss, IFetch/Data_RD)<br>-Snoop Hit w/ Invalidation and No Forward (LLC Miss, RFO Hit S)<br>In the LLC Miss case, data is returned from DRAM. |
| | SNP_FWD | 35 | (R/W). A snoop was needed and data was forwarded from a remote socket. This includes:<br>-Snoop Forward Clean, Left Shared (LLC Hit/Miss, IFetch/Data_RD/RFT). |
| | HITM | 36 | (R/W). A snoop was needed and it HitM-ed in local or remote cache. HitM denotes a cache-line was in modified state before effect as a results of snoop. This includes:<br>-Snoop HitM w/ WB (LLC miss, IFetch/Data_RD)<br>-Snoop Forward Modified w/ Invalidation (LLC Hit/Miss, RFO)<br>-Snoop MtoS (LLC Hit, IFetch/Data_RD). |
| | NON_DRAM | 37 | (R/W). Target was non-DRAM system address. This includes MMIO transactions. |

## 18.9.6 Uncore Performance Monitoring Facilities In Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series

The uncore sub-system in Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx processor series provides a unified L3 that can support up to four processor cores. The L3 cache consists multiple slices, each slice interface with a processor via a coherence engine, referred to as a C-Box. Each C-Box provides dedicated facility of MSRs to select uncore performance monitoring events and each C-Box event select MSR is paired with a counter register, similar in style as those described in Section 18.7.2.2. The ARB unit in the uncore also provides its local performance counters and event select MSRs. The layout of the event select MSRs in the C-Boxes and the ARB unit are shown in Figure 18-34.

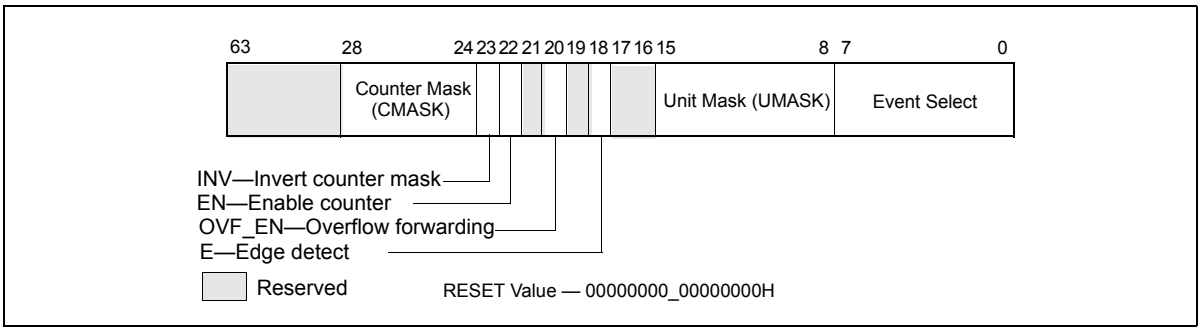

**Figure 18-34. Layout of Uncore PERFEVTSEL MSR for a C-Box Unit or the ARB Unit**

The bit fields of the uncore event select MSRs for a C-box unit or the ARB unit are summarized below:

- Event_Select (bits 7:0) and UMASK (bits 15:8): Specifies the microarchitectural condition to count in a local uncore PMU counter, see Table 19-12.
- E (bit 18): Enables edge detection filtering, if 1.
- OVF_EN (bit 20): Enables the overflow indicator from the uncore counter forwarded to MSR_UNC_PERF_GLOBAL_CTRL, if 1.
- EN (bit 22): Enables the local counter associated with this event select MSR.
- INV (bit 23): Event count increments with non-negative value if 0, with negated value if 1.
- CMASK (bits 28:24): Specifies a positive threshold value to filter raw event count input.

At the uncore domain level, there is a master set of control MSRs that centrally manages all the performance monitoring facility of uncore units. Figure 18-35 shows the layout of the uncore domain global control.

When an uncore counter overflows, a PMI can be routed to a processor core. Bits 3:0 of MSR_UNC_PERF_GLOBAL_CTRL can be used to select which processor core to handle the uncore PMI. Software must then write to bit 13 of IA32_DEBUG_CTL (at address 1D9H) to enable this capability.

- PMI_SEL_Core#: Enables the forwarding of an uncore PMI request to a processor core, if 1. If bit 30 (WakePMI) is '1', a wake request is sent to the respective processor core prior to sending the PMI.
- EN: Enables the fixed uncore counter, the ARB counters, and the CBO counters in the uncore PMU, if 1. This bit is cleared if bit 31 (FREEZE) is set and any enabled uncore counters overflow.
- WakePMI: Controls sending a wake request to any halted processor core before issuing the uncore PMI request. If a processor core was halted and not sent a wake request, the uncore PMI will not be serviced by the processor core.
- FREEZE: Provides the capability to freeze all uncore counters when an overflow condition occurs in a unit counter. When this bit is set, and a counter overflow occurs, the uncore PMU logic will clear the global enable bit (bit 29).

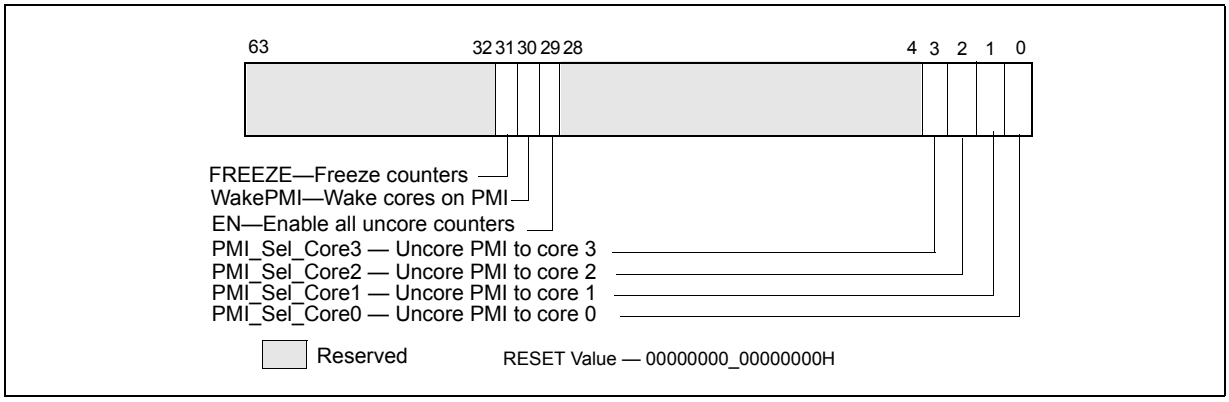

**Figure 18-35. Layout of MSR_UNC_PERF_GLOBAL_CTRL MSR for Uncore**

Additionally, there is also a fixed counter, counting uncore clockticks, for the uncore domain. Table 18-34 summarizes the number MSRs for uncore PMU for each box.

**Table 18-34. Uncore PMU MSR Summary**

| Box | # of Boxes | Counters per Box | Counter Width | General Purpose | Global Enable | Comment |
|---|---|---|---|---|---|---|
| C-Box | SKU specific | 2 | 44 | Yes | Per-box | Up to 4, seeTable 35-16 MSR_UNC_CBO_CONFIG |
| ARB | 1 | 2 | 44 | Yes | Uncore | |

Table 18-34. Uncore PMU MSR Summary (Contd.)

| Box | # of Boxes | Counters per Box | Counter Width | General Purpose | Global Enable | Comment |
|---|---|---|---|---|---|---|
| Fixed Counter | N.A. | N.A. | 48 | No | Uncore | |

### 18.9.6.1 Uncore Performance Monitoring Events

There are certain restrictions on the uncore performance counters in each C-Box. Specifically,

- Occupancy events are supported only with counter 0 but not counter 1.

Other uncore C-Box events can be programmed with either counter 0 or 1.

The C-Box uncore performance events described in Table 19-12 can collect performance characteristics of transactions initiated by processor core. In that respect, they are similar to various sub-events in the OFFCORE_RESPONSE family of performance events in the core PMU. Information such as data supplier locality (LLC HIT/MISS) and snoop responses can be collected via OFFCORE_RESPONSE and qualified on a per-thread basis.

On the other hand, uncore performance event logic can not associate its counts with the same level of per-thread qualification attributes as the core PMU events can. Therefore, whenever similar event programming capabilities are available from both core PMU and uncore PMU, the recommendation is that utilizing the core PMU events may be less affected by artifacts, complex interactions and other factors.

## 18.9.7 Intel® Xeon® Processor E5 Family Performance Monitoring Facility

The Intel® Xeon® Processor E5 Family (and Intel® Core™ i7-3930K Processor) are based on Intel microarchitecture code name Sandy Bridge-E. While the processor cores share the same microarchitecture as those of the Intel® Xeon® Processor E3 Family and 2nd generation Intel Core i7-2xxx, Intel Core i5-2xxx, Intel Core i3-2xxx processor series, the uncore subsystems are different. An overview of the uncore performance monitoring facilities of the Intel Xeon processor E5 family (and Intel Core i7-3930K processor) is described in Section 18.9.8.

Thus, the performance monitoring facilities in the processor core generally are the same as those described in Section 18.9 through Section 18.9.5. However, the MSR_OFFCORE_RSP_0/MSR_OFFCORE_RSP_1 Response Supplier Info field shown in Table 18-32 applies to Intel Core Processors with CPUID signature of DisplayFamily_DisplayModel encoding of 06_2AH; Intel Xeon processor with CPUID signature of DisplayFamily_DisplayModel encoding of 06_2DH supports an additional field for remote DRAM controller shown in Table 18-35. Additionally, the are some small differences in the non-architectural performance monitoring events (see Table 19-10).

Table 18-35. MSR_OFFCORE_RSP_x Supplier Info Field Definitions

| Subtype | Bit Name | Offset | Description |
|---|---|---|---|
| Common | Any | 16 | (R/W). Catch all value for any response types. |
| Supplier Info | NO_SUPP | 17 | (R/W). No Supplier Information available |
| | LLC_HITM | 18 | (R/W). M-state initial lookup stat in L3. |
| | LLC_HITE | 19 | (R/W). E-state |
| | LLC_HITS | 20 | (R/W). S-state |
| | LLC_HITF | 21 | (R/W). F-state |
| | LOCAL | 22 | (R/W). Local DRAM Controller |
| | Remote | 30:23 | (R/W): Remote DRAM Controller (either all 0s or all 1s) |

### 18.9.8 Intel® Xeon® Processor E5 Family Uncore Performance Monitoring Facility

The uncore subsystem in the Intel Xeon processor E5-2600 product family has some similarities with those of the Intel Xeon processor E7 family. Within the uncore subsystem, localized performance counter sets are provided at logic control unit scope. For example, each Cbox caching agent has a set of local performance counters, and the power controller unit (PCU) has its own local performance counters. Up to 8 C-Box units are supported in the uncore sub-system.

Table 18-36 summarizes the uncore PMU facilities providing MSR interfaces.

**Table 18-36. Uncore PMU MSR Summary for Intel® Xeon® Processor E5 Family**

| Box | # of Boxes | Counters per Box | Counter Width | General Purpose | Global Enable | Sub-control MSRs |
|---|---|---|---|---|---|---|
| C-Box | 8 | 4 | 44 | Yes | per-box | None |
| PCU | 1 | 4 | 48 | Yes | per-box | Match/Mask |
| U-Box | 1 | 2 | 44 | Yes | uncore | None |

Details of the uncore performance monitoring facility of Intel Xeon Processor E5 family is available in "Intel® Xeon® Processor E5 Uncore Performance Monitoring Programming Reference Manual".

## 18.10 3RD GENERATION INTEL® CORE™ PROCESSOR PERFORMANCE MONITORING FACILITY

The 3rd generation Intel® Core™ processor family and Intel® Xeon® processor E3-1200v2 product family are based on the Ivy Bridge microarchitecture. The performance monitoring facilities in the processor core generally are the same as those described in Section 18.9 through Section 18.9.5. The non-architectural performance monitoring events supported by the processor core are listed in Table 19-10.

### 18.10.1 Intel® Xeon® Processor E5 v2 and E7 v2 Family Uncore Performance Monitoring Facility

The uncore subsystem in the Intel Xeon processor E5 v2 and Intel Xeon Processor E7 v2 product families are based on the Ivy Bridge-E microarchitecture. There are some similarities with those of the Intel Xeon processor E5 family based on the Sandy Bridge microarchitecture. Within the uncore subsystem, localized performance counter sets are provided at logic control unit scope.

Details of the uncore performance monitoring facility of Intel Xeon Processor E5 v2 and Intel Xeon Processor E7 v2 families are available in "Intel® Xeon® Processor E5 v2 and E7 v2 Uncore Performance Monitoring Programming Reference Manual".

## 18.11 4TH GENERATION INTEL® CORE™ PROCESSOR PERFORMANCE MONITORING FACILITY

The 4th generation Intel® Core™ processor and Intel® Xeon® processor E3-1200 v3 product family are based on the Haswell microarchitecture. The core PMU supports architectural performance monitoring capability with version ID 3 (see Section 18.2.2.2) and a host of non-architectural monitoring capabilities.

Architectural performance monitoring events and non-architectural monitoring events are programmed using fixed counters and programmable counters/event select MSRS as described in Section 18.2.2.2.

The core PMU's capability is similar to those described in Section 18.9 through Section 18.9.5, with some differences and enhancements summarized in Table 18-37. Additionally, the core PMU provides some enhancement to support performance monitoring when the target workload contains instruction streams using Intel® Transactional

Synchronization Extensions (TSX), see Section 18.11.5. For details of Intel TSX, see Chapter 15, "Programming with Intel® Transactional Synchronization Extensions" of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*.

**Table 18-37. Core PMU Comparison**

| Box | Intel® microarchitecture code name Haswell | Intel® microarchitecture code name Sandy Bridge | Comment |
|---|---|---|---|
| # of Fixed counters per thread | 3 | 3 | |
| # of general-purpose counters per core | 8 | 8 | |
| Counter width (R,W) | R:48 , W: 32/48 | R:48 , W: 32/48 | See Section 18.2.2.3. |
| # of programmable counters per thread | 4 or (8 if a core not shared by two threads) | 4 or (8 if a core not shared by two threads) | Use CPUID to enumerate # of counters. |
| Precise Event Based Sampling (PEBS) Events | See Table 18-27 | See Table 18-27 | IA32_PMC4-IA32_PMC7 do not support PEBS. |
| PEBS-Load Latency | See Section 18.9.4.2; | See Section 18.9.4.2; | |
| PEBS-Precise Store | No, replaced by Data Address profiling | Section 18.9.4.3 | |
| PEBS-PDIR | yes (using precise INST_RETIRED.ALL) | yes (using precise INST_RETIRED.ALL) | |
| PEBS-EventingIP | yes | no | |
| Data Address Profiling | yes | no | |
| LBR Profiling | yes | yes | |
| Call Stack Profiling | yes, see Section 17.8 | no | Use LBR facility |
| Off-core Response Event | MSR 1A6H and 1A7H; Extended request and response types | MSR 1A6H and 1A7H; Extended request and response types | |
| Intel TSX support for Perfmon | See Section 18.11.5; | no | |

## 18.11.1 Precise Event Based Sampling (PEBS) Facility

The PEBS facility in the Next Generation Intel Core processor is similar to those in processors based on Intel micro-architecture code name Sandy Bridge, with several enhanced features. The key components and differences of PEBS facility relative to Intel microarchitecture code name Sandy Bridge is summarized in Table 18-38.

**Table 18-38. PEBS Facility Comparison**

| Box | Intel® microarchitecture code name Haswell | Intel® microarchitecture code name Sandy Bridge | Comment |
|---|---|---|---|
| Valid IA32_PMCx | PMC0-PMC3 | PMC0-PMC3 | No PEBS on PMC4-PMC7 |
| PEBS Buffer Programming | Section 18.7.1.1 | Section 18.7.1.1 | Unchanged |
| IA32_PEBS_ENABLE Layout | Figure 18-17 | Figure 18-31 | |
| PEBS record layout | Table 18-39, Enhanced fields at offsets 98H, A0H, A8H, B0H | Table 18-18, Enhanced fields at offsets 98H, A0H, A8H | |
| PEBS Events | See Table 18-27 | See Table 18-27 | IA32_PMC4-IA32_PMC7 do not support PEBS. |
| PEBS-Load Latency | See Table 18-28 | Table 18-28 | |

Table 18-38. PEBS Facility Comparison

| Box | Intel® microarchitecture code name Haswell | Intel® microarchitecture code name Sandy Bridge | Comment |
|---|---|---|---|
| PEBS-Precise Store | no, replaced by data address profiling | yes; see Section 18.9.4.3 | |
| PEBS-PDIR | yes | yes | IA32_PMC1 only |
| PEBS skid from EventingIP | 1 (or 2 if micro+macro fusion) | 1 | |
| SAMPLING Restriction | Small SAV(CountDown) value incur higher overhead than prior generation. | | |

Only IA32_PMC0 through IA32_PMC3 support PEBS.

**NOTE**

PEBS events are only valid when the following fields of IA32_PERFEVTSELx are all zero: AnyThread, Edge, Invert, CMask.

In a PMU with PDIR capability, PEBS behavior is unpredictable if IA32_PERFEVTSELx or IA32_PMCx is changed for a PEBS-enabled counter while an event is being counted. To avoid this, changes to the programming or value of a PEBS-enabled counter should be performed when the counter is disabled.

## 18.11.2 PEBS Data Format

The PEBS record format for the Next Generation Intel Core processor is shown in Table 18-39. The PEBS record format, along with debug/store area storage format, does not change regardless of whether IA-32e mode is active or not. CPUID.01H:ECX.DTES64[bit 2] reports whether the processor's DS storage format support is mode-independent. When set, it uses 64-bit DS storage format.

Table 18-39. PEBS Record Format for Next Generation Intel Core Processor Family

| Byte Offset | Field | Byte Offset | Field |
|---|---|---|---|
| 00H | R/EFLAGS | 60H | R10 |
| 08H | R/EIP | 68H | R11 |
| 10H | R/EAX | 70H | R12 |
| 18H | R/EBX | 78H | R13 |
| 20H | R/ECX | 80H | R14 |
| 28H | R/EDX | 88H | R15 |
| 30H | R/ESI | 90H | IA32_PERF_GLOBAL_STATUS |
| 38H | R/EDI | 98H | Data Linear Address |
| 40H | R/EBP | A0H | Data Source Encoding |
| 48H | R/ESP | A8H | Latency value (core cycles) |
| 50H | R8 | B0H | EventingIP |
| 58H | R9 | B8H | TX Abort Information (Section 18.11.5.1 ) |

The layout of PEBS records are almost identical to those shown in Table 18-18. Offset B0H is a new field that records the eventing IP address of the retired instruction that triggered the PEBS assist.

The PEBS records at offsets 98H, A0H, and ABH record data gathered from three of the PEBS capabilities in prior processor generations: load latency facility (Section 18.9.4.2), PDIR (Section 18.9.4.4), and precise store (Section 18.9.4.3).

In the core PMU of the next generation processor, load latency facility and PDIR capabilities are unchanged. However, precise store is replaced by an enhanced capability, data address profiling, that is not restricted to store address. Data address profiling also records information in PEBS records at offsets 98H, A0H, and ABH.

## 18.11.3 PEBS Data Address Profiling

The Data Linear Address facility is also abbreviated as DataLA. The facility is a replacement or extension of the precise store facility in previous processor generations. The DataLA facility complements the load latency facility by providing a means to profile load and store memory references in the system, leverages the PEBS facility, and provides additional information about sampled loads and stores. Having precise memory reference events with linear address information for both loads and stores provides information to improve data structure layout, eliminate remote node references, and identify cache-line conflicts in NUMA systems.

The DataLA facility in the next generation processor supports the following events configured to use PEBS:

**Table 18-40. Precise Events That Supports Data Linear Address Profiling**

| Event Name | Event Name |
|---|---|
| MEM_UOPS_RETIRED.STLB_MISS_LOADS | MEM_UOPS_RETIRED.STLB_MISS_STORES |
| MEM_UOPS_RETIRED.LOCK_LOADS | MEM_UOPS_RETIRED.SPLIT_STORES |
| MEM_UOPS_RETIRED.SPLIT_LOADS | MEM_UOPS_RETIRED.ALL_STORES |
| MEM_UOPS_RETIRED.ALL_LOADS | MEM_LOAD_UOPS_LLC_MISS_RETIRED.LOCAL_DRAM |
| MEM_LOAD_UOPS_RETIRED.L1_HIT | MEM_LOAD_UOPS_RETIRED.L2_HIT |
| MEM_LOAD_UOPS_RETIRED.L3_HIT | MEM_LOAD_UOPS_RETIRED.L1_MISS |
| MEM_LOAD_UOPS_RETIRED.L2_MISS | MEM_LOAD_UOPS_RETIRED.L3_MISS |
| MEM_LOAD_UOPS_RETIRED.HIT_LFB | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_MISS |
| MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_HIT | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_HITM |
| UOPS_RETIRED.ALL (if load or store is tagged) | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_NONE |

DataLA can use any one of the IA32_PMC0-IA32_PMC3 counters. Counter overflows will initiate the generation of PEBS records. Upon counter overflow, hardware captures the linear address and possible other status information of the retiring memory uop. This information is then written to the PEBS record that is subsequently generated.

To enable the DataLA facility, software must complete the following steps. Please note that the DataLA facility relies on the PEBS facility, so the PEBS configuration requirements must be completed before attempting to capture DataLA information.

- Complete the PEBS configuration steps.
- Program the an event listed in Table 18-40 using any one of IA32_PERFEVTSEL0-IA32_PERFEVTSEL3.
- Set the corresponding IA32_PEBS_ENABLE.PEBS_EN_CTRx bit. This enables the corresponding IA32_PMCx as a PEBS counter and enables the DataLA facility.

When the DataLA facility is enabled, the relevant information written into a PEBS record affects entries at offsets 98H, A0H and A8H, as shown in Table 18-41.

**Table 18-41. Layout of Data Linear Address Information In PEBS Record**

| Field | Offset | Description |
|---|---|---|
| Data Linear Address | 98H | The linear address of the load or the destination of the store. |

Table 18-41. Layout of Data Linear Address Information In PEBS Record (Contd.)

| Field | Offset | Description |
|---|---|---|
| Store Status | A0H | ▪ **DCU Hit** (Bit 0): The store hit the data cache closest to the core (L1 cache) if this bit is set, otherwise the store missed the data cache. This information is valid only for the following store events: UOPS_RETIRED.ALL (if store is tagged), MEM_UOPS_RETIRED.STLB_MISS_STORES, MEM_UOPS_RETIRED.LOCK_STORES, MEM_UOPS_RETIRED.SPLIT_STORES, MEM_UOPS_RETIRED.ALL_STORES<br>▪ Other bits are zero, The STLB_MISS, LOCK bit information can be obtained by programming the corresponding store event in Table 18-40. |
| Reserved | A8H | Always zero |

### 18.11.3.1 EventingIP Record

The PEBS record layout for processors based on Intel microarchitecture code name Haswell adds a new field at offset 0B0H. This is the eventingIP field that records the IP address of the retired instruction that triggered the PEBS assist. The EIP/RIP field at offset 08H records the IP address of the next instruction to be executed following the PEBS assist.

## 18.11.4 Off-core Response Performance Monitoring

The core PMU facility to collect off-core response events are similar to those described in Section 18.9.5. The event codes are listed in Table 18-30. Each event code for off-core response monitoring requires programming an associated configuration MSR, MSR_OFFCORE_RSP_x. Software must program MSR_OFFCORE_RSP_x according to:

- Transaction request type encoding (bits 15:0): see Table 18-42.
- Supplier information (bits 30:16): see Table 18-32.
- Snoop response information (bits 37:31): see Table 18-33.

Table 18-42. MSR_OFFCORE_RSP_x Request_Type Definition (Intel® microarchitecture code name Haswell)

| Bit Name | Offset | Description |
|---|---|---|
| DMND_DATA_RD | 0 | (R/W). Counts the number of demand and DCU prefetch data reads of full and partial cachelines as well as demand data page table entry cacheline reads. Does not count L2 data read prefetches or instruction fetches. |
| DMND_RFO | 1 | (R/W). Counts the number of demand and DCU prefetch reads for ownership (RFO) requests generated by a write to data cacheline. Does not count L2 RFO prefetches. |
| DMND_IFETCH | 2 | (R/W). Counts the number of demand and DCU prefetch instruction cacheline reads. Does not count L2 code read prefetches. |
| Reserved | 3 | Reserved |
| PF_DATA_RD | 4 | (R/W). Counts the number of data cacheline reads generated by L2 prefetchers. |
| PF_RFO | 5 | (R/W). Counts the number of RFO requests generated by L2 prefetchers. |
| PF_IFETCH | 6 | (R/W). Counts the number of code reads generated by L2 prefetchers. |
| Reserved | 7-14 | Reserved |
| OTHER | 15 | (R/W). Any other request that crosses IDI, including I/O. |

## 18.11.5 Performance Monitoring and Intel® TSX

Chapter 15 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1* describes the details of Intel® Transactional Synchronization Extensions (Intel TSX). This section describes performance monitoring support for Intel TSX.

If a processor supports Intel TSX, the core PMU enhances it's IA32_PERFEVTSELx MSR with two additional bit fields for event filtering. Support for Intel TSX is indicated by either (a) CPUID.(EAX=7, ECX=0):RTM[bit 11]=1, or (b) if CPUID.07H.EBX.HLE [bit 4] = 1. The TSX-enhanced layout of IA32_PERFEVTSELx is shown in Figure 18-36. The two additional bit fields are:

- **IN_TX** (bit 32): When set, the counter will only include counts that occurred inside a transactional region, regardless of whether that region was aborted or committed. This bit may only be set if the processor supports HLE or RTM.
- **IN_TXCP** (bit 33): When set, the counter will not include counts that occurred inside of an aborted transactional region. This bit may only be set if the processor supports HLE or RTM. This bit may only be set for IA32_PERFEVTSEL2.

When the IA32_PERFEVTSELx MSR is programmed with both IN_TX=0 and IN_TXCP=0 on a processor that supports Intel TSX, the result in a counter may include detectable conditions associated with a transaction code region for its aborted execution (if any) and completed execution.

In the initial implementation, software may need to take pre-caution when using the IN_TXCP bit. see Table 35-21.

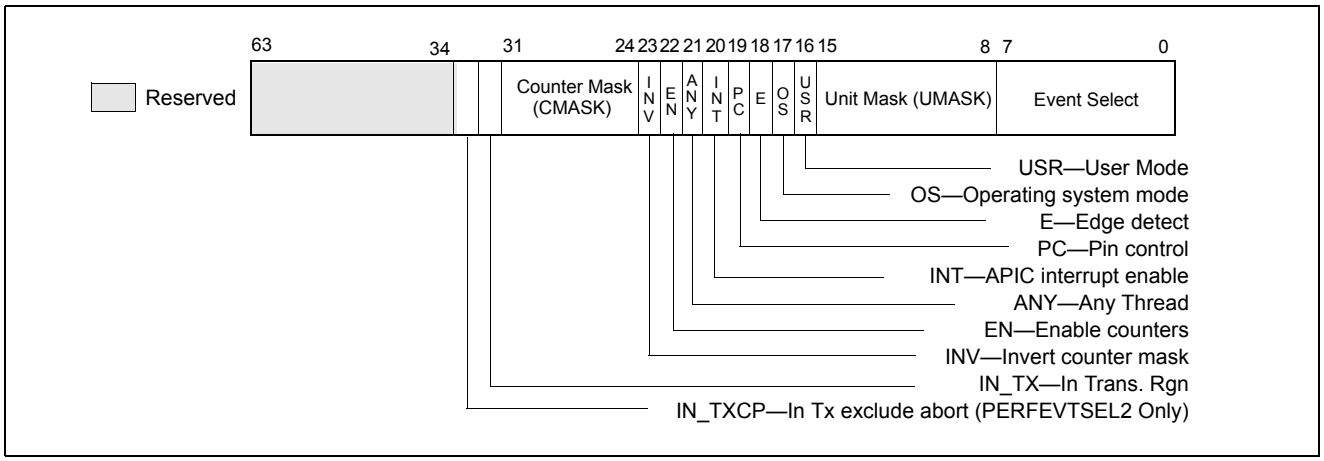

**Figure 18-36. Layout of IA32_PERFEVTSELx MSRs Supporting Intel TSX**

A common usage of setting IN_TXCP=1 is to capture the number of events that were discarded due to a transactional abort. With IA32_PMC2 configured to count in such a manner, then when a transactional region aborts, the value for that counter is restored to the value it had prior to the aborted transactional region. As a result, any updates performed to the counter during the aborted transactional region are discarded.

On the other hand, setting IN_TX=1 can be used to drill down on the performance characteristics of transactional code regions. When a PMCx is configured with the corresponding IA32_PERFEVTSELx.IN_TX=1, only eventing conditions that occur inside transactional code regions are propagated to the event logic and reflected in the counter result. Eventing conditions specified by IA32_PERFEVTSELx but occurring outside a transactional region are discarded. The following example illustrates using three counters to drill down cycles spent inside and outside of transactional regions:

- Program IA32_PERFEVTSEL2 to count Unhalted_Core_Cycles with (IN_TXCP=1, IN_TX=0), such that IA32_PMC2 will count cycles spent due to aborted TSX transactions;
- Program IA32_PERFEVTSEL0 to count Unhalted_Core_Cycles with (IN_TXCP=0, IN_TX=1), such that IA32_PMC0 will count cycles spent by the transactional code regions;
- Program IA32_PERFEVTSEL1 to count Unhalted_Core_Cycles with (IN_TXCP=0, IN_TX=0), such that IA32_PMC1 will count total cycles spent by the non-transactional code and transactional code regions.

Additionally, a number of performance events are solely focused on characterizing the execution of Intel TSX transactional code, they are listed in Table 19-4.

### 18.11.5.1 Intel TSX and PEBS Support

If a PEBS event would have occurred inside a transactional region, then the transactional region first aborts, and then the PEBS event is processed.

Two of the TSX performance monitoring events in Table 19-4 also support using PEBS facility to capture additional information. They are:

- HLE_RETIRED.ABORT ED (encoding C8H mask 04H),
- RTM_RETIRED.ABORTED (encoding C9H mask 04H).

A transactional abort (HLE_RETIRED.ABORTED,RTM_RETIRED.ABORTED) can also be programmed to cause PEBS events. In this scenario, a PEBS event is processed following the abort.

Pending a PEBS record inside of a transactional region will cause a transactional abort. If a PEBS record was pended at the time of the abort or on an overflow of the TSX PEBS events listed above, only the following PEBS entries will be valid (enumerated by PEBS entry offset B8H bits[33:32] to indicate an HLE abort or an RTM abort):

- Offset B0H: EventingIP,
- Offset B8H: TX Abort Information

These fields are set for all PEBS events.

- Offset 08H (RIP/EIP) corresponds to the instruction following the outermost XACQUIRE in HLE or the first instruction of the fallback handler of the outermost XBEGIN instruction in RTM. This is useful to identify the aborted transactional region.

In the case of HLE, an aborted transaction will restart execution deterministically at the start of the HLE region. In the case of RTM, an aborted transaction will transfer execution to the RTM fallback handler.

The layout of the TX Abort Information field is given in Table 18-43.

**Table 18-43. TX Abort Information Field Definition**

| Bit Name | Offset | Description |
|---|---|---|
| Cycles_Last_TX | 31:0 | The number of cycles in the last TSX region, regardless of whether that region had aborted or committed. |
| HLE_Abort | 32 | If set, the abort information corresponds to an aborted HLE execution |
| RTM_Abort | 33 | If set, the abort information corresponds to an aborted RTM execution |
| Instruction_Abort | 34 | If set, the abort was associated with the instruction corresponding to the eventing IP (offset 0B0H) within the transactional region. |
| Non_Instruction_Abort | 35 | If set, the instruction corresponding to the eventing IP may not necessarily be related to the transactional abort. |
| Retry | 36 | If set, retrying the transactional execution may have succeeded. |
| Data_Conflict | 37 | If set, another logical processor conflicted with a memory address that was part of the transactional region that aborted. |
| Capacity Writes | 38 | If set, the transactional region aborted due to exceeding resources for transactional writes. |
| Capacity Reads | 39 | If set, the transactional region aborted due to exceeding resources for transactional reads. |
| Reserved | 63:40 | Reserved |

## 18.11.6 Uncore Performance Monitoring Facilities in the 4th Generation Intel® Core™ Processors

The uncore sub-system in the 4th Generation Intel® Core™ processors provides its own performance monitoring facility. The uncore PMU facility provides dedicated MSRs to select uncore performance monitoring events in a similar manner as those described in Section 18.9.6.

The ARB unit and each C-Box provide local pairs of event select MSR and counter register. The layout of the event select MSRs in the C-Boxes are identical as shown in Figure 18-34.

At the uncore domain level, there is a master set of control MSRs that centrally manages all the performance monitoring facility of uncore units. Figure 18-35 shows the layout of the uncore domain global control.

Additionally, there is also a fixed counter, counting uncore clockticks, for the uncore domain. Table 18-34 summarizes the number MSRs for uncore PMU for each box.

**Table 18-44. Uncore PMU MSR Summary**

| Box | # of Boxes | Counters per Box | Counter Width | General Purpose | Global Enable | Comment |
|---|---|---|---|---|---|---|
| C-Box | SKU specific | 2 | 44 | Yes | Per-box | Up to 4, seeTable 35-16 MSR_UNC_CBO_CONFIG |
| ARB | 1 | 2 | 44 | Yes | Uncore | |
| Fixed Counter | N.A. | N.A. | 48 | No | Uncore | |

The uncore performance events for the C-Box and ARB units are listed in Table 19-5.

## 18.12 INTEL® CORE™ M PROCESSOR PERFORMANCE MONITORING FACILITY

The Intel® Core™ M processor family is based on the Broadwell microarchitecture. The core PMU supports architectural performance monitoring capability with version ID 3 (see Section 18.2.2.2) and a host of non-architectural monitoring capabilities.

Architectural performance monitoring events and non-architectural monitoring events are programmed using fixed counters and programmable counters/event select MSRS as described in Section 18.2.2.2.

The core PMU's capability is the same as those described in Section 18.11. The specifics of non-architectural performance events are listed in Chapter 19, "Performance Monitoring Events".

## 18.13 PERFORMANCE MONITORING (PROCESSORS BASED ON INTEL NETBURST® MICROARCHITECTURE)

The performance monitoring mechanism provided in Pentium 4 and Intel Xeon processors is different from that provided in the P6 family and Pentium processors. While the general concept of selecting, filtering, counting, and reading performance events through the WRMSR, RDMSR, and RDPMC instructions is unchanged, the setup mechanism and MSR layouts are incompatible with the P6 family and Pentium processor mechanisms. Also, the RDPMC instruction has been enhanced to read the the additional performance counters provided in the Pentium 4 and Intel Xeon processors and to allow faster reading of counters.

The event monitoring mechanism provided with the Pentium 4 and Intel Xeon processors (based on Intel NetBurst microarchitecture) consists of the following facilities:

- The IA32_MISC_ENABLE MSR, which indicates the availability in an Intel 64 or IA-32 processor of the performance monitoring and precise event-based sampling (PEBS) facilities.
- Event selection control (ESCR) MSRs for selecting events to be monitored with specific performance counters. The number available differs by family and model (43 to 45).
- 18 performance counter MSRs for counting events.
- 18 counter configuration control (CCCR) MSRs, with one CCCR associated with each performance counter. CCCRs sets up an associated performance counter for a specific method of counting.
- A debug store (DS) save area in memory for storing PEBS records.
- The IA32_DS_AREA MSR, which establishes the location of the DS save area.

- The debug store (DS) feature flag (bit 21) returned by the CPUID instruction, which indicates the availability of the DS mechanism.
- The MSR_PEBS_ENABLE MSR, which enables the PEBS facilities and replay tagging used in at-retirement event counting.
- A set of predefined events and event metrics that simplify the setting up of the performance counters to count specific events.

Table 18-45 lists the performance counters and their associated CCCRs, along with the ESCRs that select events to be counted for each performance counter. Predefined event metrics and events are listed in Chapter 19, "Performance-Monitoring Events."

**Table 18-45. Performance Counter MSRs and Associated CCCR and ESCR MSRs (Pentium 4 and Intel Xeon Processors)**

NOTES:

1. MSR_IQ_ESCR0 and MSR_IQ_ESCR1 are available only on early processor builds (family 0FH, models 01H-02H). These MSRs are not available on later versions.

The types of events that can be counted with these performance monitoring facilities are divided into two classes: non-retirement events and at-retirement events.

- Non-retirement events (see Table 19-23) are events that occur any time during instruction execution (such as bus transactions or cache transactions).
- At-retirement events (see Table 19-24) are events that are counted at the retirement stage of instruction execution, which allows finer granularity in counting events and capturing machine state.

  The at-retirement counting mechanism includes facilities for tagging μops that have encountered a particular performance event during instruction execution. Tagging allows events to be sorted between those that occurred on an execution path that resulted in architectural state being committed at retirement as well as events that occurred on an execution path where the results were eventually cancelled and never committed to architectural state (such as, the execution of a mispredicted branch).

The Pentium 4 and Intel Xeon processor performance monitoring facilities support the three usage models described below. The first two models can be used to count both non-retirement and at-retirement events; the third model is used to count a subset of at-retirement events:

- **Event counting —** A performance counter is configured to count one or more types of events. While the counter is counting, software reads the counter at selected intervals to determine the number of events that have been counted between the intervals.
- **Non-precise event-based sampling —** A performance counter is configured to count one or more types of events and to generate an interrupt when it overflows. To trigger an overflow, the counter is preset to a modulus value that will cause the counter to overflow after a specific number of events have been counted.

  When the counter overflows, the processor generates a performance monitoring interrupt (PMI). The interrupt service routine for the PMI then records the return instruction pointer (RIP), resets the modulus, and restarts the counter. Code performance can be analyzed by examining the distribution of RIPs with a tool like the VTune™ Performance Analyzer.
- **Precise event-based sampling (PEBS) —** This type of performance monitoring is similar to non-precise event-based sampling, except that a memory buffer is used to save a record of the architectural state of the processor whenever the counter overflows. The records of architectural state provide additional information for use in performance tuning. Precise event-based sampling can be used to count only a subset of at-retirement events.

The following sections describe the MSRs and data structures used for performance monitoring in the Pentium 4 and Intel Xeon processors.

## 18.13.1 ESCR MSRs

The 45 ESCR MSRs (see Table 18-45) allow software to select specific events to be countered. Each ESCR is usually associated with a pair of performance counters (see Table 18-45) and each performance counter has several ESCRs associated with it (allowing the events counted to be selected from a variety of events).

Figure 18-37 shows the layout of an ESCR MSR. The functions of the flags and fields are:

- **USR flag, bit 2 —** When set, events are counted when the processor is operating at a current privilege level (CPL) of 1, 2, or 3. These privilege levels are generally used by application code and unprotected operating system code.
- **OS flag, bit 3 —** When set, events are counted when the processor is operating at CPL of 0. This privilege level is generally reserved for protected operating system code. (When both the OS and USR flags are set, events are counted at all privilege levels.)

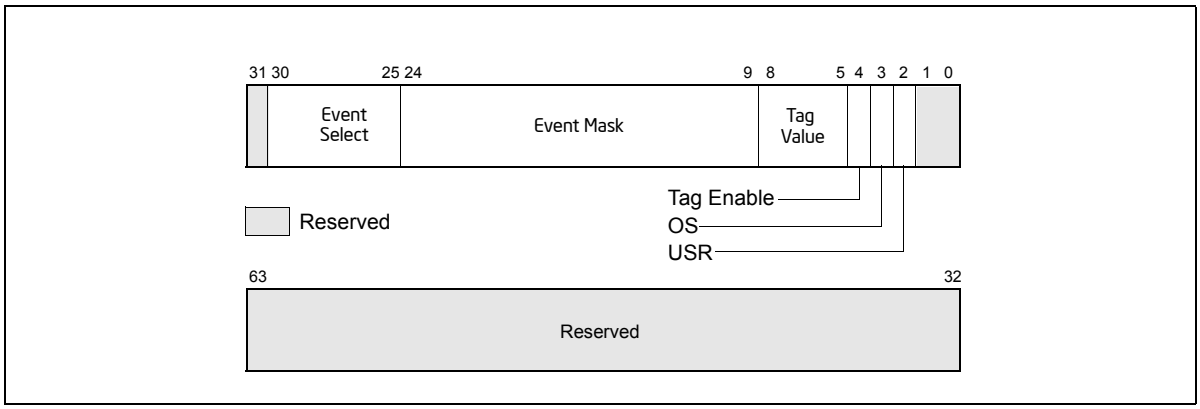

**Figure 18-37. Event Selection Control Register (ESCR) for Pentium 4 and Intel Xeon Processors without Intel HT Technology Support**

- **Tag enable, bit 4 —** When set, enables tagging of μops to assist in at-retirement event counting; when clear, disables tagging. See Section 18.13.6, "At-Retirement Counting."
- **Tag value field, bits 5 through 8 —** Selects a tag value to associate with a μop to assist in at-retirement event counting.
- **Event mask field, bits 9 through 24 —** Selects events to be counted from the event class selected with the event select field.
- **Event select field, bits 25 through 30) —** Selects a class of events to be counted. The events within this class that are counted are selected with the event mask field.

When setting up an ESCR, the event select field is used to select a specific class of events to count, such as retired branches. The event mask field is then used to select one or more of the specific events within the class to be counted. For example, when counting retired branches, four different events can be counted: branch not taken predicted, branch not taken mispredicted, branch taken predicted, and branch taken mispredicted. The OS and USR flags allow counts to be enabled for events that occur when operating system code and/or application code are being executed. If neither the OS nor USR flag is set, no events will be counted.

The ESCRs are initialized to all 0s on reset. The flags and fields of an ESCR are configured by writing to the ESCR using the WRMSR instruction. Table 18-45 gives the addresses of the ESCR MSRs.

Writing to an ESCR MSR does not enable counting with its associated performance counter; it only selects the event or events to be counted. The CCCR for the selected performance counter must also be configured. Configuration of the CCCR includes selecting the ESCR and enabling the counter.

## 18.13.2 Performance Counters

The performance counters in conjunction with the counter configuration control registers (CCCRs) are used for filtering and counting the events selected by the ESCRs. The Pentium 4 and Intel Xeon processors provide 18 performance counters organized into 9 pairs. A pair of performance counters is associated with a particular subset of events and ESCR's (see Table 18-45). The counter pairs are partitioned into four groups:

- The BPU group, includes two performance counter pairs:
  - MSR_BPU_COUNTER0 and MSR_BPU_COUNTER1.
  - MSR_BPU_COUNTER2 and MSR_BPU_COUNTER3.

- The MS group, includes two performance counter pairs:
  - MSR_MS_COUNTER0 and MSR_MS_COUNTER1.
  - MSR_MS_COUNTER2 and MSR_MS_COUNTER3.
- The FLAME group, includes two performance counter pairs:
  - MSR_FLAME_COUNTER0 and MSR_FLAME_COUNTER1.
  - MSR_FLAME_COUNTER2 and MSR_FLAME_COUNTER3.
- The IQ group, includes three performance counter pairs:
  - MSR_IQ_COUNTER0 and MSR_IQ_COUNTER1.
  - MSR_IQ_COUNTER2 and MSR_IQ_COUNTER3.
  - MSR_IQ_COUNTER4 and MSR_IQ_COUNTER5.

The MSR_IQ_COUNTER4 counter in the IQ group provides support for the PEBS.

Alternate counters in each group can be cascaded: the first counter in one pair can start the first counter in the second pair and vice versa. A similar cascading is possible for the second counters in each pair. For example, within the BPU group of counters, MSR_BPU_COUNTER0 can start MSR_BPU_COUNTER2 and vice versa, and MSR_BPU_COUNTER1 can start MSR_BPU_COUNTER3 and vice versa (see Section 18.13.5.6, "Cascading Counters"). The cascade flag in the CCCR register for the performance counter enables the cascading of counters.

Each performance counter is 40-bits wide (see Figure 18-38). The RDPMC instruction has been enhanced in the Pentium 4 and Intel Xeon processors to allow reading of either the full counter-width (40-bits) or the low 32-bits of the counter. Reading the low 32-bits is faster than reading the full counter width and is appropriate in situations where the count is small enough to be contained in 32 bits.

The RDPMC instruction can be used by programs or procedures running at any privilege level and in virtual-8086 mode to read these counters. The PCE flag in control register CR4 (bit 8) allows the use of this instruction to be restricted to only programs and procedures running at privilege level 0.

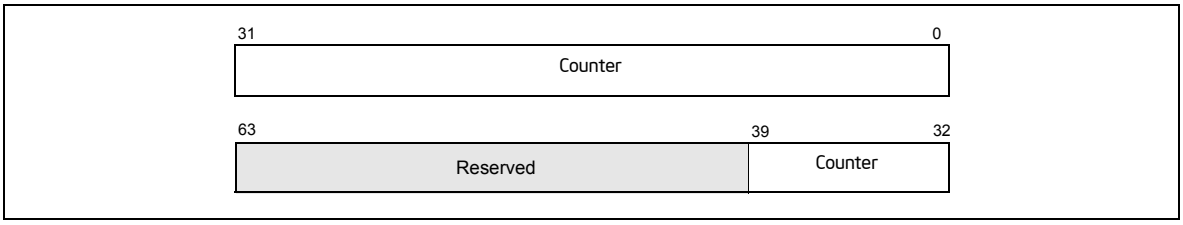

**Figure 18-38. Performance Counter (Pentium 4 and Intel Xeon Processors)**

The RDPMC instruction is not serializing or ordered with other instructions. Thus, it does not necessarily wait until all previous instructions have been executed before reading the counter. Similarly, subsequent instructions may begin execution before the RDPMC instruction operation is performed.

Only the operating system, executing at privilege level 0, can directly manipulate the performance counters, using the RDMSR and WRMSR instructions. A secure operating system would clear the PCE flag during system initialization to disable direct user access to the performance-monitoring counters, but provide a user-accessible programming interface that emulates the RDPMC instruction.

Some uses of the performance counters require the counters to be preset before counting begins (that is, before the counter is enabled). This can be accomplished by writing to the counter using the WRMSR instruction. To set a counter to a specified number of counts before overflow, enter a 2s complement negative integer in the counter. The counter will then count from the preset value up to -1 and overflow. Writing to a performance counter in a Pentium 4 or Intel Xeon processor with the WRMSR instruction causes all 40 bits of the counter to be written.

### 18.13.3 CCCR MSRs

Each of the 18 performance counters in a Pentium 4 or Intel Xeon processor has one CCCR MSR associated with it (see Table 18-45). The CCCRs control the filtering and counting of events as well as interrupt generation. Figure 18-39 shows the layout of an CCCR MSR. The functions of the flags and fields are as follows:

- **Enable flag, bit 12 —** When set, enables counting; when clear, the counter is disabled. This flag is cleared on reset.
- **ESCR select field, bits 13 through 15 —** Identifies the ESCR to be used to select events to be counted with the counter associated with the CCCR.
- **Compare flag, bit 18 —** When set, enables filtering of the event count; when clear, disables filtering. The filtering method is selected with the threshold, complement, and edge flags.
- **Complement flag, bit 19 —** Selects how the incoming event count is compared with the threshold value. When set, event counts that are less than or equal to the threshold value result in a single count being delivered to the performance counter; when clear, counts greater than the threshold value result in a count being delivered to the performance counter (see Section 18.13.5.2, "Filtering Events"). The complement flag is not active unless the compare flag is set.
- **Threshold field, bits 20 through 23 —** Selects the threshold value to be used for comparisons. The processor examines this field only when the compare flag is set, and uses the complement flag setting to determine the type of threshold comparison to be made. The useful range of values that can be entered in this field depend on the type of event being counted (see Section 18.13.5.2, "Filtering Events").
- **Edge flag, bit 24 —** When set, enables rising edge (false-to-true) edge detection of the threshold comparison output for filtering event counts; when clear, rising edge detection is disabled. This flag is active only when the compare flag is set.

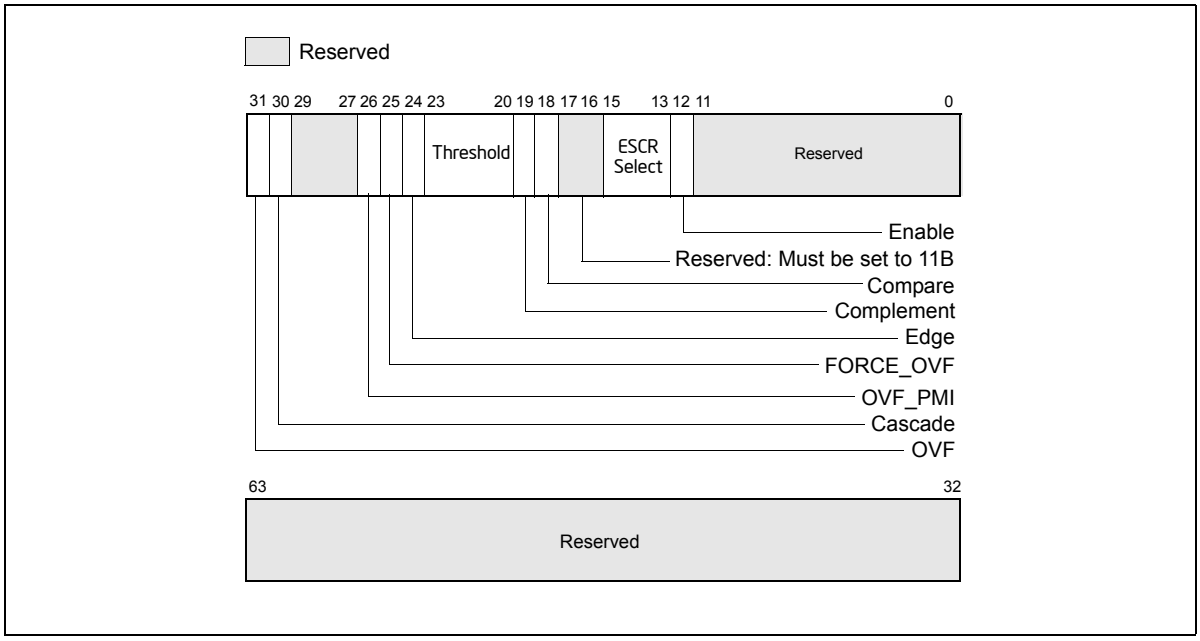

Figure 18-39. Counter Configuration Control Register (CCCR)

- **FORCE_OVF flag, bit 25 —** When set, forces a counter overflow on every counter increment; when clear, overflow only occurs when the counter actually overflows.
- **OVF_PMI flag, bit 26 —** When set, causes a performance monitor interrupt (PMI) to be generated when the counter overflows occurs; when clear, disables PMI generation. Note that the PMI is generated on the next event count after the counter has overflowed.
- **Cascade flag, bit 30 —** When set, enables counting on one counter of a counter pair when its alternate counter in the other the counter pair in the same counter group overflows (see Section 18.13.2, "Performance Counters," for further details); when clear, disables cascading of counters.

- **OVF flag, bit 31 —** Indicates that the counter has overflowed when set. This flag is a sticky flag that must be explicitly cleared by software.

The CCCRs are initialized to all 0s on reset.

The events that an enabled performance counter actually counts are selected and filtered by the following flags and fields in the ESCR and CCCR registers and in the qualification order given:

1. The event select and event mask fields in the ESCR select a class of events to be counted and one or more event types within the class, respectively.
2. The OS and USR flags in the ESCR selected the privilege levels at which events will be counted.
3. The ESCR select field of the CCCR selects the ESCR. Since each counter has several ESCRs associated with it, one ESCR must be chosen to select the classes of events that may be counted.
4. The compare and complement flags and the threshold field of the CCCR select an optional threshold to be used in qualifying an event count.
5. The edge flag in the CCCR allows events to be counted only on rising-edge transitions.

The qualification order in the above list implies that the filtered output of one "stage" forms the input for the next. For instance, events filtered using the privilege level flags can be further qualified by the compare and complement flags and the threshold field, and an event that matched the threshold criteria, can be further qualified by edge detection.

The uses of the flags and fields in the CCCRs are discussed in greater detail in Section 18.13.5, "Programming the Performance Counters for Non-Retirement Events."

### 18.13.4 Debug Store (DS) Mechanism

The debug store (DS) mechanism was introduced in the Pentium 4 and Intel Xeon processors to allow various types of information to be collected in memory-resident buffers for use in debugging and tuning programs. For the Pentium 4 and Intel Xeon processors, the DS mechanism is used to collect two types of information: branch records and precise event-based sampling (PEBS) records. The availability of the DS mechanism in a processor is indicated with the DS feature flag (bit 21) returned by the CPUID instruction.

See Section 17.4.5, "Branch Trace Store (BTS)," and Section 18.13.7, "Precise Event-Based Sampling (PEBS)," for a description of these facilities. Records collected with the DS mechanism are saved in the DS save area. See Section 17.4.9, "BTS and DS Save Area."

### 18.13.5 Programming the Performance Counters for Non-Retirement Events

The basic steps to program a performance counter and to count events include the following:

1. Select the event or events to be counted.
2. For each event, select an ESCR that supports the event using the values in the ESCR restrictions row in Table 19-23, Chapter 19.
3. Match the CCCR Select value and ESCR name in Table 19-23 to a value listed in Table 18-45; select a CCCR and performance counter.
4. Set up an ESCR for the specific event or events to be counted and the privilege levels at which the are to be counted.
5. Set up the CCCR for the performance counter by selecting the ESCR and the desired event filters.
6. Set up the CCCR for optional cascading of event counts, so that when the selected counter overflows its alternate counter starts.
7. Set up the CCCR to generate an optional performance monitor interrupt (PMI) when the counter overflows. If PMI generation is enabled, the local APIC must be set up to deliver the interrupt to the processor and a handler for the interrupt must be in place.
8. Enable the counter to begin counting.

### 18.13.5.1 Selecting Events to Count

Table 19-24 in Chapter 19 lists a set of at-retirement events for the Pentium 4 and Intel Xeon processors. For each event listed in Table 19-24, setup information is provided. Table 18-46 gives an example of one of the events.

**Table 18-46. Event Example**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| branch_retired | | | Counts the retirement of a branch. Specify one or more mask bits to select any combination of branch taken, not-taken, predicted and mispredicted. |
| | ESCR restrictions | MSR_CRU_ESCR2<br>MSR_CRU_ESCR3 | See Table 15-3 for the addresses of the ESCR MSRs |
| | Counter numbers per ESCR | ESCR2: 12, 13, 16<br>ESCR3: 14, 15, 17 | The counter numbers associated with each ESCR are provided. The performance counters and corresponding CCCRs can be obtained from Table 15-3. |
| | ESCR Event Select | 06H | ESCR[31:25] |
| | ESCR Event Mask | <br>Bit 0: MMNP<br>1: MMNM<br>2: MMTP<br>3: MMTM | ESCR[24:9],<br>Branch Not-taken Predicted,<br>Branch Not-taken Mispredicted,<br>Branch Taken Predicted,<br>Branch Taken Mispredicted. |
| | CCCR Select | 05H | CCCR[15:13] |
| | Event Specific Notes | | P6: EMON_BR_INST_RETIRED |
| | Can Support PEBS | No | |
| | Requires Additional MSRs for Tagging | No | |

For Table 19-23 and Table 19-24, Chapter 19, the name of the event is listed in the Event Name column and parameters that define the event and other information are listed in the Event Parameters column. The Parameter Value and Description columns give specific parameters for the event and additional description information. Entries in the Event Parameters column are described below.

- **ESCR restrictions —** Lists the ESCRs that can be used to program the event. Typically only one ESCR is needed to count an event.
- **Counter numbers per ESCR —** Lists which performance counters are associated with each ESCR. Table 18-45 gives the name of the counter and CCCR for each counter number. Typically only one counter is needed to count the event.
- **ESCR event select —** Gives the value to be placed in the event select field of the ESCR to select the event.
- **ESCR event mask —** Gives the value to be placed in the Event Mask field of the ESCR to select sub-events to be counted. The parameter value column defines the documented bits with relative bit position offset starting from 0, where the absolute bit position of relative offset 0 is bit 9 of the ESCR. All undocumented bits are reserved and should be set to 0.
- **CCCR select —** Gives the value to be placed in the ESCR select field of the CCCR associated with the counter to select the ESCR to be used to define the event. This value is not the address of the ESCR; it is the number of the ESCR from the Number column in Table 18-45.
- **Event specific notes —** Gives additional information about the event, such as the name of the same or a similar event defined for the P6 family processors.
- **Can support PEBS —** Indicates if PEBS is supported for the event (only supplied for at-retirement events listed in Table 19-24.)
- **Requires additional MSR for tagging —** Indicates which if any additional MSRs must be programmed to count the events (only supplied for the at-retirement events listed in Table 19-24.)

**NOTE**

The performance-monitoring events listed in Chapter 19, "Performance-Monitoring Events," are intended to be used as guides for performance tuning. The counter values reported are not guaranteed to be absolutely accurate and should be used as a relative guide for tuning. Known discrepancies are documented where applicable.

The following procedure shows how to set up a performance counter for basic counting; that is, the counter is set up to count a specified event indefinitely, wrapping around whenever it reaches its maximum count. This procedure is continued through the following four sections.

Using information in Table 19-23, Chapter 19, an event to be counted can be selected as follows:

1. Select the event to be counted.
2. Select the ESCR to be used to select events to be counted from the ESCRs field.
3. Select the number of the counter to be used to count the event from the Counter Numbers Per ESCR field.
4. Determine the name of the counter and the CCCR associated with the counter, and determine the MSR addresses of the counter, CCCR, and ESCR from Table 18-45.
5. Use the WRMSR instruction to write the ESCR Event Select and ESCR Event Mask values into the appropriate fields in the ESCR. At the same time set or clear the USR and OS flags in the ESCR as desired.
6. Use the WRMSR instruction to write the CCCR Select value into the appropriate field in the CCCR.

**NOTE**

Typically all the fields and flags of the CCCR will be written with one WRMSR instruction; however, in this procedure, several WRMSR writes are used to more clearly demonstrate the uses of the various CCCR fields and flags.

This setup procedure is continued in the next section, Section 18.13.5.2, "Filtering Events."

### 18.13.5.2 Filtering Events

Each counter receives up to 4 input lines from the processor hardware from which it is counting events. The counter treats these inputs as binary inputs (input 0 has a value of 1, input 1 has a value of 2, input 3 has a value of 4, and input 3 has a value of 8). When a counter is enabled, it adds this binary input value to the counter value on each clock cycle. For each clock cycle, the value added to the counter can then range from 0 (no event) to 15.

For many events, only the 0 input line is active, so the counter is merely counting the clock cycles during which the 0 input is asserted. However, for some events two or more input lines are used. Here, the counters threshold setting can be used to filter events. The compare, complement, threshold, and edge fields control the filtering of counter increments by input value.

If the compare flag is set, then a "greater than" or a "less than or equal to" comparison of the input value vs. a threshold value can be made. The complement flag selects "less than or equal to" (flag set) or "greater than" (flag clear). The threshold field selects a threshold value of from 0 to 15. For example, if the complement flag is cleared and the threshold field is set to 6, than any input value of 7 or greater on the 4 inputs to the counter will cause the counter to be incremented by 1, and any value less than 7 will cause an increment of 0 (or no increment) of the counter. Conversely, if the complement flag is set, any value from 0 to 6 will increment the counter and any value from 7 to 15 will not increment the counter. Note that when a threshold condition has been satisfied, the input to the counter is always 1, not the input value that is presented to the threshold filter.

The edge flag provides further filtering of the counter inputs when a threshold comparison is being made. The edge flag is only active when the compare flag is set. When the edge flag is set, the resulting output from the threshold filter (a value of 0 or 1) is used as an input to the edge filter. Each clock cycle, the edge filter examines the last and current input values and sends a count to the counter only when it detects a "rising edge" event; that is, a false-to-true transition. Figure 18-40 illustrates rising edge filtering.

The following procedure shows how to configure a CCCR to filter events using the threshold filter and the edge filter. This procedure is a continuation of the setup procedure introduced in Section 18.13.5.1, "Selecting Events to Count."

7. (Optional) To set up the counter for threshold filtering, use the WRMSR instruction to write values in the CCCR compare and complement flags and the threshold field:
   — Set the compare flag.
   — Set or clear the complement flag for less than or equal to or greater than comparisons, respectively.
   — Enter a value from 0 to 15 in the threshold field.
8. (Optional) Select rising edge filtering by setting the CCCR edge flag.

This setup procedure is continued in the next section, Section 18.13.5.3, "Starting Event Counting."

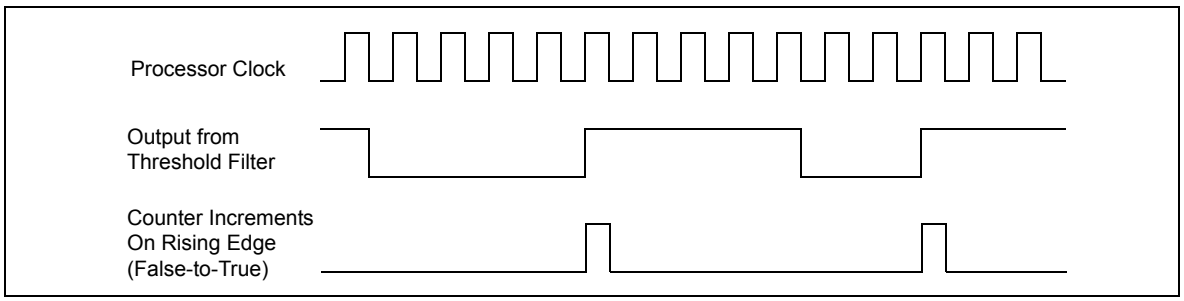

**Figure 18-40. Effects of Edge Filtering**

### 18.13.5.3 Starting Event Counting

Event counting by a performance counter can be initiated in either of two ways. The typical way is to set the enable flag in the counter's CCCR. Following the instruction to set the enable flag, event counting begins and continues until it is stopped (see Section 18.13.5.5, "Halting Event Counting").

The following procedural step shows how to start event counting. This step is a continuation of the setup procedure introduced in Section 18.13.5.2, "Filtering Events."

9. To start event counting, use the WRMSR instruction to set the CCCR enable flag for the performance counter.

This setup procedure is continued in the next section, Section 18.13.5.4, "Reading a Performance Counter's Count."

The second way that a counter can be started by using the cascade feature. Here, the overflow of one counter automatically starts its alternate counter (see Section 18.13.5.6, "Cascading Counters").

### 18.13.5.4 Reading a Performance Counter's Count

The Pentium 4 and Intel Xeon processors' performance counters can be read using either the RDPMC or RDMSR instructions. The enhanced functions of the RDPMC instruction (including fast read) are described in Section 18.13.2, "Performance Counters." These instructions can be used to read a performance counter while it is counting or when it is stopped.

The following procedural step shows how to read the event counter. This step is a continuation of the setup procedure introduced in Section 18.13.5.3, "Starting Event Counting."

10. To read a performance counters current event count, execute the RDPMC instruction with the counter number obtained from Table 18-45 used as an operand.

This setup procedure is continued in the next section, Section 18.13.5.5, "Halting Event Counting."

### 18.13.5.5 Halting Event Counting

After a performance counter has been started (enabled), it continues counting indefinitely. If the counter overflows (goes one count past its maximum count), it wraps around and continues counting. When the counter wraps around, it sets its OVF flag to indicate that the counter has overflowed. The OVF flag is a sticky flag that indicates that the counter has overflowed at least once since the OVF bit was last cleared.

To halt counting, the CCCR enable flag for the counter must be cleared.

The following procedural step shows how to stop event counting. This step is a continuation of the setup procedure introduced in Section 18.13.5.4, "Reading a Performance Counter's Count."

11. To stop event counting, execute a WRMSR instruction to clear the CCCR enable flag for the performance counter.

To halt a cascaded counter (a counter that was started when its alternate counter overflowed), either clear the Cascade flag in the cascaded counter's CCCR MSR or clear the OVF flag in the alternate counter's CCCR MSR.

### 18.13.5.6 Cascading Counters

As described in Section 18.13.2, "Performance Counters," eighteen performance counters are implemented in pairs. Nine pairs of counters and associated CCCRs are further organized as four blocks: BPU, MS, FLAME, and IQ (see Table 18-45). The first three blocks contain two pairs each. The IQ block contains three pairs of counters (12 through 17) with associated CCCRs (MSR_IQ_CCCR0 through MSR_IQ_CCCR5).

The first 8 counter pairs (0 through 15) can be programmed using ESCRs to detect performance monitoring events. Pairs of ESCRs in each of the four blocks allow many different types of events to be counted. The cascade flag in the CCCR MSR allows nested monitoring of events to be performed by cascading one counter to a second counter located in another pair in the same block (see Figure 18-39 for the location of the flag).

Counters 0 and 1 form the first pair in the BPU block. Either counter 0 or 1 can be programmed to detect an event via MSR_MO B_ESCR0. Counters 0 and 2 can be cascaded in any order, as can counters 1 and 3. It's possible to set up 4 counters in the same block to cascade on two pairs of independent events. The pairing described also applies to subsequent blocks. Since the IQ PUB has two extra counters, cascading operates somewhat differently if 16 and 17 are involved. In the IQ block, counter 16 can only be cascaded from counter 14 (not from 12); counter 14 cannot be cascaded from counter 16 using the CCCR cascade bit mechanism. Similar restrictions apply to counter 17.

#### Example 18-1. Counting Events

Assume a scenario where counter X is set up to count 200 occurrences of event A; then counter Y is set up to count 400 occurrences of event B. Each counter is set up to count a specific event and overflow to the next counter. In the above example, counter X is preset for a count of -200 and counter Y for a count of -400; this setup causes the counters to overflow on the 200th and 400th counts respectively.

Continuing this scenario, counter X is set up to count indefinitely and wraparound on overflow. This is described in the basic performance counter setup procedure that begins in Section 18.13.5.1, "Selecting Events to Count." Counter Y is set up with the cascade flag in its associated CCCR MSR set to 1 and its enable flag set to 0.

To begin the nested counting, the enable bit for the counter X is set. Once enabled, counter X counts until it overflows. At this point, counter Y is automatically enabled and begins counting. Thus counter X overflows after 200 occurrences of event A. Counter Y then starts, counting 400 occurrences of event B before overflowing. When performance counters are cascaded, the counter Y would typically be set up to generate an interrupt on overflow. This is described in Section 18.13.5.8, "Generating an Interrupt on Overflow."

The cascading counters mechanism can be used to count a single event. The counting begins on one counter then continues on the second counter after the first counter overflows. This technique doubles the number of event counts that can be recorded, since the contents of the two counters can be added together.

### 18.13.5.7 EXTENDED CASCADING

Extended cascading is a model-specific feature in the Intel NetBurst microarchitecture. The feature is available to Pentium 4 and Xeon processor family with family encoding of 15 and model encoding greater than or equal to 2.

This feature uses bit 11 in CCCRs associated with the IQ block. See Table 18-47.

**Table 18-47. CCR Names and Bit Positions**

| CCCR Name:Bit Position | Bit Name | Description |
|---|---|---|
| MSR_IQ_CCCR1\|2:11 | Reserved | |
| MSR_IQ_CCCR0:11 | CASCNT4INTO0 | Allow counter 4 to cascade into counter 0 |
| MSR_IQ_CCCR3:11 | CASCNT5INTO3 | Allow counter 5 to cascade into counter 3 |
| MSR_IQ_CCCR4:11 | CASCNT5INTO4 | Allow counter 5 to cascade into counter 4 |
| MSR_IQ_CCCR5:11 | CASCNT4INTO5 | Allow counter 4 to cascade into counter 5 |

The extended cascading feature can be adapted to the sampling usage model for performance monitoring. However, it is known that performance counters do not generate PMI in cascade mode or extended cascade mode due to an erratum. This erratum applies to Pentium 4 and Intel Xeon processors with model encoding of 2. For Pentium 4 and Intel Xeon processors with model encoding of 0 and 1, the erratum applies to processors with stepping encoding greater than 09H.

Counters 16 and 17 in the IQ block are frequently used in precise event-based sampling or at-retirement counting of events indicating a stalled condition in the pipeline. Neither counter 16 or 17 can initiate the cascading of counter pairs using the cascade bit in a CCCR.

Extended cascading permits performance monitoring tools to use counters 16 and 17 to initiate cascading of two counters in the IQ block. Extended cascading from counter 16 and 17 is conceptually similar to cascading other counters, but instead of using CASCADE bit of a CCCR, one of the four CASCNTxINTOy bits is used.

#### Example 18-2. Scenario for Extended Cascading

A usage scenario for extended cascading is to sample instructions retired on logical processor 1 after the first 4096 instructions retired on logical processor 0. A procedure to program extended cascading in this scenario is outlined below:

1. Write the value 0 to counter 12.
2. Write the value 04000603H to MSR_CRU_ESCR0 (corresponding to selecting the NBOGNTAG and NBOGTAG event masks with qualification restricted to logical processor 1).
3. Write the value 04038800H to MSR_IQ_CCCR0. This enables CASCNT4INTO0 and OVF_PMI. An ISR can sample on instruction addresses in this case (do not set ENABLE, or CASCADE).
4. Write the value FFFFF000H into counter 16.1.
5. Write the value 0400060CH to MSR_CRU_ESCR2 (corresponding to selecting the NBOGNTAG and NBOGTAG event masks with qualification restricted to logical processor 0).
6. Write the value 00039000H to MSR_IQ_CCCR4 (set ENABLE bit, but not OVF_PMI).

Another use for cascading is to locate stalled execution in a multithreaded application. Assume MOB replays in thread B cause thread A to stall. Getting a sample of the stalled execution in this scenario could be accomplished by:

1. Set up counter B to count MOB replays on thread B.
2. Set up counter A to count resource stalls on thread A; set its force overflow bit and the appropriate CASCNTxINTOy bit.
3. Use the performance monitoring interrupt to capture the program execution data of the stalled thread.

### 18.13.5.8 Generating an Interrupt on Overflow

Any performance counter can be configured to generate a performance monitor interrupt (PMI) if the counter overflows. The PMI interrupt service routine can then collect information about the state of the processor or program

when overflow occurred. This information can then be used with a tool like the Intel® VTune™ Performance Analyzer to analyze and tune program performance.

To enable an interrupt on counter overflow, the OVR_PMI flag in the counter's associated CCCR MSR must be set. When overflow occurs, a PMI is generated through the local APIC. (Here, the performance counter entry in the local vector table [LVT] is set up to deliver the interrupt generated by the PMI to the processor.)

The PMI service routine can use the OVF flag to determine which counter overflowed when multiple counters have been configured to generate PMIs. Also, note that these processors mask PMIs upon receiving an interrupt. Clear this condition before leaving the interrupt handler.

When generating interrupts on overflow, the performance counter being used should be preset to value that will cause an overflow after a specified number of events are counted plus 1. The simplest way to select the preset value is to write a negative number into the counter, as described in Section 18.13.5.6, "Cascading Counters." Here, however, if an interrupt is to be generated after 100 event counts, the counter should be preset to minus 100 plus 1 (-100 + 1), or -99. The counter will then overflow after it counts 99 events and generate an interrupt on the next (100th) event counted. The difference of 1 for this count enables the interrupt to be generated immediately after the selected event count has been reached, instead of waiting for the overflow to be propagation through the counter.

Because of latency in the microarchitecture between the generation of events and the generation of interrupts on overflow, it is sometimes difficult to generate an interrupt close to an event that caused it. In these situations, the FORCE_OVF flag in the CCCR can be used to improve reporting. Setting this flag causes the counter to overflow on every counter increment, which in turn triggers an interrupt after every counter increment.

### 18.13.5.9 Counter Usage Guideline

There are some instances where the user must take care to configure counting logic properly, so that it is not powered down. To use any ESCR, even when it is being used just for tagging, (any) one of the counters that the particular ESCR (or its paired ESCR) can be connected to should be enabled. If this is not done, 0 counts may result. Likewise, to use any counter, there must be some event selected in a corresponding ESCR (other than no_event, which generally has a select value of 0).

## 18.13.6 At-Retirement Counting

At-retirement counting provides a means counting only events that represent work committed to architectural state and ignoring work that was performed speculatively and later discarded.

The Intel NetBurst microarchitecture used in the Pentium 4 and Intel Xeon processors performs many speculative activities in an attempt to increase effective processing speeds. One example of this speculative activity is branch prediction. The Pentium 4 and Intel Xeon processors typically predict the direction of branches and then decode and execute instructions down the predicted path in anticipation of the actual branch decision. When a branch misprediction occurs, the results of instructions that were decoded and executed down the mispredicted path are canceled. If a performance counter was set up to count all executed instructions, the count would include instructions whose results were canceled as well as those whose results committed to architectural state.

To provide finer granularity in event counting in these situations, the performance monitoring facilities provided in the Pentium 4 and Intel Xeon processors provide a mechanism for tagging events and then counting only those tagged events that represent committed results. This mechanism is called "at-retirement counting."

Tables 19-24 through 19-28 list predefined at-retirement events and event metrics that can be used to for tagging events when using at retirement counting. The following terminology is used in describing at-retirement counting:

- **Bogus, non-bogus, retire —** In at-retirement event descriptions, the term "bogus" refers to instructions or μops that must be canceled because they are on a path taken from a mispredicted branch. The terms "retired" and "non-bogus" refer to instructions or μops along the path that results in committed architectural state changes as required by the program being executed. Thus instructions and μops are either bogus or non-bogus, but not both. Several of the Pentium 4 and Intel Xeon processors' performance monitoring events (such as, Instruction_Retired and Uops_Retired in Table 19-24) can count instructions or μops that are retired based on the characterization of bogus" versus non-bogus.

- **Tagging —** Tagging is a means of marking μops that have encountered a particular performance event so they can be counted at retirement. During the course of execution, the same event can happen more than once per μop and a direct count of the event would not provide an indication of how many μops encountered that event.

  The tagging mechanisms allow a μop to be tagged once during its lifetime and thus counted once at retirement. The retired suffix is used for performance metrics that increment a count once per μop, rather than once per event. For example, a μop may encounter a cache miss more than once during its life time, but a "Miss Retired" metric (that counts the number of retired μops that encountered a cache miss) will increment only once for that μop. A "Miss Retired" metric would be useful for characterizing the performance of the cache hierarchy for a particular instruction sequence. Details of various performance metrics and how these can be constructed using the Pentium 4 and Intel Xeon processors performance events are provided in the *Intel Pentium 4 Processor Optimization Reference Manual* (see Section 1.4, "Related Literature").
- **Replay —** To maximize performance for the common case, the Intel NetBurst microarchitecture aggressively schedules μops for execution before all the conditions for correct execution are guaranteed to be satisfied. In the event that all of these conditions are not satisfied, μops must be reissued. The mechanism that the Pentium 4 and Intel Xeon processors use for this reissuing of μops is called replay. Some examples of replay causes are cache misses, dependence violations, and unforeseen resource constraints. In normal operation, some number of replays is common and unavoidable. An excessive number of replays is an indication of a performance problem.
- **Assist —** When the hardware needs the assistance of microcode to deal with some event, the machine takes an assist. One example of this is an underflow condition in the input operands of a floating-point operation. The hardware must internally modify the format of the operands in order to perform the computation. Assists clear the entire machine of μops before they begin and are costly.

### 18.13.6.1 Using At-Retirement Counting

The Pentium 4 and Intel Xeon processors allow counting both events and μops that encountered a specified event. For a subset of the at-retirement events listed in Table 19-24, a μop may be tagged when it encounters that event. The tagging mechanisms can be used in non-precise event-based sampling, and a subset of these mechanisms can be used in PEBS. There are four independent tagging mechanisms, and each mechanism uses a different event to count μops tagged with that mechanism:

- **Front-end tagging —** This mechanism pertains to the tagging of μops that encountered front-end events (for example, trace cache and instruction counts) and are counted with the Front_end_event event
- **Execution tagging —** This mechanism pertains to the tagging of μops that encountered execution events (for example, instruction types) and are counted with the Execution_Event event.
- **Replay tagging —** This mechanism pertains to tagging of μops whose retirement is replayed (for example, a cache miss) and are counted with the Replay_event event. Branch mispredictions are also tagged with this mechanism.
- **No tags —** This mechanism does not use tags. It uses the Instr_retired and the Uops_ retired events.

Each tagging mechanism is independent from all others; that is, a μop that has been tagged using one mechanism will not be detected with another mechanism's tagged-μop detector. For example, if μops are tagged using the front-end tagging mechanisms, the Replay_event will not count those as tagged μops unless they are also tagged using the replay tagging mechanism. However, execution tags allow up to four different types of μops to be counted at retirement through execution tagging.

The independence of tagging mechanisms does not hold when using PEBS. When using PEBS, only one tagging mechanism should be used at a time.

Certain kinds of μops that cannot be tagged, including I/O, uncacheable and locked accesses, returns, and far transfers.

Table 19-24 lists the performance monitoring events that support at-retirement counting: specifically the Front_end_event, Execution_event, Replay_event, Inst_retired and Uops_retired events. The following sections describe the tagging mechanisms for using these events to tag μop and count tagged μops.

### 18.13.6.2 Tagging Mechanism for Front_end_event

The Front_end_event counts μops that have been tagged as encountering any of the following events:

- **μop decode events —** Tagging μops for μop decode events requires specifying bits in the ESCR associated with the performance-monitoring event, Uop_type.
- **Trace cache events —** Tagging μops for trace cache events may require specifying certain bits in the MSR_TC_PRECISE_EVENT MSR (see Table 19-26).

Table 19-24 describes the Front_end_event and Table 19-26 describes metrics that are used to set up a Front_end_event count.

The MSRs specified in the Table 19-24 that are supported by the front-end tagging mechanism must be set and one or both of the NBOGUS and BOGUS bits in the Front_end_event event mask must be set to count events. None of the events currently supported requires the use of the MSR_TC_PRECISE_EVENT MSR.

### 18.13.6.3 Tagging Mechanism For Execution_event

Table 19-24 describes the Execution_event and Table 19-27 describes metrics that are used to set up an Execution_event count.

The execution tagging mechanism differs from other tagging mechanisms in how it causes tagging. One *upstream* ESCR is used to specify an event to detect and to specify a tag value (bits 5 through 8) to identify that event. A second *downstream* ESCR is used to detect μops that have been tagged with that tag value identifier using Execution_event for the event selection.

The upstream ESCR that counts the event must have its tag enable flag (bit 4) set and must have an appropriate tag value mask entered in its tag value field. The 4-bit tag value mask specifies which of tag bits should be set for a particular μop. The value selected for the tag value should coincide with the event mask selected in the downstream ESCR. For example, if a tag value of 1 is set, then the event mask of NBOGUS0 should be enabled, correspondingly in the downstream ESCR. The downstream ESCR detects and counts tagged μops. The normal (not tag value) mask bits in the downstream ESCR specify which tag bits to count. If any one of the tag bits selected by the mask is set, the related counter is incremented by one. This mechanism is summarized in the Table 19-27 metrics that are supported by the execution tagging mechanism. The tag enable and tag value bits are irrelevant for the downstream ESCR used to select the Execution_event.

The four separate tag bits allow the user to simultaneously but distinctly count up to four execution events at retirement. (This applies for non-precise event-based sampling. There are additional restrictions for PEBS as noted in Section 18.13.7.3, "Setting Up the PEBS Buffer.") It is also possible to detect or count combinations of events by setting multiple tag value bits in the upstream ESCR or multiple mask bits in the downstream ESCR. For example, use a tag value of 3H in the upstream ESCR and use NBOGUS0/NBOGUS1 in the downstream ESCR event mask.

### 18.13.6.4 Tagging Mechanism for Replay_event

Table 19-24 describes the Replay_event and Table 19-28 describes metrics that are used to set up an Replay_event count.

The replay mechanism enables tagging of μops for a subset of all replays before retirement. Use of the replay mechanism requires selecting the type of μop that may experience the replay in the MSR_PEBS_MATRIX_VERT MSR and selecting the type of event in the MSR_PEBS_ENABLE MSR. Replay tagging must also be enabled with the UOP_Tag flag (bit 24) in the MSR_PEBS_ENABLE MSR.

The Table 19-28 lists the metrics that are support the replay tagging mechanism and the at-retirement events that use the replay tagging mechanism, and specifies how the appropriate MSRs need to be configured. The replay tags defined in Table A-5 also enable Precise Event-Based Sampling (PEBS, see Section 15.9.8). Each of these replay tags can also be used in normal sampling by not setting Bit 24 nor Bit 25 in IA_32_PEBS_ENABLE_MSR. Each of these metrics requires that the Replay_Event (see Table 19-24) be used to count the tagged μops.

## 18.13.7 Precise Event-Based Sampling (PEBS)

The debug store (DS) mechanism in processors based on Intel NetBurst microarchitecture allow two types of information to be collected for use in debugging and tuning programs: PEBS records and BTS records. See Section 17.4.5, "Branch Trace Store (BTS)," for a description of the BTS mechanism.

PEBS permits the saving of precise architectural information associated with one or more performance events in the precise event records buffer, which is part of the DS save area (see Section 17.4.9, "BTS and DS Save Area"). To use this mechanism, a counter is configured to overflow after it has counted a preset number of events. After the counter overflows, the processor copies the current state of the general-purpose and EFLAGS registers and instruction pointer into a record in the precise event records buffer. The processor then resets the count in the performance counter and restarts the counter. When the precise event records buffer is nearly full, an interrupt is generated, allowing the precise event records to be saved. A circular buffer is not supported for precise event records.

PEBS is supported only for a subset of the at-retirement events: Execution_event, Front_end_event, and Replay_event. Also, PEBS can only be carried out using the one performance counter, the MSR_IQ_COUNTER4 MSR.

In processors based on Intel Core microarchitecture, a similar PEBS mechanism is also supported using IA32_PMC0 and IA32_PERFEVTSEL0 MSRs (See Section 18.4.4).

### 18.13.7.1 Detection of the Availability of the PEBS Facilities

The DS feature flag (bit 21) returned by the CPUID instruction indicates (when set) the availability of the DS mechanism in the processor, which supports the PEBS (and BTS) facilities. When this bit is set, the following PEBS facilities are available:

- The PEBS_UNAVAILABLE flag in the IA32_MISC_ENABLE MSR indicates (when clear) the availability of the PEBS facilities, including the MSR_PEBS_ENABLE MSR.
- The enable PEBS flag (bit 24) in the MSR_PEBS_ENABLE MSR allows PEBS to be enabled (set) or disabled (clear).
- The IA32_DS_AREA MSR can be programmed to point to the DS save area.

### 18.13.7.2 Setting Up the DS Save Area

Section 17.4.9.2, "Setting Up the DS Save Area," describes how to set up and enable the DS save area. This procedure is common for PEBS and BTS.

### 18.13.7.3 Setting Up the PEBS Buffer

Only the MSR_IQ_COUNTER4 performance counter can be used for PEBS. Use the following procedure to set up the processor and this counter for PEBS:

1. Set up the precise event buffering facilities. Place values in the precise event buffer base, precise event index, precise event absolute maximum, and precise event interrupt threshold, and precise event counter reset fields of the DS buffer management area (see Figure 17-5) to set up the precise event records buffer in memory.
2. Enable PEBS. Set the Enable PEBS flag (bit 24) in MSR_PEBS_ENABLE MSR.
3. Set up the MSR_IQ_COUNTER4 performance counter and its associated CCCR and one or more ESCRs for PEBS as described in Tables 19-24 through 19-28.

### 18.13.7.4 Writing a PEBS Interrupt Service Routine

The PEBS facilities share the same interrupt vector and interrupt service routine (called the DS ISR) with the non-precise event-based sampling and BTS facilities. To handle PEBS interrupts, PEBS handler code must be included in the DS ISR. See Section 17.4.9.5, "Writing the DS Interrupt Service Routine," for guidelines for writing the DS ISR.

### 18.13.7.5 Other DS Mechanism Implications

The DS mechanism is not available in the SMM. It is disabled on transition to the SMM mode. Similarly the DS mechanism is disabled on the generation of a machine check exception and is cleared on processor RESET and INIT.

The DS mechanism is available in real address mode.

### 18.13.8 Operating System Implications

The DS mechanism can be used by the operating system as a debugging extension to facilitate failure analysis. When using this facility, a 25 to 30 times slowdown can be expected due to the effects of the trace store occurring on every taken branch.

Depending upon intended usage, the instruction pointers that are part of the branch records or the PEBS records need to have an association with the corresponding process. One solution requires the ability for the DS specific operating system module to be chained to the context switch. A separate buffer can then be maintained for each process of interest and the MSR pointing to the configuration area saved and setup appropriately on each context switch.

If the BTS facility has been enabled, then it must be disabled and state stored on transition of the system to a sleep state in which processor context is lost. The state must be restored on return from the sleep state.

It is required that an interrupt gate be used for the DS interrupt as opposed to a trap gate to prevent the generation of an endless interrupt loop.

Pages that contain buffers must have mappings to the same physical address for all processes/logical processors, such that any change to CR3 will not change DS addresses. If this requirement cannot be satisfied (that is, the feature is enabled on a per thread/process basis), then the operating system must ensure that the feature is enabled/disabled appropriately in the context switch code.

## 18.14 PERFORMANCE MONITORING AND INTEL HYPER-THREADING TECHNOLOGY IN PROCESSORS BASED ON INTEL NETBURST® MICROARCHITECTURE

The performance monitoring capability of processors based on Intel NetBurst microarchitecture and supporting Intel Hyper-Threading Technology is similar to that described in Section 18.13. However, the capability is extended so that:

- Performance counters can be programmed to select events qualified by logical processor IDs.
- Performance monitoring interrupts can be directed to a specific logical processor within the physical processor.

The sections below describe performance counters, event qualification by logical processor ID, and special purpose bits in ESCRs/CCCRs. They also describe MSR_PEBS_ENABLE, MSR_PEBS_MATRIX_VERT, and MSR_TC_PRECISE_EVENT.

### 18.14.1 ESCR MSRs

Figure 18-41 shows the layout of an ESCR MSR in processors supporting Intel Hyper-Threading Technology.

The functions of the flags and fields are as follows:

- **T1_USR flag, bit 0 —** When set, events are counted when thread 1 (logical processor 1) is executing at a current privilege level (CPL) of 1, 2, or 3. These privilege levels are generally used by application code and unprotected operating system code.

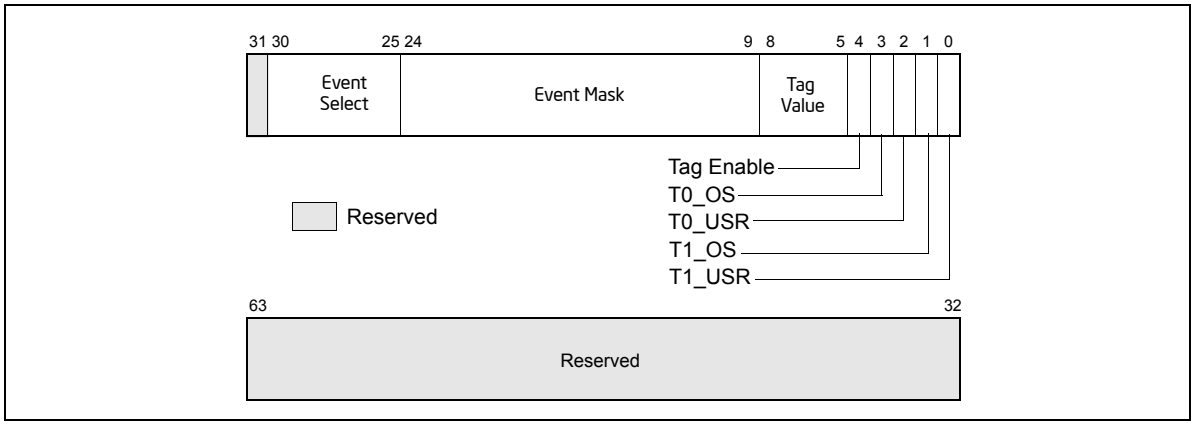

**Figure 18-41. Event Selection Control Register (ESCR) for the Pentium 4 Processor, Intel Xeon Processor and Intel Xeon Processor MP Supporting Hyper-Threading Technology**

- **T1_OS flag, bit 1 —** When set, events are counted when thread 1 (logical processor 1) is executing at CPL of 0. This privilege level is generally reserved for protected operating system code. (When both the T1_OS and T1_USR flags are set, thread 1 events are counted at all privilege levels.)
- **T0_USR flag, bit 2 —** When set, events are counted when thread 0 (logical processor 0) is executing at a CPL of 1, 2, or 3.
- **T0_OS flag, bit 3 —** When set, events are counted when thread 0 (logical processor 0) is executing at CPL of 0. (When both the T0_OS and T0_USR flags are set, thread 0 events are counted at all privilege levels.)
- **Tag enable, bit 4 —** When set, enables tagging of μops to assist in at-retirement event counting; when clear, disables tagging. See Section 18.13.6, "At-Retirement Counting."
- **Tag value field, bits 5 through 8 —** Selects a tag value to associate with a μop to assist in at-retirement event counting.
- **Event mask field, bits 9 through 24 —** Selects events to be counted from the event class selected with the event select field.
- **Event select field, bits 25 through 30) —** Selects a class of events to be counted. The events within this class that are counted are selected with the event mask field.

The T0_OS and T0_USR flags and the T1_OS and T1_USR flags allow event counting and sampling to be specified for a specific logical processor (0 or 1) within an Intel Xeon processor MP (See also: Section 8.4.5, "Identifying Logical Processors in an MP System," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*).

Not all performance monitoring events can be detected within an Intel Xeon processor MP on a per logical processor basis (see Section 18.14.4, "Performance Monitoring Events"). Some sub-events (specified by an event mask bits) are counted or sampled without regard to which logical processor is associated with the detected event.

## 18.14.2 CCCR MSRs

Figure 18-42 shows the layout of a CCCR MSR in processors supporting Intel Hyper-Threading Technology. The functions of the flags and fields are as follows:

- **Enable flag, bit 12 —** When set, enables counting; when clear, the counter is disabled. This flag is cleared on reset
- **ESCR select field, bits 13 through 15 —** Identifies the ESCR to be used to select events to be counted with the counter associated with the CCCR.
- **Active thread field, bits 16 and 17 —** Enables counting depending on which logical processors are active (executing a thread). This field enables filtering of events based on the state (active or inactive) of the logical processors. The encodings of this field are as follows:

**00** — None. Count only when neither logical processor is active.

**01** — Single. Count only when one logical processor is active (either 0 or 1).

**10** — Both. Count only when both logical processors are active.

**11** — Any. Count when either logical processor is active.

A halted logical processor or a logical processor in the "wait for SIPI" state is considered inactive.

- **Compare flag, bit 18 —** When set, enables filtering of the event count; when clear, disables filtering. The filtering method is selected with the threshold, complement, and edge flags.

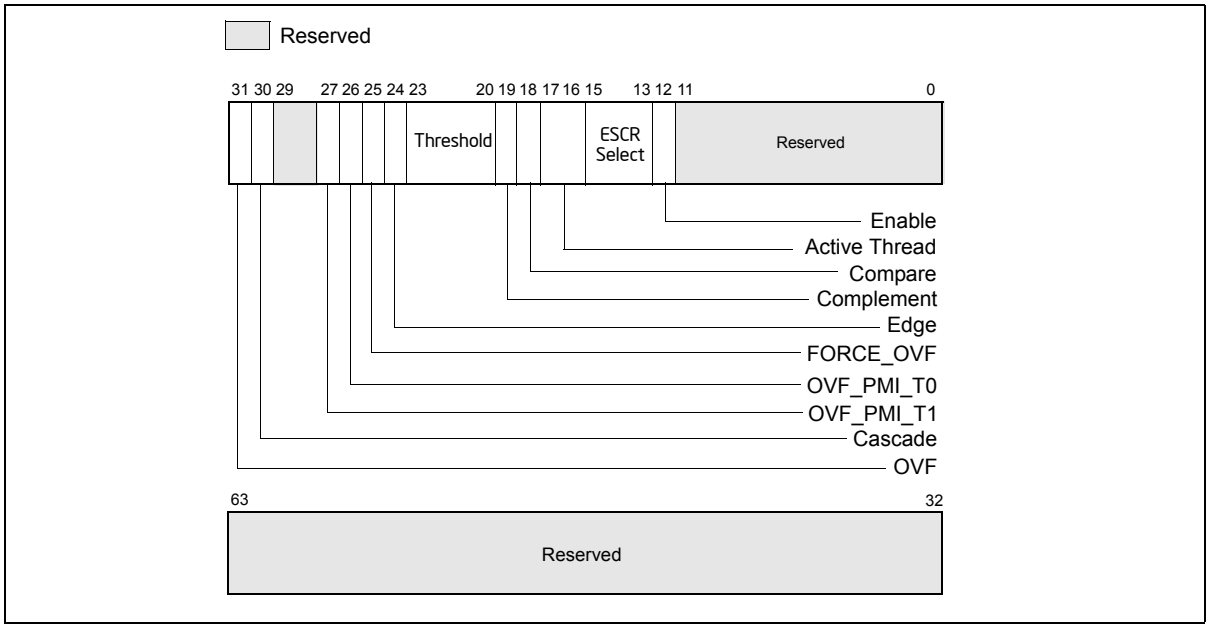

Figure 18-42. Counter Configuration Control Register (CCCR)

- **Complement flag, bit 19 —** Selects how the incoming event count is compared with the threshold value. When set, event counts that are less than or equal to the threshold value result in a single count being delivered to the performance counter; when clear, counts greater than the threshold value result in a count being delivered to the performance counter (see Section 18.13.5.2, "Filtering Events"). The compare flag is not active unless the compare flag is set.
- **Threshold field, bits 20 through 23 —** Selects the threshold value to be used for comparisons. The processor examines this field only when the compare flag is set, and uses the complement flag setting to determine the type of threshold comparison to be made. The useful range of values that can be entered in this field depend on the type of event being counted (see Section 18.13.5.2, "Filtering Events").
- **Edge flag, bit 24 —** When set, enables rising edge (false-to-true) edge detection of the threshold comparison output for filtering event counts; when clear, rising edge detection is disabled. This flag is active only when the compare flag is set.
- **FORCE_OVF flag, bit 25 —** When set, forces a counter overflow on every counter increment; when clear, overflow only occurs when the counter actually overflows.
- **OVF_PMI_T0 flag, bit 26 —** When set, causes a performance monitor interrupt (PMI) to be sent to logical processor 0 when the counter overflows occurs; when clear, disables PMI generation for logical processor 0. Note that the PMI is generate on the next event count after the counter has overflowed.
- **OVF_PMI_T1 flag, bit 27 —** When set, causes a performance monitor interrupt (PMI) to be sent to logical processor 1 when the counter overflows occurs; when clear, disables PMI generation for logical processor 1. Note that the PMI is generate on the next event count after the counter has overflowed.

- **Cascade flag, bit 30 —** When set, enables counting on one counter of a counter pair when its alternate counter in the other the counter pair in the same counter group overflows (see Section 18.13.2, "Performance Counters," for further details); when clear, disables cascading of counters.
- **OVF flag, bit 31 —** Indicates that the counter has overflowed when set. This flag is a sticky flag that must be explicitly cleared by software.

### 18.14.3 IA32_PEBS_ENABLE MSR

In a processor supporting Intel Hyper-Threading Technology and based on the Intel NetBurst microarchitecture, PEBS is enabled and qualified with two bits in the MSR_PEBS_ENABLE MSR: bit 25 (ENABLE_PEBS_MY_THR) and 26 (ENABLE_PEBS_OTH_THR) respectively. These bits do not explicitly identify a specific logical processor by logic processor ID(T0 or T1); instead, they allow a software agent to enable PEBS for subsequent threads of execution on the same logical processor on which the agent is running ("my thread") or for the other logical processor in the physical package on which the agent is not running ("other thread").

PEBS is supported for only a subset of the at-retirement events: Execution_event, Front_end_event, and Replay_event. Also, PEBS can be carried out only with two performance counters: MSR_IQ_CCCR4 (MSR address 370H) for logical processor 0 and MSR_IQ_CCCR5 (MSR address 371H) for logical processor 1.

Performance monitoring tools should use a processor affinity mask to bind the kernel mode components that need to modify the ENABLE_PEBS_MY_THR and ENABLE_PEBS_OTH_THR bits in the MSR_PEBS_ENABLE MSR to a specific logical processor. This is to prevent these kernel mode components from migrating between different logical processors due to OS scheduling.

### 18.14.4 Performance Monitoring Events

All of the events listed in Table 19-23 and 19-24 are available in an Intel Xeon processor MP. When Intel Hyper-Threading Technology is active, many performance monitoring events can be can be qualified by the logical processor ID, which corresponds to bit 0 of the initial APIC ID. This allows for counting an event in any or all of the logical processors. However, not all the events have this logic processor specificity, or thread specificity.

Here, each event falls into one of two categories:

- **Thread specific (TS) —** The event can be qualified as occurring on a specific logical processor.
- **Thread independent (TI) —** The event cannot be qualified as being associated with a specific logical processor.

Table 19-29 gives logical processor specific information (TS or TI) for each of the events described in Tables 19-23 and 19-24. If for example, a TS event occurred in logical processor T0, the counting of the event (as shown in Table 18-48) depends only on the setting of the T0_USR and T0_OS flags in the ESCR being used to set up the event counter. The T1_USR and T1_OS flags have no effect on the count.

**Table 18-48. Effect of Logical Processor and CPL Qualification for Logical-Processor-Specific (TS) Events**

| | T1_OS/T1_USR = 00 | T1_OS/T1_USR = 01 | T1_OS/T1_USR = 11 | T1_OS/T1_USR = 10 |
|---|---|---|---|---|
| T0_OS/T0_USR = 00 | Zero count | Counts while T1 in USR | Counts while T1 in OS or USR | Counts while T1 in OS |
| T0_OS/T0_USR = 01 | Counts while T0 in USR | Counts while T0 in USR or T1 in USR | Counts while (a) T0 in USR or (b) T1 in OS or (c) T1 in USR | Counts while (a) T0 in OS or (b) T1 in OS |
| T0_OS/T0_USR = 11 | Counts while T0 in OS or USR | Counts while (a) T0 in OS or (b) T0 in USR or (c) T1 in USR | Counts irrespective of CPL, T0, T1 | Counts while (a) T0 in OS or (b) or T0 in USR or (c) T1 in OS |
| T0_OS/T0_USR = 10 | Counts T0 in OS | Counts T0 in OS or T1 in USR | Counts while (a)T0 in Os or (b) T1 in OS or (c) T1 in USR | Counts while (a) T0 in OS or (b) T1 in OS |

When a bit in the event mask field is TI, the effect of specifying bit-0-3 of the associated ESCR are described in Table 15-6. For events that are marked as TI in Chapter 19, the effect of selectively specifying T0_USR, T0_OS, T1_USR, T1_OS bits is shown in Table 18-49.

**Table 18-49. Effect of Logical Processor and CPL Qualification for Non-logical-Processor-specific (TI) Events**

| | T1_OS/T1_USR = 00 | T1_OS/T1_USR = 01 | T1_OS/T1_USR = 11 | T1_OS/T1_USR = 10 |
|---|---|---|---|---|
| T0_OS/T0_USR = 00 | Zero count | Counts while (a) T0 in USR or (b) T1 in USR | Counts irrespective of CPL, T0, T1 | Counts while (a) T0 in OS or (b) T1 in OS |
| T0_OS/T0_USR = 01 | Counts while (a) T0 in USR or (b) T1 in USR | Counts while (a) T0 in USR or (b) T1 in USR | Counts irrespective of CPL, T0, T1 | Counts irrespective of CPL, T0, T1 |
| T0_OS/T0_USR = 11 | Counts irrespective of CPL, T0, T1 | Counts irrespective of CPL, T0, T1 | Counts irrespective of CPL, T0, T1 | Counts irrespective of CPL, T0, T1 |
| T0_OS/T0_USR = 0 | Counts while (a) T0 in OS or (b) T1 in OS | Counts irrespective of CPL, T0, T1 | Counts irrespective of CPL, T0, T1 | Counts while (a) T0 in OS or (b) T1 in OS |

## 18.15 COUNTING CLOCKS

The count of cycles, also known as clockticks, forms a the basis for measuring how long a program takes to execute. Clockticks are also used as part of efficiency ratios like cycles per instruction (CPI). Processor clocks may stop ticking under circumstances like the following:

- The processor is halted when there is nothing for the CPU to do. For example, the processor may halt to save power while the computer is servicing an I/O request. When Intel Hyper-Threading Technology is enabled, both logical processors must be halted for performance-monitoring counters to be powered down.
- The processor is asleep as a result of being halted or because of a power-management scheme. There are different levels of sleep. In the some deep sleep levels, the time-stamp counter stops counting.

In addition, processor core clocks may undergo transitions at different ratios relative to the processor's bus clock frequency. Some of the situations that can cause processor core clock to undergo frequency transitions include:

- TM2 transitions
- Enhanced Intel SpeedStep Technology transitions (P-state transitions)

For Intel processors that support Intel Dynamic Acceleration or XE operation, the processor core clocks may operate at a frequency that differs from the Processor Base frequency (as indicated by processor frequency information reported by CPUID instruction). See Section 18.15.5 for more detail.

There are several ways to count processor clock cycles to monitor performance. These are:

- **Non-halted clockticks —** Measures clock cycles in which the specified logical processor is not halted and is not in any power-saving state. When Intel Hyper-Threading Technology is enabled, ticks can be measured on a per-logical-processor basis. There are also performance events on dual-core processors that measure clockticks per logical processor when the processor is not halted.
- **Non-sleep clockticks —** Measures clock cycles in which the specified physical processor is not in a sleep mode or in a power-saving state. These ticks can**n**ot be measured on a logical-processor basis.
- **Time-stamp counter —** Measures clock cycles in which the physical processor is not in deep sleep. These ticks cannot be measured on a logical-processor basis.
- **Reference clockticks —** TM2 or Enhanced Intel SpeedStep technology are two examples of processor features that can cause processor core clockticks to represent non-uniform tick intervals due to change of bus ratios. Performance events that counts clockticks of a constant reference frequency was introduced Intel Core Duo and Intel Core Solo processors. The mechanism is further enhanced on processors based on Intel Core microarchitecture.

Some processor models permit clock cycles to be measured when the physical processor is not in deep sleep (by using the time-stamp counter and the RDTSC instruction). Note that such ticks cannot be measured on a per-logical-processor basis. See Section 17.13, "Time-Stamp Counter," for detail on processor capabilities.

The first two methods use performance counters and can be set up to cause an interrupt upon overflow (for sampling). They may also be useful where it is easier for a tool to read a performance counter than to use a time stamp counter (the timestamp counter is accessed using the RDTSC instruction).

For applications with a significant amount of I/O, there are two ratios of interest:

- **Non-halted CPI —** Non-halted clockticks/instructions retired measures the CPI for phases where the CPU was being used. This ratio can be measured on a logical-processor basis when Intel Hyper-Threading Technology is enabled.
- **Nominal CPI —** Time-stamp counter ticks/instructions retired measures the CPI over the duration of a program, including those periods when the machine halts while waiting for I/O.

### 18.15.1 Non-Halted Clockticks

Use the following procedure to program ESCRs and CCCRs to obtain non-halted clockticks on processors based on Intel NetBurst microarchitecture:

1. Select an ESCR for the global_power_events and specify the RUNNING sub-event mask and the desired T0_OS/T0_USR/T1_OS/T1_USR bits for the targeted processor.
2. Select an appropriate counter.
3. Enable counting in the CCCR for that counter by setting the enable bit.

### 18.15.2 Non-Sleep Clockticks

Performance monitoring counters can be configured to count clockticks whenever the performance monitoring hardware is not powered-down. To count Non-sleep Clockticks with a performance-monitoring counter, do the following:

1. Select one of the 18 counters.
2. Select any of the ESCRs whose events the selected counter can count. Set its event select to anything other than no_event. This may not seem necessary, but the counter may be disabled if this is not done.
3. Turn threshold comparison on in the CCCR by setting the compare bit to 1.
4. Set the threshold to 15 and the complement to 1 in the CCCR. Since no event can exceed this threshold, the threshold condition is met every cycle and the counter counts every cycle. Note that this overrides any qualification (e.g. by CPL) specified in the ESCR.
5. Enable counting in the CCCR for the counter by setting the enable bit.

In most cases, the counts produced by the non-halted and non-sleep metrics are equivalent if the physical package supports one logical processor and is not placed in a power-saving state. Operating systems may execute an HLT instruction and place a physical processor in a power-saving state.

On processors that support Intel Hyper-Threading Technology (Intel HT Technology), each physical package can support two or more logical processors. Current implementation of Intel HT Technology provides two logical processors for each physical processor. While both logical processors can execute two threads simultaneously, one logical processor may halt to allow the other logical processor to execute without sharing execution resources between two logical processors.

Non-halted Clockticks can be set up to count the number of processor clock cycles for each logical processor whenever the logical processor is not halted (the count may include some portion of the clock cycles for that logical processor to complete a transition to a halted state). Physical processors that support Intel HT Technology enter into a power-saving state if all logical processors halt.

The Non-sleep Clockticks mechanism uses a filtering mechanism in CCCRs. The mechanism will continue to increment as long as one logical processor is not halted or in a power-saving state. Applications may cause a processor to enter into a power-saving state by using an OS service that transfers control to an OS's idle loop. The idle loop then may place the processor into a power-saving state after an implementation-dependent period if there is no work for the processor.

### 18.15.3 Incrementing the Time-Stamp Counter

The time-stamp counter increments when the clock signal on the system bus is active and when the sleep pin is not asserted. The counter value can be read with the RDTSC instruction.

The time-stamp counter and the non-sleep clockticks count may not agree in all cases and for all processors. See Section 17.13, "Time-Stamp Counter," for more information on counter operation.

### 18.15.4 Non-Halted Reference Clockticks

Software can use either processor-specific performance monitor events (for example: CPU_CLK_UNHALTED.BUS on processors based on the Intel Core microarchitecture, and equivalent event specifications on the Intel Core Duo and Intel Core Solo processors) to count non-halted reference clockticks.

These events count reference clock cycles whenever the specified processor is not halted. The counter counts reference cycles associated with a fixed-frequency clock source irrespective of P-state, TM2, or frequency transitions that may occur to the processor.

### 18.15.5 Cycle Counting and Opportunistic Processor Operation

As a result of the state transitions due to opportunistic processor performance operation (see Chapter 14, "Power and Thermal Management"), a logical processor or a processor core can operate at frequency different from the Processor Base frequency.

The following items are expected to hold true irrespective of when opportunistic processor operation causes state transitions:

- The time stamp counter operates at a fixed-rate frequency of the processor.
- The IA32_MPERF counter increments at the same TSC frequency irrespective of any transitions caused by opportunistic processor operation.
- The IA32_FIXED_CTR2 counter increments at the same TSC frequency irrespective of any transitions caused by opportunistic processor operation.
- The Local APIC timer operation is unaffected by opportunistic processor operation.
- The TSC, IA32_MPERF, and IA32_FIXED_CTR2 operate at the same, maximum-resolved frequency of the platform, which is equal to the product of scalable bus frequency and maximum resolved bus ratio.

For processors based on Intel Core microarchitecture, the scalable bus frequency is encoded in the bit field MSR_FSB_FREQ[2:0] at (0CDH), see Chapter 35, "Model-Specific Registers (MSRs)". The maximum resolved bus ratio can be read from the following bit field:

- If XE operation is disabled, the maximum resolved bus ratio can be read in MSR_PLATFORM_ID[12:8]. It corresponds to the Processor Base frequency.
- IF XE operation is enabled, the maximum resolved bus ratio is given in MSR_PERF_STAT[44:40], it corresponds to the maximum XE operation frequency configured by BIOS.

XE operation of an Intel 64 processor is implementation specific. XE operation can be enabled only by BIOS. If MSR_PERF_STAT[31] is set, XE operation is enabled. The MSR_PERF_STAT[31] field is read-only.

## 18.16 PERFORMANCE MONITORING, BRANCH PROFILING AND SYSTEM EVENTS

When performance monitoring facilities and/or branch profiling facilities (see Section 17.5, "Last Branch, Interrupt, and Exception Recording (Intel® Core™ 2 Duo and Intel® Atom™ Processor Family)") are enabled, these facilities capture event counts, branch records and branch trace messages occurring in a logical processor. The occurrence of interrupts, instruction streams due to various interrupt handlers all contribute to the results recorded by these facilities.

If CPUID.01H:ECX.PDCM[bit 15] is 1, the processor supports the IA32_PERF_CAPABILITIES MSR. If IA32_PERF_CAPABILITIES.FREEZE_WHILE_SMM[Bit 12] is 1, the processor supports the ability for system soft-

ware using performance monitoring and/or branch profiling facilities to filter out the effects of servicing system management interrupts.

If the FREEZE_WHILE_SMM capability is enabled on a logical processor and after an SMI is delivered, the processor will clear all the enable bits of IA32_PERF_GLOBAL_CTRL, save a copy of the content of IA32_DEBUGCTL and disable LBR, BTF, TR, and BTS fields of IA32_DEBUGCTL before transferring control to the SMI handler.

The enable bits of IA32_PERF_GLOBAL_CTRL will be set to 1, the saved copy of IA32_DEBUGCTL prior to SMI delivery will be restored , after the SMI handler issues RSM to complete its servicing.

It is the responsibility of the SMM code to ensure the state of the performance monitoring and branch profiling facilities are preserved upon entry or until prior to exiting the SMM. If any of this state is modified due to actions by the SMM code, the SMM code is required to restore such state to the values present at entry to the SMM handler.

System software is allowed to set IA32_DEBUGCTL.FREEZE_WHILE_SMM_EN[bit 14] to 1 only supported as indicated by IA32_PERF_CAPABILITIES.FREEZE_WHILE_SMM[Bit 12] reporting 1.

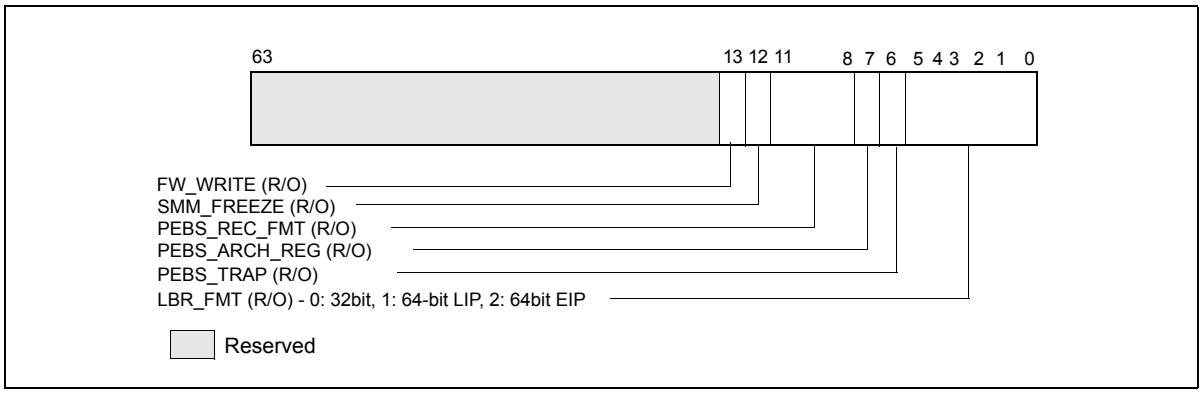

**Figure 18-43. Layout of IA32_PERF_CAPABILITIES MSR**

## 18.17 PERFORMANCE MONITORING AND DUAL-CORE TECHNOLOGY

The performance monitoring capability of dual-core processors duplicates the microarchitectural resources of a single-core processor implementation. Each processor core has dedicated performance monitoring resources.

In the case of Pentium D processor, each logical processor is associated with dedicated resources for performance monitoring. In the case of Pentium processor Extreme edition, each processor core has dedicated resources, but two logical processors in the same core share performance monitoring resources (see Section 18.14, "Performance Monitoring and Intel Hyper-Threading Technology in Processors Based on Intel NetBurst® Microarchitecture").

## 18.18 PERFORMANCE MONITORING ON 64-BIT INTEL XEON PROCESSOR MP WITH UP TO 8-MBYTE L3 CACHE

The 64-bit Intel Xeon processor MP with up to 8-MByte L3 cache has a CPUID signature of family [0FH], model [03H or 04H]. Performance monitoring capabilities available to Pentium 4 and Intel Xeon processors with the same values (see Section 18.1 and Section 18.14) apply to the 64-bit Intel Xeon processor MP with an L3 cache.

The level 3 cache is connected between the system bus and IOQ through additional control logic. See Figure 18-44.

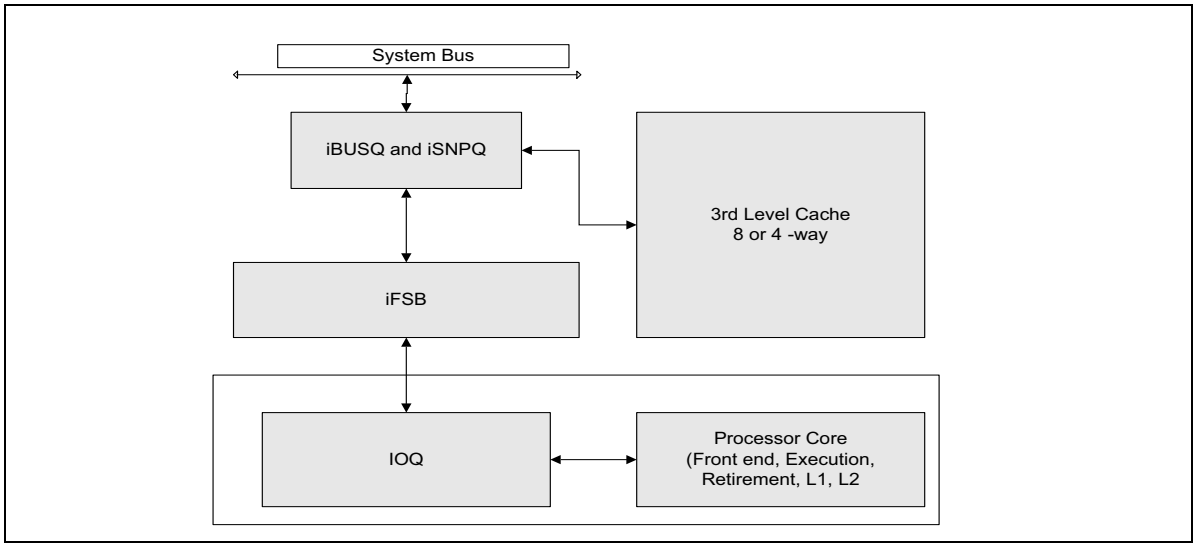

**Figure 18-44. Block Diagram of 64-bit Intel Xeon Processor MP with 8-MByte L3**

Additional performance monitoring capabilities and facilities unique to 64-bit Intel Xeon processor MP with an L3 cache are described in this section. The facility for monitoring events consists of a set of dedicated model-specific registers (MSRs), each dedicated to a specific event. Programming of these MSRs requires using RDMSR/WRMSR instructions with 64-bit values.

The lower 32-bits of the MSRs at addresses 107CC through 107D3 are treated as 32 bit performance counter registers. These performance counters can be accessed using RDPMC instruction with the index starting from 18 through 25. The EDX register returns zero when reading these 8 PMCs.

The performance monitoring capabilities consist of four events. These are:

- **IBUSQ event —** This event detects the occurrence of micro-architectural conditions related to the iBUSQ unit. It provides two MSRs: MSR_IFSB_IBUSQ0 and MSR_IFSB_IBUSQ1. Configure sub-event qualification and enable/disable functions using the high 32 bits of these MSRs. The low 32 bits act as a 32-bit event counter. Counting starts after software writes a non-zero value to one or more of the upper 32 bits. See Figure 18-45.

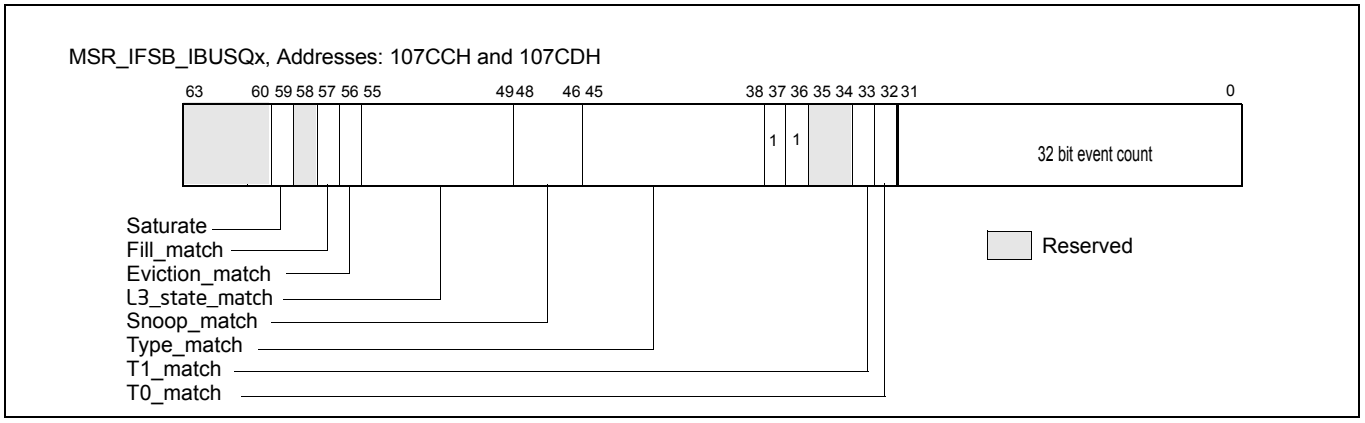

**Figure 18-45. MSR_IFSB_IBUSQx, Addresses: 107CCH and 107CDH**

- **ISNPQ event —** This event detects the occurrence of microarchitectural conditions related to the iSNPQ unit. It provides two MSRs: MSR_IFSB_ISNPQ0 and MSR_IFSB_ISNPQ1. Configure sub-event qualifications and enable/disable functions using the high 32 bits of the MSRs. The low 32-bits act as a 32-bit event counter. Counting starts after software writes a non-zero value to one or more of the upper 32-bits. See Figure 18-46.

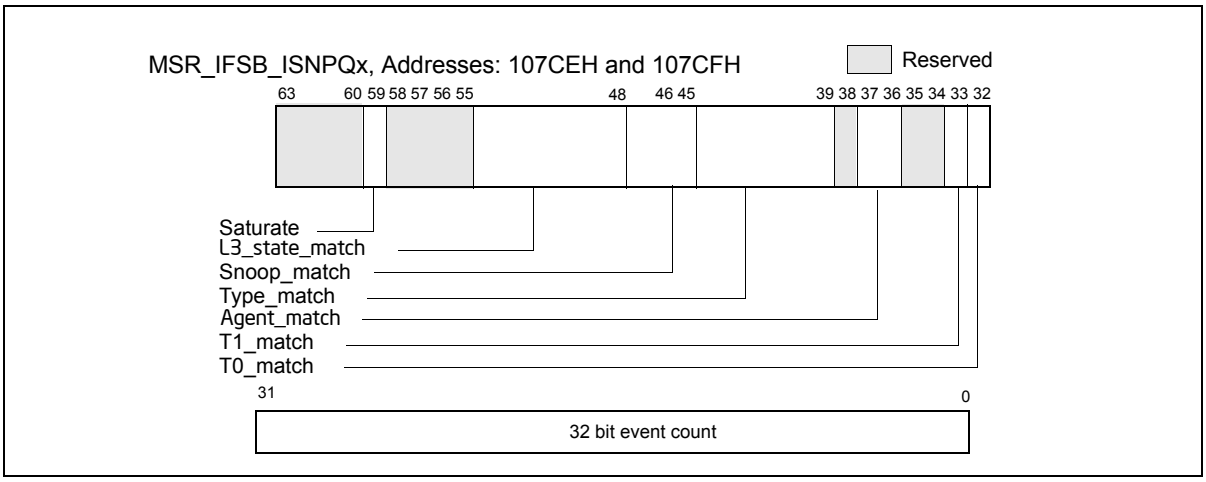

**Figure 18-46. MSR_IFSB_ISNPQx, Addresses: 107CEH and 107CFH**

- **EFSB event —** This event can detect the occurrence of micro-architectural conditions related to the iFSB unit or system bus. It provides two MSRs: MSR_EFSB_DRDY0 and MSR_EFSB_DRDY1. Configure sub-event qualifications and enable/disable functions using the high 32 bits of the 64-bit MSR. The low 32-bit act as a 32-bit event counter. Counting starts after software writes a non-zero value to one or more of the qualification bits in the upper 32-bits of the MSR. See Figure 18-47.

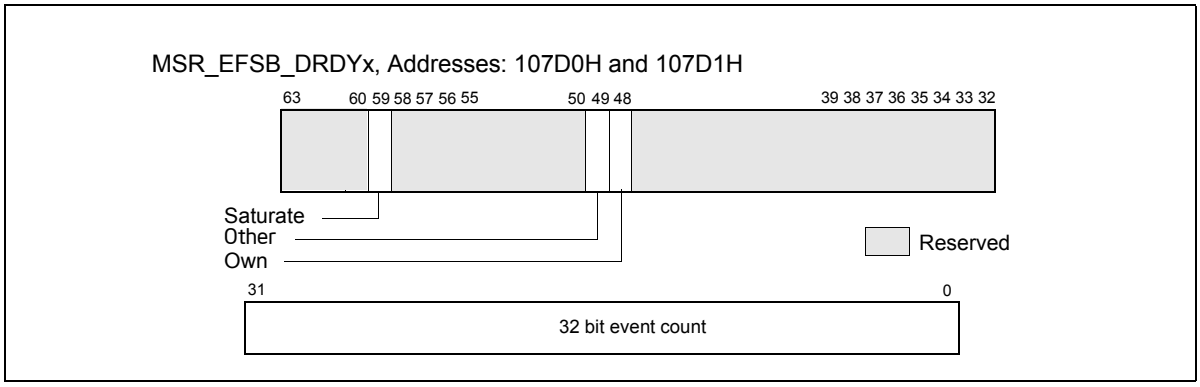

**Figure 18-47. MSR_EFSB_DRDYx, Addresses: 107D0H and 107D1H**

- **IBUSQ Latency event —** This event accumulates weighted cycle counts for latency measurement of transactions in the iBUSQ unit. The count is enabled by setting MSR_IFSB_CTRL6[bit 26] to 1; the count freezes after software sets MSR_IFSB_CTRL6[bit 26] to 0. MSR_IFSB_CNTR7 acts as a 64-bit event counter for this event. See Figure 18-48.

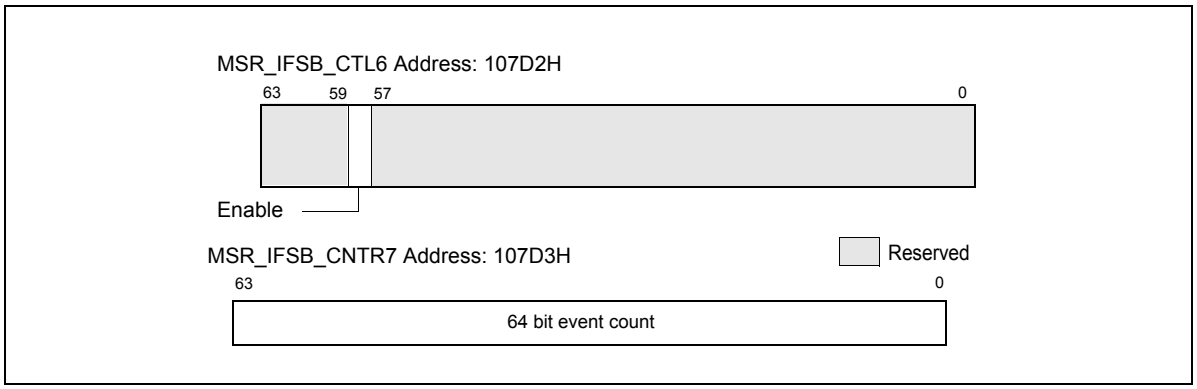

**Figure 18-48. MSR_IFSB_CTL6, Address: 107D2H; MSR_IFSB_CNTR7, Address: 107D3H**

## 18.19 PERFORMANCE MONITORING ON L3 AND CACHING BUS CONTROLLER SUB-SYSTEMS

The Intel Xeon processor 7400 series and Dual-Core Intel Xeon processor 7100 series employ a distinct L3/caching bus controller sub-system. These sub-system have a unique set of performance monitoring capability and programming interfaces that are largely common between these two processor families.

Intel Xeon processor 7400 series are based on 45nm enhanced Intel Core microarchitecture. The CPUID signature is indicated by DisplayFamily_DisplayModel value of 06_1DH (see CPUID instruction in Chapter 3, "Instruction Set Reference, A-M" in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*). Intel Xeon processor 7400 series have six processor cores that share an L3 cache.

Dual-Core Intel Xeon processor 7100 series are based on Intel NetBurst microarchitecture, have a CPUID signature of family [0FH], model [06H] and a unified L3 cache shared between two cores. Each core in an Intel Xeon processor 7100 series supports Intel Hyper-Threading Technology, providing two logical processors per core.

Both Intel Xeon processor 7400 series and Intel Xeon processor 7100 series support multi-processor configurations using system bus interfaces. In Intel Xeon processor 7400 series, the L3/caching bus controller sub-system provides three Simple Direct Interface (SDI) to service transactions originated the XQ-replacement SDI logic in each dual-core modules. In Intel Xeon processor 7100 series, the IOQ logic in each processor core is replaced with a Simple Direct Interface (SDI) logic. The L3 cache is connected between the system bus and the SDI through additional control logic. See Figure 18-49 for the block configuration of six processor cores and the L3/Caching bus controller sub-system in Intel Xeon processor 7400 series. Figure 18-49 shows the block configuration of two processor cores (four logical processors) and the L3/Caching bus controller sub-system in Intel Xeon processor 7100 series.

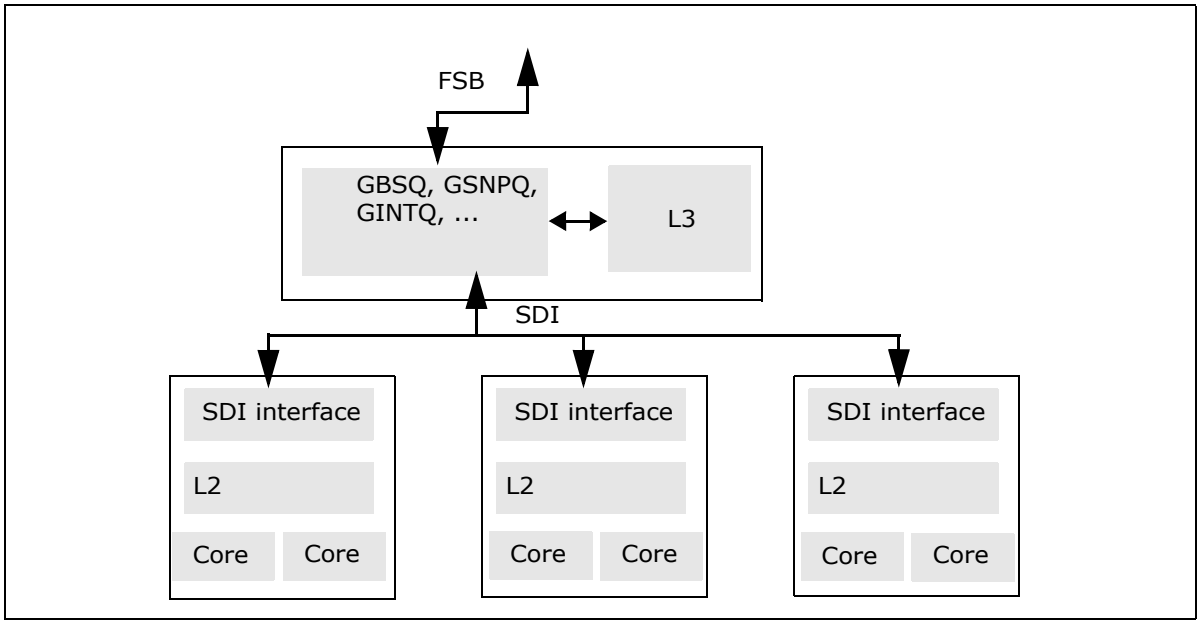

Figure 18-49. Block Diagram of Intel Xeon Processor 7400 Series

Almost all of the performance monitoring capabilities available to processor cores with the same CPUID signatures (see Section 18.1 and Section 18.14) apply to Intel Xeon processor 7100 series. The MSRs used by performance monitoring interface are shared between two logical processors in the same processor core.

The performance monitoring capabilities available to processor with DisplayFamily_DisplayModel signature 06_17H also apply to Intel Xeon processor 7400 series. Each processor core provides its own set of MSRs for performance monitoring interface.

The IOQ_allocation and IOQ_active_entries events are not supported in Intel Xeon processor 7100 series and 7400 series. Additional performance monitoring capabilities applicable to the L3/caching bus controller sub-system are described in this section.

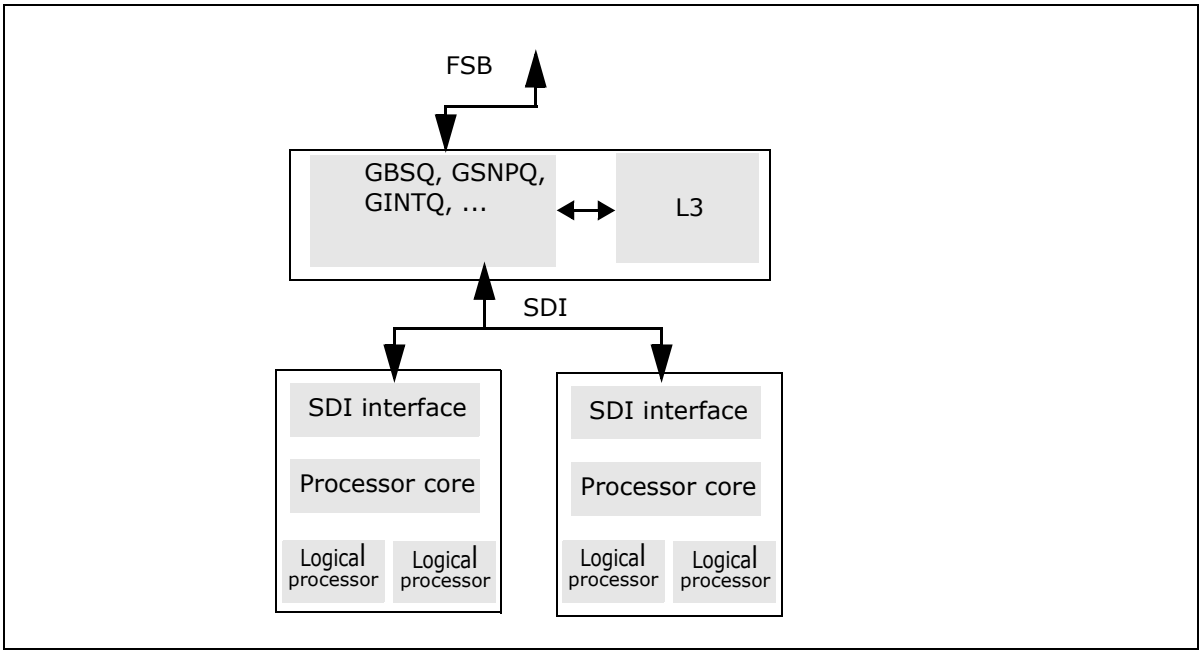

Figure 18-50. Block Diagram of Intel Xeon Processor 7100 Series

### 18.19.1 Overview of Performance Monitoring with L3/Caching Bus Controller

The facility for monitoring events consists of a set of dedicated model-specific registers (MSRs). There are eight event select/counting MSRs that are dedicated to counting events associated with specified microarchitectural conditions. Programming of these MSRs requires using RDMSR/WRMSR instructions with 64-bit values. In addition, an MSR MSR_EMON_L3_GL_CTL provides simplified interface to control freezing, resetting, re-enabling operation of any combination of these event select/counting MSRs.

The eight MSRs dedicated to count occurrences of specific conditions are further divided to count three sub-classes of microarchitectural conditions:

- Two MSRs (MSR_EMON_L3_CTR_CTL0 and MSR_EMON_L3_CTR_CTL1) are dedicated to counting GBSQ events. Up to two GBSQ events can be programmed and counted simultaneously.
- Two MSRs (MSR_EMON_L3_CTR_CTL2 and MSR_EMON_L3_CTR_CTL3) are dedicated to counting GSNPQ events. Up to two GBSQ events can be programmed and counted simultaneously.
- Four MSRs (MSR_EMON_L3_CTR_CTL4, MSR_EMON_L3_CTR_CTL5, MSR_EMON_L3_CTR_CTL6, and MSR_EMON_L3_CTR_CTL7) are dedicated to counting external bus operations.

The bit fields in each of eight MSRs share the following common characteristics:

- Bits 63:32 is the event control field that includes an event mask and other bit fields that control counter operation. The event mask field specifies details of the microarchitectural condition, and its definition differs across GBSQ, GSNPQ, FSB.
- Bits 31:0 is the event count field. If the specified condition is met during each relevant clock domain of the event logic, the matched condition signals the counter logic to increment the associated event count field. The lower 32-bits of these 8 MSRs at addresses 107CC through 107D3 are treated as 32 bit performance counter registers.

In Dual-Core Intel Xeon processor 7100 series, the uncore performance counters can be accessed using RDPMC instruction with the index starting from 18 through 25. The EDX register returns zero when reading these 8 PMCs.

In Intel Xeon processor 7400 series, RDPMC with ECX between 2 and 9 can be used to access the eight uncore performance counter/control registers.

### 18.19.2 GBSQ Event Interface

The layout of MSR_EMON_L3_CTR_CTL0 and MSR_EMON_L3_CTR_CTL1 is given in Figure 18-51. Counting starts after software writes a non-zero value to one or more of the upper 32 bits.

The event mask field (bits 58:32) consists of the following eight attributes:

- Agent_Select (bits 35:32): The definition of this field differs slightly between Intel Xeon processor 7100 and 7400.

  For Intel Xeon processor 7100 series, each bit specifies a logical processor in the physical package. The lower two bits corresponds to two logical processors in the first processor core, the upper two bits corresponds to two logical processors in the second processor core. 0FH encoding matches transactions from any logical processor.

  For Intel Xeon processor 7400 series, each bit of [34:32] specifies the SDI logic of a dual-core module as the originator of the transaction. A value of 0111B in bits [35:32] specifies transaction from any processor core.

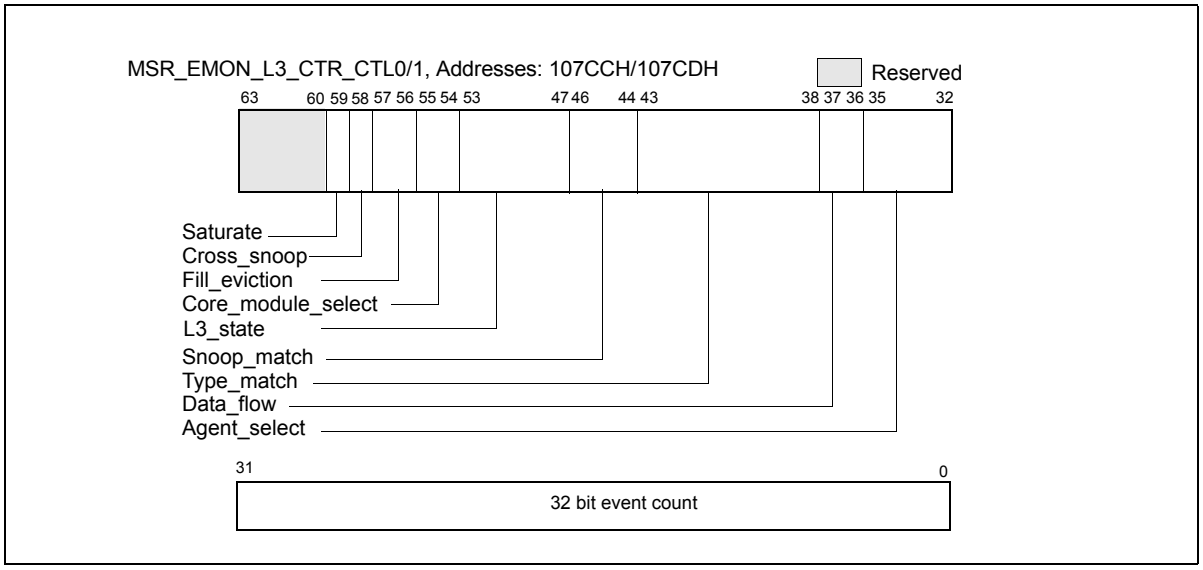

**Figure 18-51. MSR_EMON_L3_CTR_CTL0/1, Addresses: 107CCH/107CDH**

- Data_Flow (bits 37:36): Bit 36 specifies demand transactions, bit 37 specifies prefetch transactions.
- Type_Match (bits 43:38): Specifies transaction types. If all six bits are set, event count will include all transaction types.
- Snoop_Match: (bits 46:44): The three bits specify (in ascending bit position) clean snoop result, HIT snoop result, and HITM snoop results respectively.
- L3_State (bits 53:47): Each bit specifies an L2 coherency state.
- Core_Module_Select (bits 55:54): The valid encodings for L3 lookup differ slightly between Intel Xeon processor 7100 and 7400.

  For Intel Xeon processor 7100 series,

  — 00B: Match transactions from any core in the physical package

  — 01B: Match transactions from this core only

  — 10B: Match transactions from the other core in the physical package

  — 11B: Match transaction from both cores in the physical package

  For Intel Xeon processor 7400 series,

  — 00B: Match transactions from any dual-core module in the physical package

  — 01B: Match transactions from this dual-core module only

  — 10B: Match transactions from either one of the other two dual-core modules in the physical package

  — 11B: Match transaction from more than one dual-core modules in the physical package
- Fill_Eviction (bits 57:56): The valid encodings are

  — 00B: Match any transactions

  — 01B: Match transactions that fill L3

  — 10B: Match transactions that fill L3 without an eviction

  — 11B: Match transaction fill L3 with an eviction
- Cross_Snoop (bit 58): The encodings are \

  — 0B: Match any transactions

  — 1B: Match cross snoop transactions

For each counting clock domain, if all eight attributes match, event logic signals to increment the event count field.

### 18.19.3 GSNPQ Event Interface

The layout of MSR_EMON_L3_CTR_CTL2 and MSR_EMON_L3_CTR_CTL3 is given in Figure 18-52. Counting starts after software writes a non-zero value to one or more of the upper 32 bits.

The event mask field (bits 58:32) consists of the following six attributes:

- Agent_Select (bits 37:32): The definition of this field differs slightly between Intel Xeon processor 7100 and 7400.
- For Intel Xeon processor 7100 series, each of the lowest 4 bits specifies a logical processor in the physical package. The lowest two bits corresponds to two logical processors in the first processor core, the next two bits corresponds to two logical processors in the second processor core. Bit 36 specifies other symmetric agent transactions. Bit 37 specifies central agent transactions. 3FH encoding matches transactions from any logical processor.

  For Intel Xeon processor 7400 series, each of the lowest 3 bits specifies a dual-core module in the physical package. Bit 37 specifies central agent transactions.
- Type_Match (bits 43:38): Specifies transaction types. If all six bits are set, event count will include any transaction types.
- Snoop_Match: (bits 46:44): The three bits specify (in ascending bit position) clean snoop result, HIT snoop result, and HITM snoop results respectively.
- L2_State (bits 53:47): Each bit specifies an L3 coherency state.
- Core_Module_Select (bits 56:54): Bit 56 enables Core_Module_Select matching. If bit 56 is clear, Core_Module_Select encoding is ignored. The valid encodings for the lower two bits (bit 55, 54) differ slightly between Intel Xeon processor 7100 and 7400.

  For Intel Xeon processor 7100 series, if bit 56 is set, the valid encodings for the lower two bits (bit 55, 54) are
  - 00B: Match transactions from only one core (irrespective which core) in the physical package
  - 01B: Match transactions from this core and not the other core
  - 10B: Match transactions from the other core in the physical package, but not this core
  - 11B: Match transaction from both cores in the physical package

  For Intel Xeon processor 7400 series, if bit 56 is set, the valid encodings for the lower two bits (bit 55, 54) are
  - 00B: Match transactions from only one dual-core module (irrespective which module) in the physical package
  - 01B: Match transactions from one or more dual-core modules.
  - 10B: Match transactions from two or more dual-core modules.
  - 11B: Match transaction from all three dual-core modules in the physical package
- Block_Snoop (bit 57): specifies blocked snoop.

For each counting clock domain, if all six attributes match, event logic signals to increment the event count field.

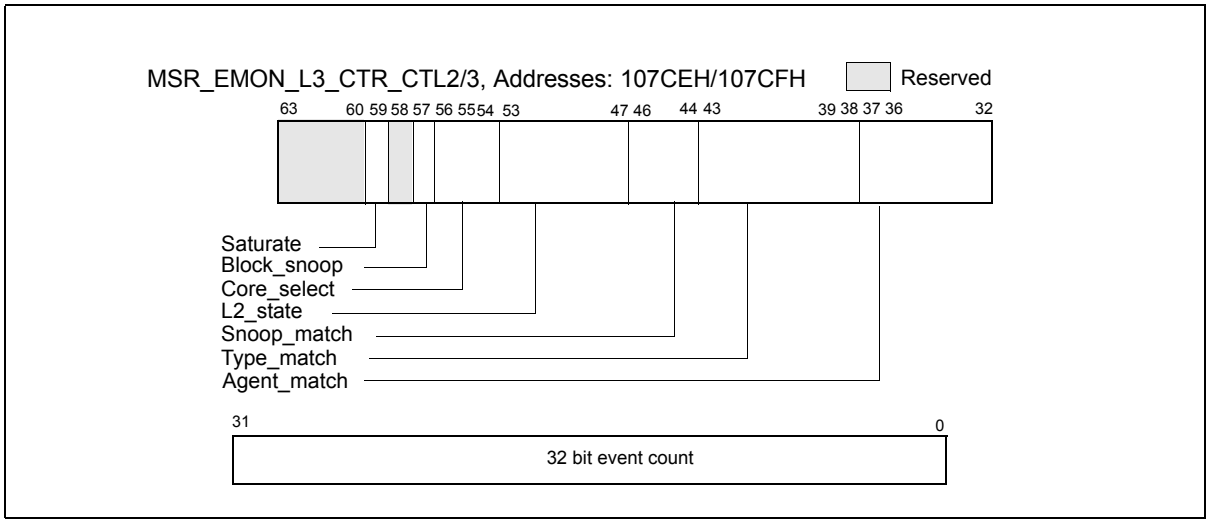

Figure 18-52. MSR_EMON_L3_CTR_CTL2/3, Addresses: 107CEH/107CFH

## 18.19.4 FSB Event Interface

The layout of MSR_EMON_L3_CTR_CTL4 through MSR_EMON_L3_CTR_CTL7 is given in Figure 18-53. Counting starts after software writes a non-zero value to one or more of the upper 32 bits.

The event mask field (bits 58:32) is organized as follows:

- Bit 58: must set to 1.
- FSB_Submask (bits 57:32): Specifies FSB-specific sub-event mask.

The FSB sub-event mask defines a set of independent attributes. The event logic signals to increment the associated event count field if one of the attribute matches. Some of the sub-event mask bit counts durations. A duration event increments at most once per cycle.

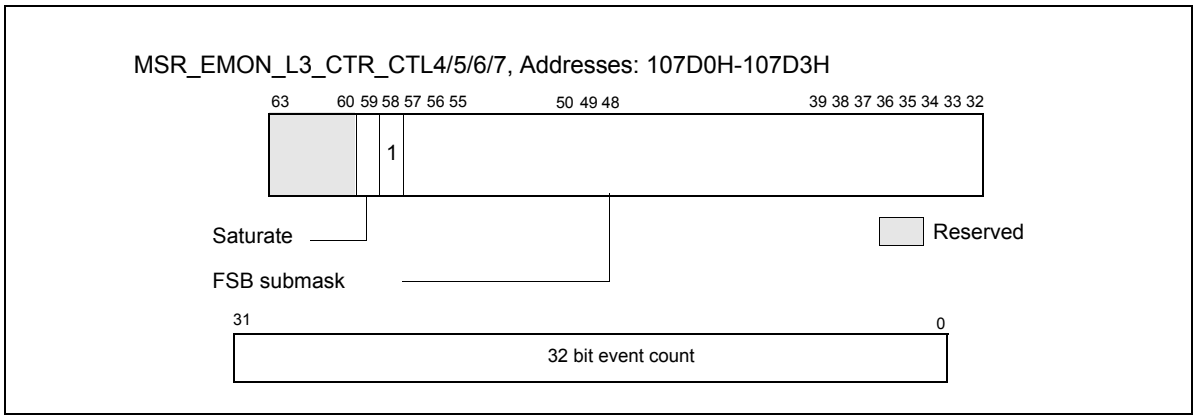

Figure 18-53. MSR_EMON_L3_CTR_CTL4/5/6/7, Addresses: 107D0H-107D3H

### 18.19.4.1 FSB Sub-Event Mask Interface

- FSB_type (bit 37:32): Specifies different FSB transaction types originated from this physical package
- FSB_L_clear (bit 38): Count clean snoop results from any source for transaction originated from this physical package
- FSB_L_hit (bit 39): Count HIT snoop results from any source for transaction originated from this physical package

- FSB_L_hitm (bit 40): Count HITM snoop results from any source for transaction originated from this physical package
- FSB_L_defer (bit 41): Count DEFER responses to this processor's transactions
- FSB_L_retry (bit 42): Count RETRY responses to this processor's transactions
- FSB_L_snoop_stall (bit 43): Count snoop stalls to this processor's transactions
- FSB_DBSY (bit 44): Count DBSY assertions by this processor (without a concurrent DRDY)
- FSB_DRDY (bit 45): Count DRDY assertions by this processor
- FSB_BNR (bit 46): Count BNR assertions by this processor
- FSB_IOQ_empty (bit 47): Counts each bus clocks when the IOQ is empty
- FSB_IOQ_full (bit 48): Counts each bus clocks when the IOQ is full
- FSB_IOQ_active (bit 49): Counts each bus clocks when there is at least one entry in the IOQ
- FSB_WW_data (bit 50): Counts back-to-back write transaction's data phase.
- FSB_WW_issue (bit 51): Counts back-to-back write transaction request pairs issued by this processor.
- FSB_WR_issue (bit 52): Counts back-to-back write-read transaction request pairs issued by this processor.
- FSB_RW_issue (bit 53): Counts back-to-back read-write transaction request pairs issued by this processor.
- FSB_other_DBSY (bit 54): Count DBSY assertions by another agent (without a concurrent DRDY)
- FSB_other_DRDY (bit 55): Count DRDY assertions by another agent
- FSB_other_snoop_stall (bit 56): Count snoop stalls on the FSB due to another agent
- FSB_other_BNR (bit 57): Count BNR assertions from another agent

### 18.19.5 Common Event Control Interface

The MSR_EMON_L3_GL_CTL MSR provides simplified access to query overflow status of the GBSQ, GSNPQ, FSB event counters. It also provides control bit fields to freeze, unfreeze, or reset those counters. The following bit fields are supported:

- GL_freeze_cmd (bit 0): Freeze the event counters specified by the GL_event_select field.
- GL_unfreeze_cmd (bit 1): Unfreeze the event counters specified by the GL_event_select field.
- GL_reset_cmd (bit 2): Clear the event count field of the event counters specified by the GL_event_select field. The event select field is not affected.
- GL_event_select (bit 23:16): Selects one or more event counters to subject to specified command operations indicated by bits 2:0. Bit 16 corresponds to MSR_EMON_L3_CTR_CTL0, bit 23 corresponds to MSR_EMON_L3_CTR_CTL7.
- GL_event_status (bit 55:48): Indicates the overflow status of each event counters. Bit 48 corresponds to MSR_EMON_L3_CTR_CTL0, bit 55 corresponds to MSR_EMON_L3_CTR_CTL7.

In the event control field (bits 63:32) of each MSR, if the saturate control (bit 59, see Figure 18-51 for example) is set, the event logic forces the value FFFF_FFFFH into the event count field instead of incrementing it.

## 18.20 PERFORMANCE MONITORING (P6 FAMILY PROCESSOR)

The P6 family processors provide two 40-bit performance counters, allowing two types of events to be monitored simultaneously. These can either count events or measure duration. When counting events, a counter increments each time a specified event takes place or a specified number of events takes place. When measuring duration, it counts the number of processor clocks that occur while a specified condition is true. The counters can count events or measure durations that occur at any privilege level.

Table 19-32, Chapter 19, lists the events that can be counted with the P6 family performance monitoring counters.

**NOTE**

The performance-monitoring events listed in Chapter 19 are intended to be used as guides for performance tuning. Counter values reported are not guaranteed to be accurate and should be used as a relative guide for tuning. Known discrepancies are documented where applicable.

The performance-monitoring counters are supported by four MSRs: the performance event select MSRs (PerfEvtSel0 and PerfEvtSel1) and the performance counter MSRs (PerfCtr0 and PerfCtr1). These registers can be read from and written to using the RDMSR and WRMSR instructions, respectively. They can be accessed using these instructions only when operating at privilege level 0. The PerfCtr0 and PerfCtr1 MSRs can be read from any privilege level using the RDPMC (read performance-monitoring counters) instruction.

**NOTE**

The PerfEvtSel0, PerfEvtSel1, PerfCtr0, and PerfCtr1 MSRs and the events listed in Table 19-32 are model-specific for P6 family processors. They are not guaranteed to be available in other IA-32 processors.

## 18.20.1 PerfEvtSel0 and PerfEvtSel1 MSRs

The PerfEvtSel0 and PerfEvtSel1 MSRs control the operation of the performance-monitoring counters, with one register used to set up each counter. They specify the events to be counted, how they should be counted, and the privilege levels at which counting should take place. Figure 18-54 shows the flags and fields in these MSRs.

The functions of the flags and fields in the PerfEvtSel0 and PerfEvtSel1 MSRs are as follows:

- **Event select field (bits 0 through 7) —** Selects the event logic unit to detect certain microarchitectural conditions (see Table 19-32, for a list of events and their 8-bit codes).
- **Unit mask (UMASK) field (bits 8 through 15) —** Further qualifies the event logic unit selected in the event select field to detect a specific microarchitectural condition. For example, for some cache events, the mask is used as a MESI-protocol qualifier of cache states (see Table 19-32).

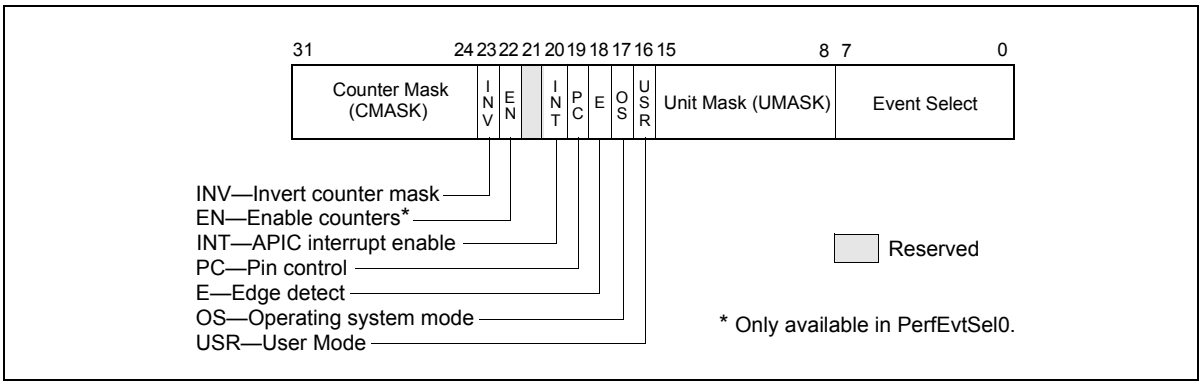

**Figure 18-54. PerfEvtSel0 and PerfEvtSel1 MSRs**

- **USR (user mode) flag (bit 16) —** Specifies that events are counted only when the processor is operating at privilege levels 1, 2 or 3. This flag can be used in conjunction with the OS flag.
- **OS (operating system mode) flag (bit 17) —** Specifies that events are counted only when the processor is operating at privilege level 0. This flag can be used in conjunction with the USR flag.
- **E (edge detect) flag (bit 18) —** Enables (when set) edge detection of events. The processor counts the number of deasserted to asserted transitions of any condition that can be expressed by the other fields. The mechanism is limited in that it does not permit back-to-back assertions to be distinguished. This mechanism allows software to measure not only the fraction of time spent in a particular state, but also the average length of time spent in such a state (for example, the time spent waiting for an interrupt to be serviced).

- **PC (pin control) flag (bit 19) —** When set, the processor toggles the PM*i* pins and increments the counter when performance-monitoring events occur; when clear, the processor toggles the PM*i* pins when the counter overflows. The toggling of a pin is defined as assertion of the pin for a single bus clock followed by deassertion.
- **INT (APIC interrupt enable) flag (bit 20) —** When set, the processor generates an exception through its local APIC on counter overflow.
- **EN (Enable Counters) Flag (bit 22) —** This flag is only present in the PerfEvtSel0 MSR. When set, performance counting is enabled in both performance-monitoring counters; when clear, both counters are disabled.
- **INV (invert) flag (bit 23) —** When set, inverts the counter-mask (CMASK) comparison, so that both greater than or equal to and less than comparisons can be made (0: greater than or equal; 1: less than). Note if counter-mask is programmed to zero, INV flag is ignored.
- **Counter mask (CMASK) field (bits 24 through 31) —** When nonzero, the processor compares this mask to the number of events counted during a single cycle. If the event count is greater than or equal to this mask, the counter is incremented by one. Otherwise the counter is not incremented. This mask can be used to count events only if multiple occurrences happen per clock (for example, two or more instructions retired per clock). If the counter-mask field is 0, then the counter is incremented each cycle by the number of events that occurred that cycle.

### 18.20.2 PerfCtr0 and PerfCtr1 MSRs

The performance-counter MSRs (PerfCtr0 and PerfCtr1) contain the event or duration counts for the selected events being counted. The RDPMC instruction can be used by programs or procedures running at any privilege level and in virtual-8086 mode to read these counters. The PCE flag in control register CR4 (bit 8) allows the use of this instruction to be restricted to only programs and procedures running at privilege level 0.

The RDPMC instruction is not serializing or ordered with other instructions. Thus, it does not necessarily wait until all previous instructions have been executed before reading the counter. Similarly, subsequent instructions may begin execution before the RDPMC instruction operation is performed.

Only the operating system, executing at privilege level 0, can directly manipulate the performance counters, using the RDMSR and WRMSR instructions. A secure operating system would clear the PCE flag during system initialization to disable direct user access to the performance-monitoring counters, but provide a user-accessible programming interface that emulates the RDPMC instruction.

The WRMSR instruction cannot arbitrarily write to the performance-monitoring counter MSRs (PerfCtr0 and PerfCtr1). Instead, the lower-order 32 bits of each MSR may be written with any value, and the high-order 8 bits are sign-extended according to the value of bit 31. This operation allows writing both positive and negative values to the performance counters.

### 18.20.3 Starting and Stopping the Performance-Monitoring Counters

The performance-monitoring counters are started by writing valid setup information in the PerfEvtSel0 and/or PerfEvtSel1 MSRs and setting the enable counters flag in the PerfEvtSel0 MSR. If the setup is valid, the counters begin counting following the execution of a WRMSR instruction that sets the enable counter flag. The counters can be stopped by clearing the enable counters flag or by clearing all the bits in the PerfEvtSel0 and PerfEvtSel1 MSRs. Counter 1 alone can be stopped by clearing the PerfEvtSel1 MSR.

### 18.20.4 Event and Time-Stamp Monitoring Software

To use the performance-monitoring counters and time-stamp counter, the operating system needs to provide an event-monitoring device driver. This driver should include procedures for handling the following operations:

- Feature checking
- Initialize and start counters
- Stop counters
- Read the event counters

- Read the time-stamp counter

The event monitor feature determination procedure must check whether the current processor supports the performance-monitoring counters and time-stamp counter. This procedure compares the family and model of the processor returned by the CPUID instruction with those of processors known to support performance monitoring. (The Pentium and P6 family processors support performance counters.) The procedure also checks the MSR and TSC flags returned to register EDX by the CPUID instruction to determine if the MSRs and the RDTSC instruction are supported.

The initialize and start counters procedure sets the PerfEvtSel0 and/or PerfEvtSel1 MSRs for the events to be counted and the method used to count them and initializes the counter MSRs (PerfCtr0 and PerfCtr1) to starting counts. The stop counters procedure stops the performance counters (see Section 18.20.3, "Starting and Stopping the Performance-Monitoring Counters").

The read counters procedure reads the values in the PerfCtr0 and PerfCtr1 MSRs, and a read time-stamp counter procedure reads the time-stamp counter. These procedures would be provided in lieu of enabling the RDTSC and RDPMC instructions that allow application code to read the counters.

### 18.20.5 Monitoring Counter Overflow

The P6 family processors provide the option of generating a local APIC interrupt when a performance-monitoring counter overflows. This mechanism is enabled by setting the interrupt enable flag in either the PerfEvtSel0 or the PerfEvtSel1 MSR. The primary use of this option is for statistical performance sampling.

To use this option, the operating system should do the following things on the processor for which performance events are required to be monitored:

- Provide an interrupt vector for handling the counter-overflow interrupt.
- Initialize the APIC PERF local vector entry to enable handling of performance-monitor counter overflow events.
- Provide an entry in the IDT that points to a stub exception handler that returns without executing any instructions.
- Provide an event monitor driver that provides the actual interrupt handler and modifies the reserved IDT entry to point to its interrupt routine.

When interrupted by a counter overflow, the interrupt handler needs to perform the following actions:

- Save the instruction pointer (EIP register), code-segment selector, TSS segment selector, counter values and other relevant information at the time of the interrupt.
- Reset the counter to its initial setting and return from the interrupt.

An event monitor application utility or another application program can read the information collected for analysis of the performance of the profiled application.

## 18.21 PERFORMANCE MONITORING (PENTIUM PROCESSORS)

The Pentium processor provides two 40-bit performance counters, which can be used to count events or measure duration. The counters are supported by three MSRs: the control and event select MSR (CESR) and the performance counter MSRs (CTR0 and CTR1). These can be read from and written to using the RDMSR and WRMSR instructions, respectively. They can be accessed using these instructions only when operating at privilege level 0.

Each counter has an associated external pin (PM0/BP0 and PM1/BP1), which can be used to indicate the state of the counter to external hardware.

#### NOTES

The CESR, CTR0, and CTR1 MSRs and the events listed in Table 19-33 are model-specific for the Pentium processor.

The performance-monitoring events listed in Chapter 19 are intended to be used as guides for performance tuning. Counter values reported are not guaranteed to be accurate and should be used as a relative guide for tuning. Known discrepancies are documented where applicable.

## 18.21.1 Control and Event Select Register (CESR)

The 32-bit control and event select MSR (CESR) controls the operation of performance-monitoring counters CTR0 and CTR1 and the associated pins (see Figure 18-55). To control each counter, the CESR register contains a 6-bit event select field (ES0 and ES1), a pin control flag (PC0 and PC1), and a 3-bit counter control field (CC0 and CC1). The functions of these fields are as follows:

- **ES0 and ES1 (event select) fields (bits 0-5, bits 16-21) —** Selects (by entering an event code in the field) up to two events to be monitored. See Table 19-33 for a list of available event codes.

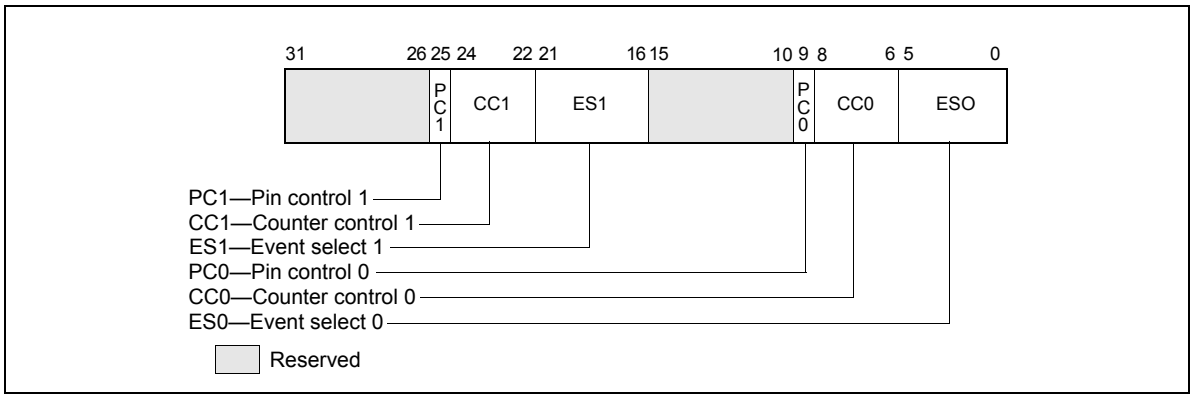

Figure 18-55. CESR MSR (Pentium Processor Only)

- **CC0 and CC1 (counter control) fields (bits 6-8, bits 22-24) —** Controls the operation of the counter. Control codes are as follows:

  000 — Count nothing (counter disabled)

  001 — Count the selected event while CPL is 0, 1, or 2

  010 — Count the selected event while CPL is 3

  011 — Count the selected event regardless of CPL

  100 — Count nothing (counter disabled)

  101 — Count clocks (duration) while CPL is 0, 1, or 2

  110 — Count clocks (duration) while CPL is 3

  111 — Count clocks (duration) regardless of CPL

  The highest order bit selects between counting events and counting clocks (duration); the middle bit enables counting when the CPL is 3; and the low-order bit enables counting when the CPL is 0, 1, or 2.

- **PC0 and PC1 (pin control) flags (bits 9, 25) —** Selects the function of the external performance-monitoring counter pin (PM0/BP0 and PM1/BP1). Setting one of these flags to 1 causes the processor to assert its associated pin when the counter has overflowed; setting the flag to 0 causes the pin to be asserted when the counter has been incremented. These flags permit the pins to be individually programmed to indicate the overflow or incremented condition. The external signalling of the event on the pins will lag the internal event by a few clocks as the signals are latched and buffered.

While a counter need not be stopped to sample its contents, it must be stopped and cleared or preset before switching to a new event. It is not possible to set one counter separately. If only one event needs to be changed, the CESR register must be read, the appropriate bits modified, and all bits must then be written back to CESR. At reset, all bits in the CESR register are cleared.

## 18.21.2 Use of the Performance-Monitoring Pins

When performance-monitor pins PM0/BP0 and/or PM1/BP1 are configured to indicate when the performance-monitor counter has incremented and an "occurrence event" is being counted, the associated pin is asserted (high) each time the event occurs. When a "duration event" is being counted, the associated PM pin is asserted for the

entire duration of the event. When the performance-monitor pins are configured to indicate when the counter has overflowed, the associated PM pin is asserted when the counter has overflowed.

When the PM0/BP0 and/or PM1/BP1 pins are configured to signal that a counter has incremented, it should be noted that although the counters may increment by 1 or 2 in a single clock, the pins can only indicate that the event occurred. Moreover, since the internal clock frequency may be higher than the external clock frequency, a single external clock may correspond to multiple internal clocks.

A "count up to" function may be provided when the event pin is programmed to signal an overflow of the counter. Because the counters are 40 bits, a carry out of bit 39 indicates an overflow. A counter may be preset to a specific value less then $2^{40} - 1$. After the counter has been enabled and the prescribed number of events has transpired, the counter will overflow.

Approximately 5 clocks later, the overflow is indicated externally and appropriate action, such as signaling an interrupt, may then be taken.

The PM0/BP0 and PM1/BP1 pins also serve to indicate breakpoint matches during in-circuit emulation, during which time the counter increment or overflow function of these pins is not available. After RESET, the PM0/BP0 and PM1/BP1 pins are configured for performance monitoring, however a hardware debugger may reconfigure these pins to indicate breakpoint matches.

### 18.21.3 Events Counted

Events that performance-monitoring counters can be set to count and record (using CTR0 and CTR1) are divided in two categories: occurrence and duration:

- **Occurrence events** — Counts are incremented each time an event takes place. If PM0/BP0 or PM1/BP1 pins are used to indicate when a counter increments, the pins are asserted each clock counters increment. But if an event happens twice in one clock, the counter increments by 2 (the pins are asserted only once).
- **Duration events** — Counters increment the total number of clocks that the condition is true. When used to indicate when counters increment, PM0/BP0 and/or PM1/BP1 pins are asserted for the duration.

# CHAPTER 19
# PERFORMANCE-MONITORING EVENTS

This chapter lists the performance-monitoring events that can be monitored with the Intel 64 or IA-32 processors. The ability to monitor performance events and the events that can be monitored in these processors are mostly model-specific, except for architectural performance events, described in Section 19.1.

Non-architectural performance events (i.e. model-specific events) are listed for each generation of microarchitecture:

- Section 19.2 - Processors based on Broadwell microarchitecture
- Section 19.3 - Processors based on Haswell microarchitecture
- Section 19.3.1 - Processors based on Haswell-E microarchitecture
- Section 19.4 - Processors based on Ivy Bridge microarchitecture
- Section 19.4.1 - Processors based on Ivy Bridge-E microarchitecture
- Section 19.5 - Processors based on Sandy Bridge microarchitecture
- Section 19.6 - Processors based on Intel® microarchitecture code name Nehalem
- Section 19.7 - Processors based on Intel® microarchitecture code name Westmere
- Section 19.8 - Processors based on Enhanced Intel® Core™ microarchitecture
- Section 19.9 - Processors based on Intel® Core™ microarchitecture
- Section 19.10 - Processors based on the Silvermont microarchitecture
- Section 19.11 - Processors based on Intel® Atom™ microarchitecture
- Section 19.12 - Intel® Core™ Solo and Intel® Core™ Duo processors
- Section 19.13 - Processors based on Intel NetBurst® microarchitecture
- Section 19.14 - Pentium® M family processors
- Section 19.15 - P6 family processors
- Section 19.16 - Pentium® processors

**NOTE**

These performance-monitoring events are intended to be used as guides for performance tuning. The counter values reported by the performance-monitoring events are approximate and believed to be useful as relative guides for tuning software. Known discrepancies are documented where applicable.

All performance event encodings not documented in the appropriate tables for the given processor are considered reserved, and their use will result in undefined counter updates with associated overflow actions.

The event tables list this chapter provide information for tool developers to support architectural and non-architectural performance monitoring events. Details of performance event implementation for end-user (including additional details beyond event code/umask) can found at the "perfmon" repository provided by The Intel Open Source Technology Center (https://download.01.org/perfmon/).

## 19.1 ARCHITECTURAL PERFORMANCE-MONITORING EVENTS

Architectural performance events are introduced in Intel Core Solo and Intel Core Duo processors. They are also supported on processors based on Intel Core microarchitecture. Table 19-1 lists pre-defined architectural performance events that can be configured using general-purpose performance counters and associated event-select registers.

Table 19-1. Architectural Performance Events

| Event Num. | Event Mask Mnemonic | Umask Value | Description | Comment |
|---|---|---|---|---|
| 3CH | UnHalted Core Cycles | 00H | Unhalted core cycles | |
| 3CH | UnHalted Reference Cycles | 01H | Unhalted reference cycles | Measures bus cycle[1] |
| C0H | Instruction Retired | 00H | Instruction retired | |
| 2EH | LLC Reference | 4FH | Longest latency cache references | |
| 2EH | LLC Misses | 41H | Longest latency cache misses | |
| C4H | Branch Instruction Retired | 00H | Branch instruction at retirement | |
| C5H | Branch Misses Retired | 00H | Mispredicted Branch Instruction at retirement | |

NOTES:

1. Implementation of this event in Intel Core 2 processor family, Intel Core Duo, and Intel Core Solo processors measures bus clocks.

## 19.2 PERFORMANCE MONITORING EVENTS FOR THE INTEL® CORE™ M PROCESSORS

The Intel® Core™ M processors are based on the Broadwell microarchitecture. They support the architectural performance-monitoring events listed in Table 19-1. Non-architectural performance-monitoring events in the processor core are listed in Table 19-3. The events in Table 19-3 apply to processors with CPUID signature of DisplayFamily_DisplayModel encoding with the following values: 06_3DH. Table 19-4 lists performance events supporting Intel TSX (see Section 18.11.5) and are available on processor based Broadwell microarchitecture.

Non-architectural performance monitoring events that are located in the uncore sub-system are implementation specific between different platforms using processors based on Haswell microarchitecture and with different DisplayFamily_DisplayModel signatures. Processors with CPUID signature of DisplayFamily_DisplayModel 06_3FH support performance events listed in Table 19-5.

Table 19-2. Non-Architectural Performance Events In the Processor Core of the Intel® Core™ M Processors

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 03H | 02H | LD_BLOCKS.STORE_FORWARD | loads blocked by overlapping with store buffer that cannot be forwarded . | |
| 03H | 08H | LD_BLOCKS.NO_SR | The number of times that split load operations are temporarily blocked because all resources for handling the split accesses are in use. | |
| 05H | 01H | MISALIGN_MEM_REF.LOADS | Speculative cache-line split load uops dispatched to L1D. | |
| 05H | 02H | MISALIGN_MEM_REF.STORES | Speculative cache-line split Store-address uops dispatched to L1D. | |
| 07H | 01H | LD_BLOCKS_PARTIAL.ADDRESS_ALIAS | False dependencies in MOB due to partial compare on address. | |
| 08H | 01H | DTLB_LOAD_MISSES.MISS_CAUSES_A_WALK | Misses in all TLB levels that cause a page walk of any page size. | |
| 08H | 02H | DTLB_LOAD_MISSES.WALK_COMPLETED_4K | Completed page walks due to demand load misses that caused 4K page walks in any TLB levels. | |
| 08H | 10H | DTLB_LOAD_MISSES.WALK_DURATION | Cycle PMH is busy with a walk. | |

Table 19-2. Non-Architectural Performance Events In the Processor Core of the Intel® Core™ M Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 08H | 20H | DTLB_LOAD_MISSES.STLB_HIT_4K | Load misses that missed DTLB but hit STLB (4K). | |
| 0DH | 03H | INT_MISC.RECOVERY_CYCLES | Cycles waiting to recover after Machine Clears except JEClear. Set Cmask= 1. | Set Edge to count occurrences |
| 0EH | 01H | UOPS_ISSUED.ANY | Increments each cycle the # of Uops issued by the RAT to RS.<br>Set Cmask = 1, Inv = 1, Any= 1to count stalled cycles of this core. | Set Cmask = 1, Inv = 1to count stalled cycles |
| 0EH | 10H | UOPS_ISSUED.FLAGS_MERGE | Number of flags-merge uops allocated. Such uops adds delay. | |
| 0EH | 20H | UOPS_ISSUED.SLOW_LEA | Number of slow LEA or similar uops allocated. Such uop has 3 sources (e.g. 2 sources + immediate) regardless if as a result of LEA instruction or not. | |
| 0EH | 40H | UOPS_ISSUED.SINGLE_MUL | Number of multiply packed/scalar single precision uops allocated. | |
| 14H | 01H | ARITH.FPU_DIV_ACTIVE | Cycles when divider is busy executing divide operations | |
| 24H | 21H | L2_RQSTS.DEMAND_DATA_RD_MISS | Demand Data Read requests that missed L2, no rejects. | |
| 24H | 41H | L2_RQSTS.DEMAND_DATA_RD_HIT | Demand Data Read requests that hit L2 cache. | |
| 24H | 50H | L2_RQSTS.L2_PF_HIT | Counts all L2 HW prefetcher requests that hit L2. | |
| 24H | 30H | L2_RQSTS.L2_PF_MISS | Counts all L2 HW prefetcher requests that missed L2. | |
| 24H | E1H | L2_RQSTS.ALL_DEMAND_DATA_RD | Counts any demand and L1 HW prefetch data load requests to L2. | |
| 24H | E2H | L2_RQSTS.ALL_RFO | Counts all L2 store RFO requests. | |
| 24H | E4H | L2_RQSTS.ALL_CODE_RD | Counts all L2 code requests. | |
| 24H | F8H | L2_RQSTS.ALL_PF | Counts all L2 HW prefetcher requests. | |
| 27H | 50H | L2_DEMAND_RQSTS.WB_HIT | Not rejected writebacks that hit L2 cache | |
| 2EH | 4FH | LONGEST_LAT_CACHE.REFERENCE | This event counts requests originating from the core that reference a cache line in the last level cache. | see Table 19-1 |
| 2EH | 41H | LONGEST_LAT_CACHE.MISS | This event counts each cache miss condition for references to the last level cache. | see Table 19-1 |
| 3CH | 00H | CPU_CLK_UNHALTED.THREAD_P | Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling. | see Table 19-1 |
| 3CH | 01H | CPU_CLK_THREAD_UNHALTED.REF_XCLK | Increments at the frequency of XCLK (100 MHz) when not halted. | see Table 19-1 |
| 48H | 01H | L1D_PEND_MISS.PENDING | Increments the number of outstanding L1D misses every cycle. Set Cmaks = 1 and Edge =1 to count occurrences. | Counter 2 only;<br>Set Cmask = 1 to count cycles. |
| 49H | 01H | DTLB_STORE_MISSES.MISS_CAUSES_A_WALK | Miss in all TLB levels causes an page walk of any page size (4K/2M/4M/1G). | |

**Table 19-2. Non-Architectural Performance Events In the Processor Core of the Intel® Core™ M Processors (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 49H | 02H | DTLB_STORE_MISSES.WALK_COMPLETED_4K | Completed page walks due to store misses in one or more TLB levels of 4K page structure. | |
| 49H | 10H | DTLB_STORE_MISSES.WALK_DURATION | Cycles PMH is busy with this walk. | |
| 49H | 20H | DTLB_STORE_MISSES.STLB_HIT_4K | Store misses that missed DTLB but hit STLB (4K). | |
| 4CH | 02H | LOAD_HIT_PRE.HW_PF | Non-SW-prefetch load dispatches that hit fill buffer allocated for H/W prefetch. | |
| 4FH | 10H | EPT.WALK_CYCLES | Cycles of Extended Page Table walks | |
| 51H | 01H | L1D.REPLACEMENT | Counts the number of lines brought into the L1 data cache. | |
| 58H | 04H | MOVE_ELIMINATION.INT_NOT_ELIMINATED | Number of integer Move Elimination candidate uops that were not eliminated. | |
| 58H | 08H | MOVE_ELIMINATION.SIMD_NOT_ELIMINATED | Number of SIMD Move Elimination candidate uops that were not eliminated. | |
| 58H | 01H | MOVE_ELIMINATION.INT_ELIMINATED | Number of integer Move Elimination candidate uops that were eliminated. | |
| 58H | 02H | MOVE_ELIMINATION.SIMD_ELIMINATED | Number of SIMD Move Elimination candidate uops that were eliminated. | |
| 5CH | 01H | CPL_CYCLES.RING0 | Unhalted core cycles when the thread is in ring 0. | Use Edge to count transition |
| 5CH | 02H | CPL_CYCLES.RING123 | Unhalted core cycles when the thread is not in ring 0. | |
| 5EH | 01H | RS_EVENTS.EMPTY_CYCLES | Cycles the RS is empty for the thread. | |
| 60H | 01H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_DATA_RD | Offcore outstanding Demand Data Read transactions in SQ to uncore. Set Cmask=1 to count cycles. | Use only when HTT is off |
| 60H | 02H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_CODE_RD | Offcore outstanding Demand code Read transactions in SQ to uncore. Set Cmask=1 to count cycles. | Use only when HTT is off |
| 60H | 04H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_RFO | Offcore outstanding RFO store transactions in SQ to uncore. Set Cmask=1 to count cycles. | Use only when HTT is off |
| 60H | 08H | OFFCORE_REQUESTS_OUTSTANDING.ALL_DATA_RD | Offcore outstanding cacheable data read transactions in SQ to uncore. Set Cmask=1 to count cycles. | Use only when HTT is off |
| 63H | 01H | LOCK_CYCLES.SPLIT_LOCK_UC_LOCK_DURATION | Cycles in which the L1D and L2 are locked, due to a UC lock or split lock. | |
| 63H | 02H | LOCK_CYCLES.CACHE_LOCK_DURATION | Cycles in which the L1D is locked. | |
| 79H | 02H | IDQ.EMPTY | Counts cycles the IDQ is empty. | |
| 79H | 04H | IDQ.MITE_UOPS | Increment each cycle # of uops delivered to IDQ from MITE path.<br>Set Cmask = 1 to count cycles. | Can combine Umask 04H and 20H |
| 79H | 08H | IDQ.DSB_UOPS | Increment each cycle. # of uops delivered to IDQ from DSB path.<br>Set Cmask = 1 to count cycles. | Can combine Umask 08H and 10H |
| 79H | 10H | IDQ.MS_DSB_UOPS | Increment each cycle # of uops delivered to IDQ when MS_busy by DSB. Set Cmask = 1 to count cycles. Add Edge=1 to count # of delivery. | Can combine Umask 04H, 08H |

Table 19-2. Non-Architectural Performance Events In the Processor Core of the Intel® Core™ M Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 79H | 20H | IDQ.MS_MITE_UOPS | Increment each cycle # of uops delivered to IDQ when MS_busy by MITE. Set Cmask = 1 to count cycles. | Can combine Umask 04H, 08H |
| 79H | 30H | IDQ.MS_UOPS | Increment each cycle # of uops delivered to IDQ from MS by either DSB or MITE. Set Cmask = 1 to count cycles. | Can combine Umask 04H, 08H |
| 79H | 18H | IDQ.ALL_DSB_CYCLES_ANY_UOPS | Counts cycles DSB is delivered at least one uops. Set Cmask = 1. | |
| 79H | 18H | IDQ.ALL_DSB_CYCLES_4_UOPS | Counts cycles DSB is delivered four uops. Set Cmask = 4. | |
| 79H | 24H | IDQ.ALL_MITE_CYCLES_ANY_UOPS | Counts cycles MITE is delivered at least one uops. Set Cmask = 1. | |
| 79H | 24H | IDQ.ALL_MITE_CYCLES_4_UOPS | Counts cycles MITE is delivered four uops. Set Cmask = 4. | |
| 79H | 3CH | IDQ.MITE_ALL_UOPS | # of uops delivered to IDQ from any path. | |
| 80H | 02H | ICACHE.MISSES | Number of Instruction Cache, Streaming Buffer and Victim Cache Misses. Includes UC accesses. | |
| 85H | 01H | ITLB_MISSES.MISS_CAUSES_A_WALK | Misses in ITLB that causes a page walk of any page size. | |
| 85H | 02H | ITLB_MISSES.WALK_COMPLETED_4K | Completed page walks due to misses in ITLB 4K page entries. | |
| 85H | 10H | ITLB_MISSES.WALK_DURATION | Cycle PMH is busy with a walk. | |
| 85H | 20H | ITLB_MISSES.STLB_HIT_4K | ITLB misses that hit STLB (4K). | |
| 87H | 01H | ILD_STALL.LCP | Stalls caused by changing prefix length of the instruction. | |
| 88H | 01H | BR_INST_EXEC.COND | Qualify conditional near branch instructions executed, but not necessarily retired. | Must combine with umask 40H, 80H |
| 88H | 02H | BR_INST_EXEC.DIRECT_JMP | Qualify all unconditional near branch instructions excluding calls and indirect branches. | Must combine with umask 80H |
| 88H | 04H | BR_INST_EXEC.INDIRECT_JMP_NON_CALL_RET | Qualify executed indirect near branch instructions that are not calls nor returns. | Must combine with umask 80H |
| 88H | 08H | BR_INST_EXEC.RETURN_NEAR | Qualify indirect near branches that have a return mnemonic. | Must combine with umask 80H |
| 88H | 10H | BR_INST_EXEC.DIRECT_NEAR_CALL | Qualify unconditional near call branch instructions, excluding non call branch, executed. | Must combine with umask 80H |
| 88H | 20H | BR_INST_EXEC.INDIRECT_NEAR_CALL | Qualify indirect near calls, including both register and memory indirect, executed. | Must combine with umask 80H |
| 88H | 40H | BR_INST_EXEC.NONTAKEN | Qualify non-taken near branches executed. | Applicable to umask 01H only |
| 88H | 80H | BR_INST_EXEC.TAKEN | Qualify taken near branches executed. Must combine with 01H,02H, 04H, 08H, 10H, 20H. | |
| 88H | FFH | BR_INST_EXEC.ALL_BRANCHES | Counts all near executed branches (not necessarily retired). | |
| 89H | 01H | BR_MISP_EXEC.COND | Qualify conditional near branch instructions mispredicted. | Must combine with umask 40H, 80H |
| 89H | 04H | BR_MISP_EXEC.INDIRECT_JMP_NON_CALL_RET | Qualify mispredicted indirect near branch instructions that are not calls nor returns. | Must combine with umask 80H |

**Table 19-2. Non-Architectural Performance Events In the Processor Core of the Intel® Core™ M Processors (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 89H | 08H | BR_MISP_EXEC.RETURN_NEAR | Qualify mispredicted indirect near branches that have a return mnemonic. | Must combine with umask 80H |
| 89H | 10H | BR_MISP_EXEC.DIRECT_NEAR_CALL | Qualify mispredicted unconditional near call branch instructions, excluding non call branch, executed. | Must combine with umask 80H |
| 89H | 20H | BR_MISP_EXEC.INDIRECT_NEAR_CALL | Qualify mispredicted indirect near calls, including both register and memory indirect, executed. | Must combine with umask 80H |
| 89H | 40H | BR_MISP_EXEC.NONTAKEN | Qualify mispredicted non-taken near branches executed. | Applicable to umask 01H only |
| 89H | 80H | BR_MISP_EXEC.TAKEN | Qualify mispredicted taken near branches executed. Must combine with 01H,02H, 04H, 08H, 10H, 20H. | |
| 89H | FFH | BR_MISP_EXEC.ALL_BRANCHES | Counts all near executed branches (not necessarily retired). | |
| 9CH | 01H | IDQ_UOPS_NOT_DELIVERED.CORE | Count number of non-delivered uops to RAT per thread. | Use Cmask to qualify uop b/w |
| A1H | 01H | UOPS_DISPATCHED_PORT.PORT_0 | Cycles which a Uop is dispatched on port 0 in this thread. | Set AnyThread to count per core |
| A1H | 02H | UOPS_DISPATCHED_PORT.PORT_1 | Cycles which a Uop is dispatched on port 1 in this thread. | Set AnyThread to count per core |
| A1H | 04H | UOPS_DISPATCHED_PORT.PORT_2 | Cycles which a uop is dispatched on port 2 in this thread. | Set AnyThread to count per core |
| A1H | 08H | UOPS_DISPATCHED_PORT.PORT_3 | Cycles which a uop is dispatched on port 3 in this thread. | Set AnyThread to count per core |
| A1H | 10H | UOPS_DISPATCHED_PORT.PORT_4 | Cycles which a uop is dispatched on port 4 in this thread. | Set AnyThread to count per core |
| A1H | 20H | UOPS_DISPATCHED_PORT.PORT_5 | Cycles which a uop is dispatched on port 5 in this thread. | Set AnyThread to count per core |
| A1H | 40H | UOPS_DISPATCHED_PORT.PORT_6 | Cycles which a Uop is dispatched on port 6 in this thread. | Set AnyThread to count per core |
| A1H | 80H | UOPS_DISPATCHED_PORT.PORT_7 | Cycles which a Uop is dispatched on port 7 in this thread | Set AnyThread to count per core |
| A2H | 01H | RESOURCE_STALLS.ANY | Cycles Allocation is stalled due to Resource Related reason. | |
| A2H | 04H | RESOURCE_STALLS.RS | Cycles stalled due to no eligible RS entry available. | |
| A2H | 08H | RESOURCE_STALLS.SB | Cycles stalled due to no store buffers available (not including draining form sync). | |
| A2H | 10H | RESOURCE_STALLS.ROB | Cycles stalled due to re-order buffer full. | |
| A8H | 01H | LSD.UOPS | Number of Uops delivered by the LSD. | |
| ABH | 02H | DSB2MITE_SWITCHES.PENALTY_CYCLES | Cycles of delay due to Decode Stream Buffer to MITE switches | |
| AEH | 01H | ITLB.ITLB_FLUSH | Counts the number of ITLB flushes, includes 4k/2M/4M pages. | |
| B0H | 01H | OFFCORE_REQUESTS.DEMAND_DATA_RD | Demand data read requests sent to uncore. | Use only when HTT is off |
| B0H | 02H | OFFCORE_REQUESTS.DEMAND_CODE_RD | Demand code read requests sent to uncore. | Use only when HTT is off |

Table 19-2. Non-Architectural Performance Events In the Processor Core of the Intel® Core™ M Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| B0H | 04H | OFFCORE_REQUESTS.DEMAND_RFO | Demand RFO read requests sent to uncore, including regular RFOs, locks, ItoM. | Use only when HTT is off |
| B0H | 08H | OFFCORE_REQUESTS.ALL_DATA_RD | Data read requests sent to uncore (demand and prefetch). | Use only when HTT is off |
| B1H | 01H | UOPS_EXECUTED.THREAD | Counts total number of uops to be executed per-logical-processor each cycle. | Use Cmask to count stall cycles |
| B1H | 02H | UOPS_EXECUTED.CORE | Counts total number of uops to be executed per-core each cycle. | Do not need to set ANY |
| B7H | 01H | OFF_CORE_RESPONSE_0 | see Section 18.9.5, "Off-core Response Performance Monitoring". | Requires MSR 01A6H |
| BBH | 01H | OFF_CORE_RESPONSE_1 | See Section 18.9.5, "Off-core Response Performance Monitoring". | Requires MSR 01A7H |
| BCH | 11H | PAGE_WALKER_LOADS.DTLB_L1 | Number of DTLB page walker loads that hit in the L1+FB. | |
| BCH | 21H | PAGE_WALKER_LOADS.ITLB_L1 | Number of ITLB page walker loads that hit in the L1+FB. | |
| BCH | 12H | PAGE_WALKER_LOADS.DTLB_L2 | Number of DTLB page walker loads that hit in the L2. | |
| BCH | 22H | PAGE_WALKER_LOADS.ITLB_L2 | Number of ITLB page walker loads that hit in the L2. | |
| BCH | 14H | PAGE_WALKER_LOADS.DTLB_L3 | Number of DTLB page walker loads that hit in the L3. | |
| BCH | 24H | PAGE_WALKER_LOADS.ITLB_L3 | Number of ITLB page walker loads that hit in the L3. | |
| BCH | 18H | PAGE_WALKER_LOADS.DTLB_MEMORY | Number of DTLB page walker loads from memory. | |
| C0H | 00H | INST_RETIRED.ANY_P | Number of instructions at retirement. | See Table 19-1 |
| C0H | 01H | INST_RETIRED.PREC_DIST | Precise instruction retired event with HW to reduce effect of PEBS shadow in IP distribution. | PMC1 only; |
| C0H | 02H | INST_RETIRED.X87 | FP operations retired. X87 FP operations that have no exceptions | |
| C1H | 08H | OTHER_ASSISTS.AVX_TO_SSE | Number of transitions from AVX-256 to legacy SSE when penalty applicable. | |
| C1H | 10H | OTHER_ASSISTS.SSE_TO_AVX | Number of transitions from SSE to AVX-256 when penalty applicable. | |
| C1H | 40H | OTHER_ASSISTS.ANY_WB_ASSIST | Number of microcode assists invoked by HW upon uop writeback. | |
| C2H | 01H | UOPS_RETIRED.ALL | Counts the number of micro-ops retired, Use cmask=1 and invert to count active cycles or stalled cycles. | Supports PEBS and DataLA, use Any=1 for core granular. |
| C2H | 02H | UOPS_RETIRED.RETIRE_SLOTS | Counts the number of retirement slots used each cycle. | Supports PEBS |
| C3H | 01H | MACHINE_CLEARS.CYCLES | Counts cycles while a machine clears. stalled forward progress of a logical processor or a processor core. | |
| C3H | 02H | MACHINE_CLEARS.MEMORY_ORDERING | Counts the number of machine clears due to memory order conflicts. | |
| C3H | 04H | MACHINE_CLEARS.SMC | Number of self-modifying-code machine clears detected. | |

**Table 19-2. Non-Architectural Performance Events In the Processor Core of the Intel® Core™ M Processors (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| C3H | 20H | MACHINE_CLEARS.MASKMOV | Counts the number of executed AVX masked load operations that refer to an illegal address range with the mask bits set to 0. | |
| C4H | 00H | BR_INST_RETIRED.ALL_BRANCHES | Branch instructions at retirement. | See Table 19-1 |
| C4H | 01H | BR_INST_RETIRED.CONDITIONAL | Counts the number of conditional branch instructions retired. | Supports PEBS |
| C4H | 02H | BR_INST_RETIRED.NEAR_CALL | Direct and indirect near call instructions retired. | Supports PEBS |
| C4H | 04H | BR_INST_RETIRED.ALL_BRANCHES | Counts the number of branch instructions retired. | Supports PEBS |
| C4H | 08H | BR_INST_RETIRED.NEAR_RETURN | Counts the number of near return instructions retired. | Supports PEBS |
| C4H | 10H | BR_INST_RETIRED.NOT_TAKEN | Counts the number of not taken branch instructions retired. | |
| C4H | 20H | BR_INST_RETIRED.NEAR_TAKEN | Number of near taken branches retired. | Supports PEBS |
| C4H | 40H | BR_INST_RETIRED.FAR_BRANCH | Number of far branches retired. | |
| C5H | 00H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted branch instructions at retirement | See Table 19-1 |
| C5H | 01H | BR_MISP_RETIRED.CONDITIONAL | Mispredicted conditional branch instructions retired. | Supports PEBS |
| C5H | 04H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted macro branch instructions retired. | Supports PEBS |
| CAH | 02H | FP_ASSIST.X87_OUTPUT | Number of X87 FP assists due to Output values. | |
| CAH | 04H | FP_ASSIST.X87_INPUT | Number of X87 FP assists due to input values. | |
| CAH | 08H | FP_ASSIST.SIMD_OUTPUT | Number of SIMD FP assists due to Output values. | |
| CAH | 10H | FP_ASSIST.SIMD_INPUT | Number of SIMD FP assists due to input values. | |
| CAH | 1EH | FP_ASSIST.ANY | Cycles with any input/output SSE* or FP assists. | |
| CCH | 20H | ROB_MISC_EVENTS.LBR_INSERTS | Count cases of saving new LBR records by hardware. | |
| CDH | 01H | MEM_TRANS_RETIRED.LOAD_LATENCY | Randomly sampled loads whose latency is above a user defined threshold. A small fraction of the overall loads are sampled due to randomization. | Specify threshold in MSR 3F6H |
| D0H | 01H | MEM_UOPS_RETIRED.LOADS | Qualify retired memory uops that are loads. Combine with umask 10H, 20H, 40H, 80H. | Supports PEBS and DataLA |
| D0H | 02H | MEM_UOPS_RETIRED.STORES | Qualify retired memory uops that are stores. Combine with umask 10H, 20H, 40H, 80H. | Supports PEBS and DataLA |
| D0H | 10H | MEM_UOPS_RETIRED.STLB_MISS | Qualify retired memory uops with STLB miss. Must combine with umask 01H, 02H, to produce counts. | Supports PEBS and DataLA |
| D0H | 40H | MEM_UOPS_RETIRED.SPLIT | Qualify retired memory uops with line split. Must combine with umask 01H, 02H, to produce counts. | Supports PEBS and DataLA |
| D0H | 80H | MEM_UOPS_RETIRED.ALL | Qualify any retired memory uops. Must combine with umask 01H, 02H, to produce counts. | Supports PEBS and DataLA |
| D1H | 01H | MEM_LOAD_UOPS_RETIRED.L1_HIT | Retired load uops with L1 cache hits as data sources. | Supports PEBS and DataLA |

Table 19-2. Non-Architectural Performance Events In the Processor Core of the Intel® Core™ M Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| D1H | 02H | MEM_LOAD_UOPS_RETIRED.L2_HIT | Retired load uops with L2 cache hits as data sources. | Supports PEBS and DataLA |
| D1H | 04H | MEM_LOAD_UOPS_RETIRED.L3_HIT | Retired load uops with L3 cache hits as data sources. | Supports PEBS and DataLA |
| D1H | 08H | MEM_LOAD_UOPS_RETIRED.L1_MISS | Retired load uops missed L1 cache as data sources. | Supports PEBS and DataLA |
| D1H | 10H | MEM_LOAD_UOPS_RETIRED.L2_MISS | Retired load uops missed L2. Unknown data source excluded. | Supports PEBS and DataLA |
| D1H | 20H | MEM_LOAD_UOPS_RETIRED.L3_MISS | Retired load uops missed L3. Excludes unknown data source . | Supports PEBS and DataLA |
| D1H | 40H | MEM_LOAD_UOPS_RETIRED.HIT_LFB | Retired load uops which data sources were load uops missed L1 but hit FB due to preceding miss to the same cache line with data not ready. | Supports PEBS and DataLA |
| D2H | 01H | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_MISS | Retired load uops which data sources were L3 hit and cross-core snoop missed in on-pkg core cache. | Supports PEBS and DataLA |
| D2H | 02H | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_HIT | Retired load uops which data sources were L3 and cross-core snoop hits in on-pkg core cache. | Supports PEBS and DataLA |
| D2H | 04H | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_HITM | Retired load uops which data sources were HitM responses from shared L3. | Supports PEBS and DataLA |
| D2H | 08H | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_NONE | Retired load uops which data sources were hits in L3 without snoops required. | Supports PEBS and DataLA |
| D3H | 01H | MEM_LOAD_UOPS_L3_MISS_RETIRED.LOCAL_DRAM | Retired load uops which data sources missed L3 but serviced from local dram. | Supports PEBS and DataLA. |
| F0H | 01H | L2_TRANS.DEMAND_DATA_RD | Demand Data Read requests that access L2 cache. | |
| F0H | 02H | L2_TRANS.RFO | RFO requests that access L2 cache. | |
| F0H | 04H | L2_TRANS.CODE_RD | L2 cache accesses when fetching instructions. | |
| F0H | 08H | L2_TRANS.ALL_PF | Any MLC or L3 HW prefetch accessing L2, including rejects. | |
| F0H | 10H | L2_TRANS.L1D_WB | L1D writebacks that access L2 cache. | |
| F0H | 20H | L2_TRANS.L2_FILL | L2 fill requests that access L2 cache. | |
| F0H | 40H | L2_TRANS.L2_WB | L2 writebacks that access L2 cache. | |
| F0H | 80H | L2_TRANS.ALL_REQUESTS | Transactions accessing L2 pipe. | |
| F1H | 01H | L2_LINES_IN.I | L2 cache lines in I state filling L2. | Counting does not cover rejects. |
| F1H | 02H | L2_LINES_IN.S | L2 cache lines in S state filling L2. | Counting does not cover rejects. |
| F1H | 04H | L2_LINES_IN.E | L2 cache lines in E state filling L2. | Counting does not cover rejects. |
| F1H | 07H | L2_LINES_IN.ALL | L2 cache lines filling L2. | Counting does not cover rejects. |
| F2H | 05H | L2_LINES_OUT.DEMAND_CLEAN | Clean L2 cache lines evicted by demand. | |

## 19.3 PERFORMANCE MONITORING EVENTS FOR THE 4TH GENERATION INTEL® CORE™ PROCESSORS

4th generation Intel® Core™ processors and Intel Xeon processor E3-1200 v3 product family are based on the Haswell microarchitecture. They support the architectural performance-monitoring events listed in Table 19-1. Non-architectural performance-monitoring events in the processor core are listed in Table 19-3. The events in Table 19-3 apply to processors with CPUID signature of DisplayFamily_DisplayModel encoding with the following values: 06_3CH, 06_45H and 06_46H. Table 19-4 lists performance events focused on supporting Intel TSX (see Section 18.11.5).

Additional information on event specifics (e.g. derivative events using specific IA32_PERFEVTSELx modifiers, limitations, special notes and recommendations) can be found at http://software.intel.com/en-us/forums/software-tuning-performance-optimization-platform-monitoring.

**Table 19-3. Non-Architectural Performance Events In the Processor Core of 4th Generation Intel® Core™ Processors**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 03H | 02H | LD_BLOCKS.STORE_FORWARD | loads blocked by overlapping with store buffer that cannot be forwarded . | |
| 03H | 08H | LD_BLOCKS.NO_SR | The number of times that split load operations are temporarily blocked because all resources for handling the split accesses are in use. | |
| 05H | 01H | MISALIGN_MEM_REF.LOADS | Speculative cache-line split load uops dispatched to L1D. | |
| 05H | 02H | MISALIGN_MEM_REF.STORES | Speculative cache-line split Store-address uops dispatched to L1D. | |
| 07H | 01H | LD_BLOCKS_PARTIAL.ADDRESS_ALIAS | False dependencies in MOB due to partial compare on address. | |
| 08H | 01H | DTLB_LOAD_MISSES.MISS_CAUSES_A_WALK | Misses in all TLB levels that cause a page walk of any page size. | |
| 08H | 02H | DTLB_LOAD_MISSES.WALK_COMPLETED_4K | Completed page walks due to demand load misses that caused 4K page walks in any TLB levels. | |
| 08H | 04H | DTLB_LOAD_MISSES.WALK_COMPLETED_2M_4M | Completed page walks due to demand load misses that caused 2M/4M page walks in any TLB levels. | |
| 08H | 0EH | DTLB_LOAD_MISSES.WALK_COMPLETED | Completed page walks in any TLB of any page size due to demand load misses | |
| 08H | 10H | DTLB_LOAD_MISSES.WALK_DURATION | Cycle PMH is busy with a walk. | |
| 08H | 20H | DTLB_LOAD_MISSES.STLB_HIT_4K | Load misses that missed DTLB but hit STLB (4K). | |
| 08H | 40H | DTLB_LOAD_MISSES.STLB_HIT_2M | Load misses that missed DTLB but hit STLB (2M). | |
| 08H | 60H | DTLB_LOAD_MISSES.STLB_HIT | Number of cache load STLB hits. No page walk. | |
| 08H | 80H | DTLB_LOAD_MISSES.PDE_CACHE_MISS | DTLB demand load misses with low part of linear-to-physical address translation missed | |
| 0DH | 03H | INT_MISC.RECOVERY_CYCLES | Cycles waiting to recover after Machine Clears except JEClear. Set Cmask= 1. | Set Edge to count occurrences |
| 0EH | 01H | UOPS_ISSUED.ANY | Increments each cycle the # of Uops issued by the RAT to RS.<br>Set Cmask = 1, Inv = 1, Any= 1to count stalled cycles of this core. | Set Cmask = 1, Inv = 1to count stalled cycles |

## Table 19-3. Non-Architectural Performance Events In the Processor Core of 4th Generation Intel® Core™ Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 0EH | 10H | UOPS_ISSUED.FLAGS_MERGE | Number of flags-merge uops allocated. Such uops adds delay. | |
| 0EH | 20H | UOPS_ISSUED.SLOW_LEA | Number of slow LEA or similar uops allocated. Such uop has 3 sources (e.g. 2 sources + immediate) regardless if as a result of LEA instruction or not. | |
| 0EH | 40H | UOPS_ISSUED.SINGLE_MUL | Number of multiply packed/scalar single precision uops allocated. | |
| 24H | 21H | L2_RQSTS.DEMAND_DATA_RD_MISS | Demand Data Read requests that missed L2, no rejects. | |
| 24H | 41H | L2_RQSTS.DEMAND_DATA_RD_HIT | Demand Data Read requests that hit L2 cache. | |
| 24H | E1H | L2_RQSTS.ALL_DEMAND_DATA_RD | Counts any demand and L1 HW prefetch data load requests to L2. | |
| 24H | 42H | L2_RQSTS.RFO_HIT | Counts the number of store RFO requests that hit the L2 cache. | |
| 24H | 22H | L2_RQSTS.RFO_MISS | Counts the number of store RFO requests that miss the L2 cache. | |
| 24H | E2H | L2_RQSTS.ALL_RFO | Counts all L2 store RFO requests. | |
| 24H | 44H | L2_RQSTS.CODE_RD_HIT | Number of instruction fetches that hit the L2 cache. | |
| 24H | 24H | L2_RQSTS.CODE_RD_MISS | Number of instruction fetches that missed the L2 cache. | |
| 24H | 27H | L2_RQSTS.ALL_DEMAND_MISS | Demand requests that miss L2 cache. | |
| 24H | E7H | L2_RQSTS.ALL_DEMAND_REFERENCES | Demand requests to L2 cache. | |
| 24H | E4H | L2_RQSTS.ALL_CODE_RD | Counts all L2 code requests. | |
| 24H | 50H | L2_RQSTS.L2_PF_HIT | Counts all L2 HW prefetcher requests that hit L2. | |
| 24H | 30H | L2_RQSTS.L2_PF_MISS | Counts all L2 HW prefetcher requests that missed L2. | |
| 24H | F8H | L2_RQSTS.ALL_PF | Counts all L2 HW prefetcher requests. | |
| 24H | 3FH | L2_RQSTS.MISS | All requests that missed L2. | |
| 24H | FFH | L2_RQSTS.REFERENCES | All requests to L2 cache. | |
| 27H | 50H | L2_DEMAND_RQSTS.WB_HIT | Not rejected writebacks that hit L2 cache | |
| 2EH | 4FH | LONGEST_LAT_CACHE.REFERENCE | This event counts requests originating from the core that reference a cache line in the last level cache. | see Table 19-1 |
| 2EH | 41H | LONGEST_LAT_CACHE.MISS | This event counts each cache miss condition for references to the last level cache. | see Table 19-1 |
| 3CH | 00H | CPU_CLK_UNHALTED.THREAD_P | Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling. | see Table 19-1 |
| 3CH | 01H | CPU_CLK_THREAD_UNHALTED.REF_XCLK | Increments at the frequency of XCLK (100 MHz) when not halted. | see Table 19-1 |

### Table 19-3. Non-Architectural Performance Events In the Processor Core of 4th Generation Intel® Core™ Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 48H | 01H | L1D_PEND_MISS.PENDING | Increments the number of outstanding L1D misses every cycle. Set Cmaks = 1 and Edge =1 to count occurrences. | Counter 2 only;<br>Set Cmask = 1 to count cycles. |
| 49H | 01H | DTLB_STORE_MISSES.MISS_CAUSES_A_WALK | Miss in all TLB levels causes an page walk of any page size (4K/2M/4M/1G). | |
| 49H | 02H | DTLB_STORE_MISSES.WALK_COMPLETED_4K | Completed page walks due to store misses in one or more TLB levels of 4K page structure. | |
| 49H | 04H | DTLB_STORE_MISSES.WALK_COMPLETED_2M_4M | Completed page walks due to store misses in one or more TLB levels of 2M/4M page structure. | |
| 49H | 0EH | DTLB_STORE_MISSES.WALK_COMPLETED | Completed page walks due to store miss in any TLB levels of any page size (4K/2M/4M/1G). | |
| 49H | 10H | DTLB_STORE_MISSES.WALK_DURATION | Cycles PMH is busy with this walk. | |
| 49H | 20H | DTLB_STORE_MISSES.STLB_HIT_4K | Store misses that missed DTLB but hit STLB (4K). | |
| 49H | 40H | DTLB_STORE_MISSES.STLB_HIT_2M | Store misses that missed DTLB but hit STLB (2M). | |
| 49H | 60H | DTLB_STORE_MISSES.STLB_HIT | Store operations that miss the first TLB level but hit the second and do not cause page walks. | |
| 49H | 80H | DTLB_STORE_MISSES.PDE_CACHE_MISS | DTLB store misses with low part of linear-to-physical address translation missed. | |
| 4CH | 01H | LOAD_HIT_PRE.SW_PF | Non-SW-prefetch load dispatches that hit fill buffer allocated for S/W prefetch. | |
| 4CH | 02H | LOAD_HIT_PRE.HW_PF | Non-SW-prefetch load dispatches that hit fill buffer allocated for H/W prefetch. | |
| 51H | 01H | L1D.REPLACEMENT | Counts the number of lines brought into the L1 data cache. | |
| 58H | 04H | MOVE_ELIMINATION.INT_NOT_ELIMINATED | Number of integer Move Elimination candidate uops that were not eliminated. | |
| 58H | 08H | MOVE_ELIMINATION.SIMD_NOT_ELIMINATED | Number of SIMD Move Elimination candidate uops that were not eliminated. | |
| 58H | 01H | MOVE_ELIMINATION.INT_ELIMINATED | Number of integer Move Elimination candidate uops that were eliminated. | |
| 58H | 02H | MOVE_ELIMINATION.SIMD_ELIMINATED | Number of SIMD Move Elimination candidate uops that were eliminated. | |
| 5CH | 01H | CPL_CYCLES.RING0 | Unhalted core cycles when the thread is in ring 0. | Use Edge to count transition |
| 5CH | 02H | CPL_CYCLES.RING123 | Unhalted core cycles when the thread is not in ring 0. | |
| 5EH | 01H | RS_EVENTS.EMPTY_CYCLES | Cycles the RS is empty for the thread. | |
| 60H | 01H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_DATA_RD | Offcore outstanding Demand Data Read transactions in SQ to uncore. Set Cmask=1 to count cycles. | Use only when HTT is off |
| 60H | 02H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_CODE_RD | Offcore outstanding Demand code Read transactions in SQ to uncore. Set Cmask=1 to count cycles. | Use only when HTT is off |
| 60H | 04H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_RFO | Offcore outstanding RFO store transactions in SQ to uncore. Set Cmask=1 to count cycles. | Use only when HTT is off |

## Table 19-3. Non-Architectural Performance Events In the Processor Core of 4th Generation Intel® Core™ Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 60H | 08H | OFFCORE_REQUESTS_OUTSTANDING.ALL_DATA_RD | Offcore outstanding cacheable data read transactions in SQ to uncore. Set Cmask=1 to count cycles. | Use only when HTT is off |
| 63H | 01H | LOCK_CYCLES.SPLIT_LOCK_UC_LOCK_DURATION | Cycles in which the L1D and L2 are locked, due to a UC lock or split lock. | |
| 63H | 02H | LOCK_CYCLES.CACHE_LOCK_DURATION | Cycles in which the L1D is locked. | |
| 79H | 02H | IDQ.EMPTY | Counts cycles the IDQ is empty. | |
| 79H | 04H | IDQ.MITE_UOPS | Increment each cycle # of uops delivered to IDQ from MITE path.<br>Set Cmask = 1 to count cycles. | Can combine Umask 04H and 20H |
| 79H | 08H | IDQ.DSB_UOPS | Increment each cycle. # of uops delivered to IDQ from DSB path.<br>Set Cmask = 1 to count cycles. | Can combine Umask 08H and 10H |
| 79H | 10H | IDQ.MS_DSB_UOPS | Increment each cycle # of uops delivered to IDQ when MS_busy by DSB. Set Cmask = 1 to count cycles. Add Edge=1 to count # of delivery. | Can combine Umask 04H, 08H |
| 79H | 20H | IDQ.MS_MITE_UOPS | Increment each cycle # of uops delivered to IDQ when MS_busy by MITE. Set Cmask = 1 to count cycles. | Can combine Umask 04H, 08H |
| 79H | 30H | IDQ.MS_UOPS | Increment each cycle # of uops delivered to IDQ from MS by either DSB or MITE. Set Cmask = 1 to count cycles. | Can combine Umask 04H, 08H |
| 79H | 18H | IDQ.ALL_DSB_CYCLES_ANY_UOPS | Counts cycles DSB is delivered at least one uops. Set Cmask = 1. | |
| 79H | 18H | IDQ.ALL_DSB_CYCLES_4_UOPS | Counts cycles DSB is delivered four uops. Set Cmask = 4. | |
| 79H | 24H | IDQ.ALL_MITE_CYCLES_ANY_UOPS | Counts cycles MITE is delivered at least one uops. Set Cmask = 1. | |
| 79H | 24H | IDQ.ALL_MITE_CYCLES_4_UOPS | Counts cycles MITE is delivered four uops. Set Cmask = 4. | |
| 79H | 3CH | IDQ.MITE_ALL_UOPS | # of uops delivered to IDQ from any path. | |
| 80H | 02H | ICACHE.MISSES | Number of Instruction Cache, Streaming Buffer and Victim Cache Misses. Includes UC accesses. | |
| 85H | 01H | ITLB_MISSES.MISS_CAUSES_A_WALK | Misses in ITLB that causes a page walk of any page size. | |
| 85H | 02H | ITLB_MISSES.WALK_COMPLETED_4K | Completed page walks due to misses in ITLB 4K page entries. | |
| 85H | 04H | ITLB_MISSES.WALK_COMPLETED_2M_4M | Completed page walks due to misses in ITLB 2M/4M page entries. | |
| 85H | 0EH | ITLB_MISSES.WALK_COMPLETED | Completed page walks in ITLB of any page size. | |
| 85H | 10H | ITLB_MISSES.WALK_DURATION | Cycle PMH is busy with a walk. | |
| 85H | 20H | ITLB_MISSES.STLB_HIT_4K | ITLB misses that hit STLB (4K). | |
| 85H | 40H | ITLB_MISSES.STLB_HIT_2M | ITLB misses that hit STLB (2M). | |

### Table 19-3. Non-Architectural Performance Events In the Processor Core of 4th Generation Intel® Core™ Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 85H | 60H | ITLB_MISSES.STLB_HIT | ITLB misses that hit STLB. No page walk. | |
| 87H | 01H | ILD_STALL.LCP | Stalls caused by changing prefix length of the instruction. | |
| 87H | 04H | ILD_STALL.IQ_FULL | Stall cycles due to IQ is full. | |
| 88H | 01H | BR_INST_EXEC.COND | Qualify conditional near branch instructions executed, but not necessarily retired. | Must combine with umask 40H, 80H |
| 88H | 02H | BR_INST_EXEC.DIRECT_JMP | Qualify all unconditional near branch instructions excluding calls and indirect branches. | Must combine with umask 80H |
| 88H | 04H | BR_INST_EXEC.INDIRECT_JMP_NON_CALL_RET | Qualify executed indirect near branch instructions that are not calls nor returns. | Must combine with umask 80H |
| 88H | 08H | BR_INST_EXEC.RETURN_NEAR | Qualify indirect near branches that have a return mnemonic. | Must combine with umask 80H |
| 88H | 10H | BR_INST_EXEC.DIRECT_NEAR_CALL | Qualify unconditional near call branch instructions, excluding non call branch, executed. | Must combine with umask 80H |
| 88H | 20H | BR_INST_EXEC.INDIRECT_NEAR_CALL | Qualify indirect near calls, including both register and memory indirect, executed. | Must combine with umask 80H |
| 88H | 40H | BR_INST_EXEC.NONTAKEN | Qualify non-taken near branches executed. | Applicable to umask 01H only |
| 88H | 80H | BR_INST_EXEC.TAKEN | Qualify taken near branches executed. Must combine with 01H,02H, 04H, 08H, 10H, 20H. | |
| 88H | FFH | BR_INST_EXEC.ALL_BRANCHES | Counts all near executed branches (not necessarily retired). | |
| 89H | 01H | BR_MISP_EXEC.COND | Qualify conditional near branch instructions mispredicted. | Must combine with umask 40H, 80H |
| 89H | 04H | BR_MISP_EXEC.INDIRECT_JMP_NON_CALL_RET | Qualify mispredicted indirect near branch instructions that are not calls nor returns. | Must combine with umask 80H |
| 89H | 08H | BR_MISP_EXEC.RETURN_NEAR | Qualify mispredicted indirect near branches that have a return mnemonic. | Must combine with umask 80H |
| 89H | 10H | BR_MISP_EXEC.DIRECT_NEAR_CALL | Qualify mispredicted unconditional near call branch instructions, excluding non call branch, executed. | Must combine with umask 80H |
| 89H | 20H | BR_MISP_EXEC.INDIRECT_NEAR_CALL | Qualify mispredicted indirect near calls, including both register and memory indirect, executed. | Must combine with umask 80H |
| 89H | 40H | BR_MISP_EXEC.NONTAKEN | Qualify mispredicted non-taken near branches executed. | Applicable to umask 01H only |
| 89H | 80H | BR_MISP_EXEC.TAKEN | Qualify mispredicted taken near branches executed. Must combine with 01H,02H, 04H, 08H, 10H, 20H. | |
| 89H | FFH | BR_MISP_EXEC.ALL_BRANCHES | Counts all near executed branches (not necessarily retired). | |
| 9CH | 01H | IDQ_UOPS_NOT_DELIVERED.CORE | Count number of non-delivered uops to RAT per thread. | Use Cmask to qualify uop b/w |
| A1H | 01H | UOPS_EXECUTED_PORT.PORT_0 | Cycles which a Uop is dispatched on port 0 in this thread. | Set AnyThread to count per core |
| A1H | 02H | UOPS_EXECUTED_PORT.PORT_1 | Cycles which a Uop is dispatched on port 1 in this thread. | Set AnyThread to count per core |

## Table 19-3. Non-Architectural Performance Events In the Processor Core of 4th Generation Intel® Core™ Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| A1H | 04H | UOPS_EXECUTED_PORT.PORT_2 | Cycles which a uop is dispatched on port 2 in this thread. | Set AnyThread to count per core |
| A1H | 08H | UOPS_EXECUTED_PORT.PORT_3 | Cycles which a uop is dispatched on port 3 in this thread. | Set AnyThread to count per core |
| A1H | 10H | UOPS_EXECUTED_PORT.PORT_4 | Cycles which a uop is dispatched on port 4 in this thread. | Set AnyThread to count per core |
| A1H | 20H | UOPS_EXECUTED_PORT.PORT_5 | Cycles which a uop is dispatched on port 5 in this thread. | Set AnyThread to count per core |
| A1H | 40H | UOPS_EXECUTED_PORT.PORT_6 | Cycles which a Uop is dispatched on port 6 in this thread. | Set AnyThread to count per core |
| A1H | 80H | UOPS_EXECUTED_PORT.PORT_7 | Cycles which a Uop is dispatched on port 7 in this thread | Set AnyThread to count per core |
| A2H | 01H | RESOURCE_STALLS.ANY | Cycles Allocation is stalled due to Resource Related reason. | |
| A2H | 04H | RESOURCE_STALLS.RS | Cycles stalled due to no eligible RS entry available. | |
| A2H | 08H | RESOURCE_STALLS.SB | Cycles stalled due to no store buffers available (not including draining form sync). | |
| A2H | 10H | RESOURCE_STALLS.ROB | Cycles stalled due to re-order buffer full. | |
| A3H | 01H | CYCLE_ACTIVITY.CYCLES_L2_PENDING | Cycles with pending L2 miss loads. Set Cmask=2 to count cycle. | Use only when HTT is off |
| A3H | 02H | CYCLE_ACTIVITY.CYCLES_LDM_PENDING | Cycles with pending memory loads. Set Cmask=2 to count cycle. | |
| A3H | 05H | CYCLE_ACTIVITY.STALLS_L2_PENDING | Number of loads missed L2. | Use only when HTT is off |
| A3H | 08H | CYCLE_ACTIVITY.CYCLES_L1D_PENDING | Cycles with pending L1 data cache miss loads. Set Cmask=8 to count cycle. | PMC2 only |
| A3H | 0CH | CYCLE_ACTIVITY.STALLS_L1D_PENDING | Execution stalls due to L1 data cache miss loads. Set Cmask=0CH. | PMC2 only |
| A8H | 01H | LSD.UOPS | Number of Uops delivered by the LSD. | |
| AEH | 01H | ITLB.ITLB_FLUSH | Counts the number of ITLB flushes, includes 4k/2M/4M pages. | |
| B0H | 01H | OFFCORE_REQUESTS.DEMAND_DATA_RD | Demand data read requests sent to uncore. | Use only when HTT is off |
| B0H | 02H | OFFCORE_REQUESTS.DEMAND_CODE_RD | Demand code read requests sent to uncore. | Use only when HTT is off |
| B0H | 04H | OFFCORE_REQUESTS.DEMAND_RFO | Demand RFO read requests sent to uncore, including regular RFOs, locks, ItoM. | Use only when HTT is off |
| B0H | 08H | OFFCORE_REQUESTS.ALL_DATA_RD | Data read requests sent to uncore (demand and prefetch). | Use only when HTT is off |
| B1H | 02H | UOPS_EXECUTED.CORE | Counts total number of uops to be executed per-core each cycle. | Do not need to set ANY |
| B7H | 01H | OFF_CORE_RESPONSE_0 | see Section 18.9.5, "Off-core Response Performance Monitoring". | Requires MSR 01A6H |
| BBH | 01H | OFF_CORE_RESPONSE_1 | See Section 18.9.5, "Off-core Response Performance Monitoring". | Requires MSR 01A7H |

### Table 19-3. Non-Architectural Performance Events In the Processor Core of 4th Generation Intel® Core™ Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| BCH | 11H | PAGE_WALKER_LOADS.DTLB_L1 | Number of DTLB page walker loads that hit in the L1+FB. | |
| BCH | 21H | PAGE_WALKER_LOADS.ITLB_L1 | Number of ITLB page walker loads that hit in the L1+FB. | |
| BCH | 12H | PAGE_WALKER_LOADS.DTLB_L2 | Number of DTLB page walker loads that hit in the L2. | |
| BCH | 22H | PAGE_WALKER_LOADS.ITLB_L2 | Number of ITLB page walker loads that hit in the L2. | |
| BCH | 14H | PAGE_WALKER_LOADS.DTLB_L3 | Number of DTLB page walker loads that hit in the L3. | |
| BCH | 24H | PAGE_WALKER_LOADS.ITLB_L3 | Number of ITLB page walker loads that hit in the L3. | |
| BCH | 18H | PAGE_WALKER_LOADS.DTLB_MEMORY | Number of DTLB page walker loads from memory. | |
| BCH | 28H | PAGE_WALKER_LOADS.ITLB_MEMORY | Number of ITLB page walker loads from memory. | |
| BDH | 01H | TLB_FLUSH.DTLB_THREAD | DTLB flush attempts of the thread-specific entries. | |
| BDH | 20H | TLB_FLUSH.STLB_ANY | Count number of STLB flush attempts. | |
| C0H | 00H | INST_RETIRED.ANY_P | Number of instructions at retirement. | See Table 19-1 |
| C0H | 01H | INST_RETIRED.PREC_DIST | Precise instruction retired event with HW to reduce effect of PEBS shadow in IP distribution. | PMC1 only; |
| C1H | 08H | OTHER_ASSISTS.AVX_TO_SSE | Number of transitions from AVX-256 to legacy SSE when penalty applicable. | |
| C1H | 10H | OTHER_ASSISTS.SSE_TO_AVX | Number of transitions from SSE to AVX-256 when penalty applicable. | |
| C1H | 40H | OTHER_ASSISTS.ANY_WB_ASSIST | Number of microcode assists invoked by HW upon uop writeback. | |
| C2H | 01H | UOPS_RETIRED.ALL | Counts the number of micro-ops retired, Use cmask=1 and invert to count active cycles or stalled cycles. | Supports PEBS and DataLA, use Any=1 for core granular. |
| C2H | 02H | UOPS_RETIRED.RETIRE_SLOTS | Counts the number of retirement slots used each cycle. | Supports PEBS |
| C3H | 02H | MACHINE_CLEARS.MEMORY_ORDERING | Counts the number of machine clears due to memory order conflicts. | |
| C3H | 04H | MACHINE_CLEARS.SMC | Number of self-modifying-code machine clears detected. | |
| C3H | 20H | MACHINE_CLEARS.MASKMOV | Counts the number of executed AVX masked load operations that refer to an illegal address range with the mask bits set to 0. | |
| C4H | 00H | BR_INST_RETIRED.ALL_BRANCHES | Branch instructions at retirement. | See Table 19-1 |
| C4H | 01H | BR_INST_RETIRED.CONDITIONAL | Counts the number of conditional branch instructions retired. | Supports PEBS |
| C4H | 02H | BR_INST_RETIRED.NEAR_CALL | Direct and indirect near call instructions retired. | Supports PEBS |
| C4H | 04H | BR_INST_RETIRED.ALL_BRANCHES | Counts the number of branch instructions retired. | Supports PEBS |
| C4H | 08H | BR_INST_RETIRED.NEAR_RETURN | Counts the number of near return instructions retired. | Supports PEBS |

## Table 19-3. Non-Architectural Performance Events In the Processor Core of 4th Generation Intel® Core™ Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| C4H | 10H | BR_INST_RETIRED.NOT_TAKEN | Counts the number of not taken branch instructions retired. | |
| C4H | 20H | BR_INST_RETIRED.NEAR_TAKEN | Number of near taken branches retired. | Supports PEBS |
| C4H | 40H | BR_INST_RETIRED.FAR_BRANCH | Number of far branches retired. | |
| C5H | 00H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted branch instructions at retirement | See Table 19-1 |
| C5H | 01H | BR_MISP_RETIRED.CONDITIONAL | Mispredicted conditional branch instructions retired. | Supports PEBS |
| C5H | 04H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted macro branch instructions retired. | Supports PEBS |
| C5H | 20H | BR_MISP_RETIRED.NEAR_TAKEN | Number of near branch instructions retired that were taken but mispredicted. | |
| CAH | 02H | FP_ASSIST.X87_OUTPUT | Number of X87 FP assists due to Output values. | |
| CAH | 04H | FP_ASSIST.X87_INPUT | Number of X87 FP assists due to input values. | |
| CAH | 08H | FP_ASSIST.SIMD_OUTPUT | Number of SIMD FP assists due to Output values. | |
| CAH | 10H | FP_ASSIST.SIMD_INPUT | Number of SIMD FP assists due to input values. | |
| CAH | 1EH | FP_ASSIST.ANY | Cycles with any input/output SSE* or FP assists. | |
| CCH | 20H | ROB_MISC_EVENTS.LBR_INSERTS | Count cases of saving new LBR records by hardware. | |
| CDH | 01H | MEM_TRANS_RETIRED.LOAD_LATENCY | Randomly sampled loads whose latency is above a user defined threshold. A small fraction of the overall loads are sampled due to randomization. | Specify threshold in MSR 3F6H |
| D0H | 01H | MEM_UOPS_RETIRED.LOADS | Qualify retired memory uops that are loads. Combine with umask 10H, 20H, 40H, 80H. | Supports PEBS and DataLA |
| D0H | 10H | MEM_UOPS_RETIRED.STLB_MISS | Qualify retired memory uops with STLB miss. Must combine with umask 01H, 02H, to produce counts. | Supports PEBS and DataLA |
| D0H | 40H | MEM_UOPS_RETIRED.SPLIT | Qualify retired memory uops with line split. Must combine with umask 01H, 02H, to produce counts. | Supports PEBS and DataLA |
| D0H | 80H | MEM_UOPS_RETIRED.ALL | Qualify any retired memory uops. Must combine with umask 01H, 02H, to produce counts. | Supports PEBS and DataLA |
| D1H | 01H | MEM_LOAD_UOPS_RETIRED.L1_HIT | Retired load uops with L1 cache hits as data sources. | Supports PEBS and DataLA |
| D1H | 02H | MEM_LOAD_UOPS_RETIRED.L2_HIT | Retired load uops with L2 cache hits as data sources. | Supports PEBS and DataLA |
| D1H | 04H | MEM_LOAD_UOPS_RETIRED.L3_HIT | Retired load uops with L3 cache hits as data sources. | Supports PEBS and DataLA |
| D1H | 08H | MEM_LOAD_UOPS_RETIRED.L1_MISS | Retired load uops missed L1 cache as data sources. | Supports PEBS and DataLA |
| D1H | 10H | MEM_LOAD_UOPS_RETIRED.L2_MISS | Retired load uops missed L2. Unknown data source excluded. | Supports PEBS and DataLA |
| D1H | 20H | MEM_LOAD_UOPS_RETIRED.L3_MISS | Retired load uops missed L3. Excludes unknown data source . | Supports PEBS and DataLA |

### Table 19-3. Non-Architectural Performance Events In the Processor Core of 4th Generation Intel® Core™ Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| D1H | 40H | MEM_LOAD_UOPS_RETIRED.HIT_LFB | Retired load uops which data sources were load uops missed L1 but hit FB due to preceding miss to the same cache line with data not ready. | Supports PEBS and DataLA |
| D2H | 01H | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_MISS | Retired load uops which data sources were L3 hit and cross-core snoop missed in on-pkg core cache. | Supports PEBS and DataLA |
| D2H | 02H | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_HIT | Retired load uops which data sources were L3 and cross-core snoop hits in on-pkg core cache. | Supports PEBS and DataLA |
| D2H | 04H | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_HITM | Retired load uops which data sources were HitM responses from shared L3. | Supports PEBS and DataLA |
| D2H | 08H | MEM_LOAD_UOPS_L3_HIT_RETIRED.XSNP_NONE | Retired load uops which data sources were hits in L3 without snoops required. | Supports PEBS and DataLA |
| D3H | 01H | MEM_LOAD_UOPS_L3_MISS_RETIRED.LOCAL_DRAM | Retired load uops which data sources missed L3 but serviced from local dram. | Supports PEBS and DataLA. |
| E6H | 1FH | BACLEARS.ANY | Number of front end re-steers due to BPU misprediction. | |
| F0H | 01H | L2_TRANS.DEMAND_DATA_RD | Demand Data Read requests that access L2 cache. | |
| F0H | 02H | L2_TRANS.RFO | RFO requests that access L2 cache. | |
| F0H | 04H | L2_TRANS.CODE_RD | L2 cache accesses when fetching instructions. | |
| F0H | 08H | L2_TRANS.ALL_PF | Any MLC or L3 HW prefetch accessing L2, including rejects. | |
| F0H | 10H | L2_TRANS.L1D_WB | L1D writebacks that access L2 cache. | |
| F0H | 20H | L2_TRANS.L2_FILL | L2 fill requests that access L2 cache. | |
| F0H | 40H | L2_TRANS.L2_WB | L2 writebacks that access L2 cache. | |
| F0H | 80H | L2_TRANS.ALL_REQUESTS | Transactions accessing L2 pipe. | |
| F1H | 01H | L2_LINES_IN.I | L2 cache lines in I state filling L2. | Counting does not cover rejects. |
| F1H | 02H | L2_LINES_IN.S | L2 cache lines in S state filling L2. | Counting does not cover rejects. |
| F1H | 04H | L2_LINES_IN.E | L2 cache lines in E state filling L2. | Counting does not cover rejects. |
| F1H | 07H | L2_LINES_IN.ALL | L2 cache lines filling L2. | Counting does not cover rejects. |
| F2H | 05H | L2_LINES_OUT.DEMAND_CLEAN | Clean L2 cache lines evicted by demand. | |
| F2H | 06H | L2_LINES_OUT.DEMAND_DIRTY | Dirty L2 cache lines evicted by demand. | |

### Table 19-4. Intel TSX Performance Events in processors based on Haswell Microarchitecture

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 54H | 01H | TX_MEM.ABORT_CONFLICT | Number of times a transactional abort was signaled due to a data conflict on a transactionally accessed address | |
| 54H | 02H | TX_MEM.ABORT_CAPACITY_WRITE | Number of times a transactional abort was signaled due to a data capacity limitation for transactional writes | |

Table 19-4. Intel TSX Performance Events in processors based on Haswell Microarchitecture

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 54H | 04H | TX_MEM.ABORT_HLE_STORE_TO_ELIDED_LOCK | Number of times a HLE transactional region aborted due to a non XRELEASE prefixed instruction writing to an elided lock in the elision buffer | |
| 54H | 08H | TX_MEM.ABORT_HLE_ELISION_BUFFER_NOT_EMPTY | Number of times an HLE transactional execution aborted due to NoAllocatedElisionBuffer being non-zero. | |
| 54H | 10H | TX_MEM.ABORT_HLE_ELISION_BUFFER_MISMATCH | Number of times an HLE transactional execution aborted due to XRELEASE lock not satisfying the address and value requirements in the elision buffer. | |
| 54H | 20H | TX_MEM.ABORT_HLE_ELISION_BUFFER_UNSUPPORTED_ALIGNMENT | Number of times an HLE transactional execution aborted due to an unsupported read alignment from the elision buffer. | |
| 54H | 40H | TX_MEM.HLE_ELISION_BUFFER_FULL | Number of times HLE lock could not be elided due to ElisionBufferAvailable being zero. | |
| 5DH | 01H | TX_EXEC.MISC1 | Counts the number of times a class of instructions that may cause a transactional abort was executed. Since this is the count of execution, it may not always cause a transactional abort. | |
| 5DH | 02H | TX_EXEC.MISC2 | Counts the number of times a class of instructions (e.g. vzeroupper) that may cause a transactional abort was executed inside a transactional region | |
| 5DH | 04H | TX_EXEC.MISC3 | Counts the number of times an instruction execution caused the transactional nest count supported to be exceeded | |
| 5DH | 08H | TX_EXEC.MISC4 | Counts the number of times an XBEGIN instruction was executed inside an HLE transactional region | |
| 5DH | 10H | TX_EXEC.MISC5 | Counts the number of times an instruction with HLE-XACQUIRE semantic was executed inside an RTM transactional region | |
| C8H | 01H | HLE_RETIRED.START | Number of times an HLE execution started. | IF HLE is supported |
| C8H | 02H | HLE_RETIRED.COMMIT | Number of times an HLE execution successfully committed | |
| C8H | 04H | HLE_RETIRED.ABORTED | Number of times an HLE execution aborted due to any reasons (multiple categories may count as one). Supports PEBS | |
| C8H | 08H | HLE_RETIRED.ABORTED_MISC1 | Number of times an HLE execution aborted due to various memory events (e.g. read/write capacity and conflicts) | |
| C8H | 10H | HLE_RETIRED.ABORTED_MISC2 | Number of times an HLE execution aborted due to uncommon conditions | |
| C8H | 20H | HLE_RETIRED.ABORTED_MISC3 | Number of times an HLE execution aborted due to HLE-unfriendly instructions | |
| C8H | 40H | HLE_RETIRED.ABORTED_MISC4 | Number of times an HLE execution aborted due to incompatible memory type | |
| C8H | 80H | HLE_RETIRED.ABORTED_MISC5 | Number of times an HLE execution aborted due to none of the previous 4 categories (e.g. interrupts) | |

### Table 19-4. Intel TSX Performance Events in processors based on Haswell Microarchitecture

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| C9H | 01H | RTM_RETIRED.START | Number of times an RTM execution started. | IF RTM is supported |
| C9H | 02H | RTM_RETIRED.COMMIT | Number of times an RTM execution successfully committed | |
| C9H | 04H | RTM_RETIRED.ABORTED | Number of times an RTM execution aborted due to any reasons (multiple categories may count as one). Supports PEBS | |
| C9H | 08H | RTM_RETIRED.ABORTED_MISC1 | Number of times an RTM execution aborted due to various memory events (e.g. read/write capacity and conflicts) | IF RTM is supported |
| C9H | 10H | RTM_RETIRED.ABORTED_MISC2 | Number of times an RTM execution aborted due to uncommon conditions | |
| C9H | 20H | RTM_RETIRED.ABORTED_MISC3 | Number of times an RTM execution aborted due to HLE-unfriendly instructions | |
| C9H | 40H | RTM_RETIRED.ABORTED_MISC4 | Number of times an RTM execution aborted due to incompatible memory type | |
| C9H | 80H | RTM_RETIRED.ABORTED_MISC5 | Number of times an RTM execution aborted due to none of the previous 4 categories (e.g. interrupt) | |

Non-architectural performance monitoring events that are located in the uncore sub-system are implementation specific between different platforms using processors based on Haswell microarchitecture and with different DisplayFamily_DisplayModel signatures. Processors with CPUID signature of DisplayFamily_DisplayModel 06_3CH and 06_45H support performance events listed in Table 19-5.

### Table 19-5. Non-Architectural Uncore Performance Events In the 4th Generation Intel® Core™ Processors

| Event Num.[1] | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 22H | 01H | UNC_CBO_XSNP_RESPONSE.MISS | A snoop misses in some processor core. | Must combine with one of the umask values of 20H, 40H, 80H |
| 22H | 02H | UNC_CBO_XSNP_RESPONSE.INVAL | A snoop invalidates a non-modified line in some processor core. | |
| 22H | 04H | UNC_CBO_XSNP_RESPONSE.HIT | A snoop hits a non-modified line in some processor core. | |
| 22H | 08H | UNC_CBO_XSNP_RESPONSE.HITM | A snoop hits a modified line in some processor core. | |
| 22H | 10H | UNC_CBO_XSNP_RESPONSE.INVAL_M | A snoop invalidates a modified line in some processor core. | |
| 22H | 20H | UNC_CBO_XSNP_RESPONSE.EXTERNAL_FILTER | Filter on cross-core snoops initiated by this Cbox due to external snoop request. | Must combine with at least one of 01H, 02H, 04H, 08H, 10H |
| 22H | 40H | UNC_CBO_XSNP_RESPONSE.XCORE_FILTER | Filter on cross-core snoops initiated by this Cbox due to processor core memory request. | |
| 22H | 80H | UNC_CBO_XSNP_RESPONSE.EVICTION_FILTER | Filter on cross-core snoops initiated by this Cbox due to L3 eviction. | |

Table 19-5. Non-Architectural Uncore Performance Events In the 4th Generation Intel® Core™ Processors (Contd.)

| Event Num.[1] | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 34H | 01H | UNC_CBO_CACHE_LOOKUP.M | L3 lookup request that access cache and found line in M-state. | Must combine with one of the umask values of 10H, 20H, 40H, 80H |
| 34H | 06H | UNC_CBO_CACHE_LOOKUP.ES | L3 lookup request that access cache and found line in E or S state. | |
| 34H | 08H | UNC_CBO_CACHE_LOOKUP.I | L3 lookup request that access cache and found line in I-state. | |
| 34H | 10H | UNC_CBO_CACHE_LOOKUP.READ_FILTER | Filter on processor core initiated cacheable read requests. Must combine with at least one of 01H, 02H, 04H, 08H. | |
| 34H | 20H | UNC_CBO_CACHE_LOOKUP.WRITE_FILTER | Filter on processor core initiated cacheable write requests. Must combine with at least one of 01H, 02H, 04H, 08H. | |
| 34H | 40H | UNC_CBO_CACHE_LOOKUP.EXTSNP_FILTER | Filter on external snoop requests. Must combine with at least one of 01H, 02H, 04H, 08H. | |
| 34H | 80H | UNC_CBO_CACHE_LOOKUP.ANY_REQUEST_FILTER | Filter on any IRQ or IPQ initiated requests including uncacheable, non-coherent requests. Must combine with at least one of 01H, 02H, 04H, 08H. | |
| 80H | 01H | UNC_ARB_TRK_OCCUPANCY.ALL | Counts cycles weighted by the number of requests waiting for data returning from the memory controller. Accounts for coherent and non-coherent requests initiated by IA cores, processor graphic units, or L3. | Counter 0 only |
| 81H | 01H | UNC_ARB_TRK_REQUEST.ALL | Counts the number of coherent and in-coherent requests initiated by IA cores, processor graphic units, or L3. | |
| 81H | 20H | UNC_ARB_TRK_REQUEST.WRITES | Counts the number of allocated write entries, include full, partial, and L3 evictions. | |
| 81H | 80H | UNC_ARB_TRK_REQUEST.EVICTIONS | Counts the number of L3 evictions allocated. | |
| 83H | 01H | UNC_ARB_COH_TRK_OCCUPANCY.ALL | Cycles weighted by number of requests pending in Coherency Tracker. | Counter 0 only |
| 84H | 01H | UNC_ARB_COH_TRK_REQUEST.ALL | Number of requests allocated in Coherency Tracker. | |

NOTES:

1. The uncore events must be programmed using MSRs located in specific performance monitoring units in the uncore. UNC_CBO* events are supported using MSR_UNC_CBO* MSRs; UNC_ARB* events are supported using MSR_UNC_ARB*MSRs.

### 19.3.1 Performance Monitoring Events in the Processor Core of Intel Xeon Processor E5 v3 Family

Non-architectural performance monitoring events in the processor core that are applicable only to Intel Xeon processor E5 v3 family based on the Haswell-E microarchitecture, with CPUID signature of DisplayFamily_DisplayModel 06_3FH, are listed in Table 19-8.

**Table 19-6. Non-Architectural Performance Events Applicable only to the Processor Core of Intel® Xeon® Processor E5 v3 Family**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| D3H | 04H | MEM_LOAD_UOPS_L3_MISS_RETIRED.REMOTE_DRAM | Retired load uops whose data sources was remote DRAM (snoop not needed, Snoop Miss). | Supports PEBS |
| D3H | 10H | MEM_LOAD_UOPS_L3_MISS_RETIRED.REMOTE_HITM | Retired load uops whose data sources was remote cache HITM. | Supports PEBS |
| D3H | 20H | MEM_LOAD_UOPS_L3_MISS_RETIRED.REMOTE_FWD | Retired load uops whose data sources was forwards from a remote cache. | Supports PEBS |

## 19.4 PERFORMANCE MONITORING EVENTS FOR 3RD GENERATION INTEL® CORE™ PROCESSORS

3rd generation Intel® Core™ processors and Intel Xeon processor E3-1200 v2 product family are based on Intel microarchitecture code name Ivy Bridge. They support architectural performance-monitoring events listed in Table 19-1. Non-architectural performance-monitoring events in the processor core are listed in Table 19-7. The events in Table 19-7 apply to processors with CPUID signature of DisplayFamily_DisplayModel encoding with the following values: 06_3AH.

Additional informations on event specifics (e.g. derivative events using specific IA32_PERFEVTSELx modifiers, limitations, special notes and recommendations) can be found at http://software.intel.com/en-us/forums/software-tuning-performance-optimization-platform-monitoring.

**Table 19-7. Non-Architectural Performance Events In the Processor Core of 3rd Generation Intel® Core™ i7, i5, i3 Processors**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 03H | 02H | LD_BLOCKS.STORE_FORWARD | loads blocked by overlapping with store buffer that cannot be forwarded . | |
| 03H | 08H | LD_BLOCKS.NO_SR | The number of times that split load operations are temporarily blocked because all resources for handling the split accesses are in use. | |
| 05H | 01H | MISALIGN_MEM_REF.LOADS | Speculative cache-line split load uops dispatched to L1D. | |
| 05H | 02H | MISALIGN_MEM_REF.STORES | Speculative cache-line split Store-address uops dispatched to L1D. | |
| 07H | 01H | LD_BLOCKS_PARTIAL.ADDRESS_ALIAS | False dependencies in MOB due to partial compare on address. | |
| 08H | 81H | DTLB_LOAD_MISSES.MISS_CAUSES_A_WALK | Misses in all TLB levels that cause a page walk of any page size from demand loads. | |
| 08H | 82H | DTLB_LOAD_MISSES.WALK_COMPLETED | Misses in all TLB levels that caused page walk completed of any size by demand loads. | |
| 08H | 84H | DTLB_LOAD_MISSES.WALK_DURATION | Cycle PMH is busy with a walk due to demand loads. | |
| 08H | 88H | DTLB_LOAD_MISSES.LARGE_PAGE_WALK_DURATION | Page walk for a large page completed for Demand load | |

## Table 19-7. Non-Architectural Performance Events In the Processor Core of 3rd Generation Intel® Core™ i7, i5, i3 Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 0EH | 01H | UOPS_ISSUED.ANY | Increments each cycle the # of Uops issued by the RAT to RS.<br>Set Cmask = 1, Inv = 1, Any= 1to count stalled cycles of this core. | Set Cmask = 1, Inv = 1to count stalled cycles |
| 0EH | 10H | UOPS_ISSUED.FLAGS_MERGE | Number of flags-merge uops allocated. Such uops adds delay. | |
| 0EH | 20H | UOPS_ISSUED.SLOW_LEA | Number of slow LEA or similar uops allocated. Such uop has 3 sources (e.g. 2 sources + immediate) regardless if as a result of LEA instruction or not. | |
| 0EH | 40H | UOPS_ISSUED.SINGLE_MUL | Number of multiply packed/scalar single precision uops allocated. | |
| 10H | 01H | FP_COMP_OPS_EXE.X87 | Counts number of X87 uops executed. | |
| 10H | 10H | FP_COMP_OPS_EXE.SSE_FP_PACKED_DOUBLE | Counts number of SSE* or AVX-128 double precision FP packed uops executed. | |
| 10H | 20H | FP_COMP_OPS_EXE.SSE_FP_SCALAR_SINGLE | Counts number of SSE* or AVX-128 single precision FP scalar uops executed. | |
| 10H | 40H | FP_COMP_OPS_EXE.SSE_PACKED SINGLE | Counts number of SSE* or AVX-128 single precision FP packed uops executed. | |
| 10H | 80H | FP_COMP_OPS_EXE.SSE_SCALAR_DOUBLE | Counts number of SSE* or AVX-128 double precision FP scalar uops executed. | |
| 11H | 01H | SIMD_FP_256.PACKED_SINGLE | Counts 256-bit packed single-precision floating-point instructions. | |
| 11H | 02H | SIMD_FP_256.PACKED_DOUBLE | Counts 256-bit packed double-precision floating-point instructions. | |
| 14H | 01H | ARITH.FPU_DIV_ACTIVE | Cycles that the divider is active, includes INT and FP. Set 'edge =1, cmask=1' to count the number of divides. | |
| 24H | 01H | L2_RQSTS.DEMAND_DATA_RD_HIT | Demand Data Read requests that hit L2 cache | |
| 24H | 03H | L2_RQSTS.ALL_DEMAND_DATA_RD | Counts any demand and L1 HW prefetch data load requests to L2. | |
| 24H | 04H | L2_RQSTS.RFO_HITS | Counts the number of store RFO requests that hit the L2 cache. | |
| 24H | 08H | L2_RQSTS.RFO_MISS | Counts the number of store RFO requests that miss the L2 cache. | |
| 24H | 0CH | L2_RQSTS.ALL_RFO | Counts all L2 store RFO requests. | |
| 24H | 10H | L2_RQSTS.CODE_RD_HIT | Number of instruction fetches that hit the L2 cache. | |
| 24H | 20H | L2_RQSTS.CODE_RD_MISS | Number of instruction fetches that missed the L2 cache. | |
| 24H | 30H | L2_RQSTS.ALL_CODE_RD | Counts all L2 code requests. | |
| 24H | 40H | L2_RQSTS.PF_HIT | Counts all L2 HW prefetcher requests that hit L2. | |
| 24H | 80H | L2_RQSTS.PF_MISS | Counts all L2 HW prefetcher requests that missed L2. | |
| 24H | C0H | L2_RQSTS.ALL_PF | Counts all L2 HW prefetcher requests. | |
| 27H | 01H | L2_STORE_LOCK_RQSTS.MISS | RFOs that miss cache lines | |

## Table 19-7. Non-Architectural Performance Events In the Processor Core of 3rd Generation Intel® Core™ i7, i5, i3 Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 27H | 08H | L2_STORE_LOCK_RQSTS.HIT_M | RFOs that hit cache lines in M state | |
| 27H | 0FH | L2_STORE_LOCK_RQSTS.ALL | RFOs that access cache lines in any state | |
| 28H | 01H | L2_L1D_WB_RQSTS.MISS | Not rejected writebacks that missed LLC. | |
| 28H | 04H | L2_L1D_WB_RQSTS.HIT_E | Not rejected writebacks from L1D to L2 cache lines in E state. | |
| 28H | 08H | L2_L1D_WB_RQSTS.HIT_M | Not rejected writebacks from L1D to L2 cache lines in M state. | |
| 28H | 0FH | L2_L1D_WB_RQSTS.ALL | Not rejected writebacks from L1D to L2 cache lines in any state. | |
| 2EH | 4FH | LONGEST_LAT_CACHE.REFERENCE | This event counts requests originating from the core that reference a cache line in the last level cache. | see Table 19-1 |
| 2EH | 41H | LONGEST_LAT_CACHE.MISS | This event counts each cache miss condition for references to the last level cache. | see Table 19-1 |
| 3CH | 00H | CPU_CLK_UNHALTED.THREAD_P | Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling. | see Table 19-1 |
| 3CH | 01H | CPU_CLK_THREAD_UNHALTED.REF_XCLK | Increments at the frequency of XCLK (100 MHz) when not halted. | see Table 19-1 |
| 48H | 01H | L1D_PEND_MISS.PENDING | Increments the number of outstanding L1D misses every cycle. Set Cmaks = 1 and Edge =1 to count occurrences. | PMC2 only;<br>Set Cmask = 1 to count cycles. |
| 49H | 01H | DTLB_STORE_MISSES.MISS_CAUSES_A_WALK | Miss in all TLB levels causes an page walk of any page size (4K/2M/4M/1G). | |
| 49H | 02H | DTLB_STORE_MISSES.WALK_COMPLETED | Miss in all TLB levels causes a page walk that completes of any page size (4K/2M/4M/1G). | |
| 49H | 04H | DTLB_STORE_MISSES.WALK_DURATION | Cycles PMH is busy with this walk. | |
| 49H | 10H | DTLB_STORE_MISSES.STLB_HIT | Store operations that miss the first TLB level but hit the second and do not cause page walks | |
| 4CH | 01H | LOAD_HIT_PRE.SW_PF | Non-SW-prefetch load dispatches that hit fill buffer allocated for S/W prefetch. | |
| 4CH | 02H | LOAD_HIT_PRE.HW_PF | Non-SW-prefetch load dispatches that hit fill buffer allocated for H/W prefetch. | |
| 51H | 01H | L1D.REPLACEMENT | Counts the number of lines brought into the L1 data cache. | |
| 58H | 04H | MOVE_ELIMINATION.INT_NOT_ELIMINATED | Number of integer Move Elimination candidate uops that were not eliminated. | |
| 58H | 08H | MOVE_ELIMINATION.SIMD_NOT_ELIMINATED | Number of SIMD Move Elimination candidate uops that were not eliminated. | |
| 58H | 01H | MOVE_ELIMINATION.INT_ELIMINATED | Number of integer Move Elimination candidate uops that were eliminated. | |
| 58H | 02H | MOVE_ELIMINATION.SIMD_ELIMINATED | Number of SIMD Move Elimination candidate uops that were eliminated. | |

## Table 19-7. Non-Architectural Performance Events In the Processor Core of 3rd Generation Intel® Core™ i7, i5, i3 Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 5CH | 01H | CPL_CYCLES.RING0 | Unhalted core cycles when the thread is in ring 0. | Use Edge to count transition |
| 5CH | 02H | CPL_CYCLES.RING123 | Unhalted core cycles when the thread is not in ring 0. | |
| 5EH | 01H | RS_EVENTS.EMPTY_CYCLES | Cycles the RS is empty for the thread. | |
| 5FH | 04H | DTLB_LOAD_MISSES.STLB_HIT | Counts load operations that missed 1st level DTLB but hit the 2nd level. | |
| 60H | 01H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_DATA_RD | Offcore outstanding Demand Data Read transactions in SQ to uncore. Set Cmask=1 to count cycles. | |
| 60H | 02H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_CODE_RD | Offcore outstanding Demand Code Read transactions in SQ to uncore. Set Cmask=1 to count cycles. | |
| 60H | 04H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_RFO | Offcore outstanding RFO store transactions in SQ to uncore. Set Cmask=1 to count cycles. | |
| 60H | 08H | OFFCORE_REQUESTS_OUTSTANDING.ALL_DATA_RD | Offcore outstanding cacheable data read transactions in SQ to uncore. Set Cmask=1 to count cycles. | |
| 63H | 01H | LOCK_CYCLES.SPLIT_LOCK_UC_LOCK_DURATION | Cycles in which the L1D and L2 are locked, due to a UC lock or split lock. | |
| 63H | 02H | LOCK_CYCLES.CACHE_LOCK_DURATION | Cycles in which the L1D is locked. | |
| 79H | 02H | IDQ.EMPTY | Counts cycles the IDQ is empty. | |
| 79H | 04H | IDQ.MITE_UOPS | Increment each cycle # of uops delivered to IDQ from MITE path.<br>Set Cmask = 1 to count cycles. | Can combine Umask 04H and 20H |
| 79H | 08H | IDQ.DSB_UOPS | Increment each cycle. # of uops delivered to IDQ from DSB path.<br>Set Cmask = 1 to count cycles. | Can combine Umask 08H and 10H |
| 79H | 10H | IDQ.MS_DSB_UOPS | Increment each cycle # of uops delivered to IDQ when MS_busy by DSB. Set Cmask = 1 to count cycles. Add Edge=1 to count # of delivery. | Can combine Umask 04H, 08H |
| 79H | 20H | IDQ.MS_MITE_UOPS | Increment each cycle # of uops delivered to IDQ when MS_busy by MITE. Set Cmask = 1 to count cycles. | Can combine Umask 04H, 08H |
| 79H | 30H | IDQ.MS_UOPS | Increment each cycle # of uops delivered to IDQ from MS by either DSB or MITE. Set Cmask = 1 to count cycles. | Can combine Umask 04H, 08H |
| 79H | 18H | IDQ.ALL_DSB_CYCLES_ANY_UOPS | Counts cycles DSB is delivered at least one uops. Set Cmask = 1. | |
| 79H | 18H | IDQ.ALL_DSB_CYCLES_4_UOPS | Counts cycles DSB is delivered four uops. Set Cmask = 4. | |
| 79H | 24H | IDQ.ALL_MITE_CYCLES_ANY_UOPS | Counts cycles MITE is delivered at least one uops. Set Cmask = 1. | |
| 79H | 24H | IDQ.ALL_MITE_CYCLES_4_UOPS | Counts cycles MITE is delivered four uops. Set Cmask = 4. | |

## Table 19-7. Non-Architectural Performance Events In the Processor Core of 3rd Generation Intel® Core™ i7, i5, i3 Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 79H | 3CH | IDQ.MITE_ALL_UOPS | # of uops delivered to IDQ from any path. | |
| 80H | 04H | ICACHE.IFETCH_STALL | Cycles where a code-fetch stalled due to L1 instruction-cache miss or an iTLB miss | |
| 80H | 02H | ICACHE.MISSES | Number of Instruction Cache, Streaming Buffer and Victim Cache Misses. Includes UC accesses. | |
| 85H | 01H | ITLB_MISSES.MISS_CAUSES_A_WALK | Misses in all ITLB levels that cause page walks | |
| 85H | 02H | ITLB_MISSES.WALK_COMPLETED | Misses in all ITLB levels that cause completed page walks | |
| 85H | 04H | ITLB_MISSES.WALK_DURATION | Cycle PMH is busy with a walk. | |
| 85H | 10H | ITLB_MISSES.STLB_HIT | Number of cache load STLB hits. No page walk. | |
| 87H | 01H | ILD_STALL.LCP | Stalls caused by changing prefix length of the instruction. | |
| 87H | 04H | ILD_STALL.IQ_FULL | Stall cycles due to IQ is full. | |
| 88H | 01H | BR_INST_EXEC.COND | Qualify conditional near branch instructions executed, but not necessarily retired. | Must combine with umask 40H, 80H |
| 88H | 02H | BR_INST_EXEC.DIRECT_JMP | Qualify all unconditional near branch instructions excluding calls and indirect branches. | Must combine with umask 80H |
| 88H | 04H | BR_INST_EXEC.INDIRECT_JMP_NON_CALL_RET | Qualify executed indirect near branch instructions that are not calls nor returns. | Must combine with umask 80H |
| 88H | 08H | BR_INST_EXEC.RETURN_NEAR | Qualify indirect near branches that have a return mnemonic. | Must combine with umask 80H |
| 88H | 10H | BR_INST_EXEC.DIRECT_NEAR_CALL | Qualify unconditional near call branch instructions, excluding non call branch, executed. | Must combine with umask 80H |
| 88H | 20H | BR_INST_EXEC.INDIRECT_NEAR_CALL | Qualify indirect near calls, including both register and memory indirect, executed. | Must combine with umask 80H |
| 88H | 40H | BR_INST_EXEC.NONTAKEN | Qualify non-taken near branches executed. | Applicable to umask 01H only |
| 88H | 80H | BR_INST_EXEC.TAKEN | Qualify taken near branches executed. Must combine with 01H,02H, 04H, 08H, 10H, 20H. | |
| 88H | FFH | BR_INST_EXEC.ALL_BRANCHES | Counts all near executed branches (not necessarily retired). | |
| 89H | 01H | BR_MISP_EXEC.COND | Qualify conditional near branch instructions mispredicted. | Must combine with umask 40H, 80H |
| 89H | 04H | BR_MISP_EXEC.INDIRECT_JMP_NON_CALL_RET | Qualify mispredicted indirect near branch instructions that are not calls nor returns. | Must combine with umask 80H |
| 89H | 08H | BR_MISP_EXEC.RETURN_NEAR | Qualify mispredicted indirect near branches that have a return mnemonic. | Must combine with umask 80H |
| 89H | 10H | BR_MISP_EXEC.DIRECT_NEAR_CALL | Qualify mispredicted unconditional near call branch instructions, excluding non call branch, executed. | Must combine with umask 80H |
| 89H | 20H | BR_MISP_EXEC.INDIRECT_NEAR_CALL | Qualify mispredicted indirect near calls, including both register and memory indirect, executed. | Must combine with umask 80H |
| 89H | 40H | BR_MISP_EXEC.NONTAKEN | Qualify mispredicted non-taken near branches executed. | Applicable to umask 01H only |

## Table 19-7. Non-Architectural Performance Events In the Processor Core of 3rd Generation Intel® Core™ i7, i5, i3 Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 89H | 80H | BR_MISP_EXEC.TAKEN | Qualify mispredicted taken near branches executed. Must combine with 01H,02H, 04H, 08H, 10H, 20H. | |
| 89H | FFH | BR_MISP_EXEC.ALL_BRANCHES | Counts all near executed branches (not necessarily retired). | |
| 9CH | 01H | IDQ_UOPS_NOT_DELIVERED.CORE | Count number of non-delivered uops to RAT per thread. | Use Cmask to qualify uop b/w |
| A1H | 01H | UOPS_DISPATCHED_PORT.PORT_0 | Cycles which a Uop is dispatched on port 0. | |
| A1H | 02H | UOPS_DISPATCHED_PORT.PORT_1 | Cycles which a Uop is dispatched on port 1 | |
| A1H | 0CH | UOPS_DISPATCHED_PORT.PORT_2 | Cycles which a Uop is dispatched on port 2. | |
| A1H | 30H | UOPS_DISPATCHED_PORT.PORT_3 | Cycles which a Uop is dispatched on port 3. | |
| A1H | 40H | UOPS_DISPATCHED_PORT.PORT_4 | Cycles which a Uop is dispatched on port 4. | |
| A1H | 80H | UOPS_DISPATCHED_PORT.PORT_5 | Cycles which a Uop is dispatched on port 5. | |
| A2H | 01H | RESOURCE_STALLS.ANY | Cycles Allocation is stalled due to Resource Related reason. | |
| A2H | 04H | RESOURCE_STALLS.RS | Cycles stalled due to no eligible RS entry available. | |
| A2H | 08H | RESOURCE_STALLS.SB | Cycles stalled due to no store buffers available (not including draining form sync). | |
| A2H | 10H | RESOURCE_STALLS.ROB | Cycles stalled due to re-order buffer full. | |
| A3H | 01H | CYCLE_ACTIVITY.CYCLES_L2_PENDING | Cycles with pending L2 miss loads. Set AnyThread to count per core. | |
| A3H | 02H | CYCLE_ACTIVITY.CYCLES_LDM_PENDING | Cycles with pending memory loads. Set AnyThread to count per core. | PMC0-3 only. |
| A3H | 08H | CYCLE_ACTIVITY.CYCLES_L1D_PENDING | Cycles with pending L1 cache miss loads. Set AnyThread to count per core. | PMC2 only |
| A3H | 04H | CYCLE_ACTIVITY.CYCLES_NO_EXECUTE | Cycles of dispatch stalls. Set AnyThread to count per core. | |
| A8H | 01H | LSD.UOPS | Number of Uops delivered by the LSD. | |
| ABH | 01H | DSB2MITE_SWITCHES.COUNT | Number of DSB to MITE switches. | |
| ABH | 02H | DSB2MITE_SWITCHES.PENALTY_CYCLES | Cycles DSB to MITE switches caused delay. | |
| ACH | 08H | DSB_FILL.EXCEED_DSB_LINES | DSB Fill encountered > 3 DSB lines. | |
| AEH | 01H | ITLB.ITLB_FLUSH | Counts the number of ITLB flushes, includes 4k/2M/4M pages. | |
| B0H | 01H | OFFCORE_REQUESTS.DEMAND_DATA_RD | Demand data read requests sent to uncore. | |
| B0H | 02H | OFFCORE_REQUESTS.DEMAND_CODE_RD | Demand code read requests sent to uncore. | |
| B0H | 04H | OFFCORE_REQUESTS.DEMAND_RFO | Demand RFO read requests sent to uncore, including regular RFOs, locks, ItoM | |

### Table 19-7. Non-Architectural Performance Events In the Processor Core of 3rd Generation Intel® Core™ i7, i5, i3 Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| B0H | 08H | OFFCORE_REQUESTS.ALL_DATA_RD | Data read requests sent to uncore (demand and prefetch). | |
| B1H | 01H | UOPS_EXECUTED.THREAD | Counts total number of uops to be executed per-thread each cycle. Set Cmask = 1, INV =1 to count stall cycles. | |
| B1H | 02H | UOPS_EXECUTED.CORE | Counts total number of uops to be executed per-core each cycle. | Do not need to set ANY |
| B7H | 01H | OFFCORE_RESPONSE_0 | see Section 18.9.5, "Off-core Response Performance Monitoring". | Requires MSR 01A6H |
| BBH | 01H | OFFCORE_RESPONSE_1 | See Section 18.9.5, "Off-core Response Performance Monitoring". | Requires MSR 01A7H |
| BDH | 01H | TLB_FLUSH.DTLB_THREAD | DTLB flush attempts of the thread-specific entries. | |
| BDH | 20H | TLB_FLUSH.STLB_ANY | Count number of STLB flush attempts. | |
| C0H | 00H | INST_RETIRED.ANY_P | Number of instructions at retirement. | See Table 19-1 |
| C0H | 01H | INST_RETIRED.PREC_DIST | Precise instruction retired event with HW to reduce effect of PEBS shadow in IP distribution. | PMC1 only |
| C1H | 08H | OTHER_ASSISTS.AVX_STORE | Number of assists associated with 256-bit AVX store operations. | |
| C1H | 10H | OTHER_ASSISTS.AVX_TO_SSE | Number of transitions from AVX-256 to legacy SSE when penalty applicable. | |
| C1H | 20H | OTHER_ASSISTS.SSE_TO_AVX | Number of transitions from SSE to AVX-256 when penalty applicable. | |
| C1H | 80H | OTHER_ASSISTS.WB | Number of times microcode assist is invoked by hardware upon uop writeback | |
| C2H | 01H | UOPS_RETIRED.ALL | Counts the number of micro-ops retired, Use cmask=1 and invert to count active cycles or stalled cycles. | Supports PEBS, use Any=1 for core granular. |
| C2H | 02H | UOPS_RETIRED.RETIRE_SLOTS | Counts the number of retirement slots used each cycle. | Supports PEBS |
| C3H | 02H | MACHINE_CLEARS.MEMORY_ORDERING | Counts the number of machine clears due to memory order conflicts. | |
| C3H | 04H | MACHINE_CLEARS.SMC | Number of self-modifying-code machine clears detected. | |
| C3H | 20H | MACHINE_CLEARS.MASKMOV | Counts the number of executed AVX masked load operations that refer to an illegal address range with the mask bits set to 0. | |
| C4H | 00H | BR_INST_RETIRED.ALL_BRANCHES | Branch instructions at retirement. | See Table 19-1 |
| C4H | 01H | BR_INST_RETIRED.CONDITIONAL | Counts the number of conditional branch instructions retired. | Supports PEBS |
| C4H | 02H | BR_INST_RETIRED.NEAR_CALL | Direct and indirect near call instructions retired. | Supports PEBS |
| C4H | 04H | BR_INST_RETIRED.ALL_BRANCHES | Counts the number of branch instructions retired. | Supports PEBS |
| C4H | 08H | BR_INST_RETIRED.NEAR_RETURN | Counts the number of near return instructions retired. | Supports PEBS |

## Table 19-7. Non-Architectural Performance Events In the Processor Core of 3rd Generation Intel® Core™ i7, i5, i3 Processors (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| C4H | 10H | BR_INST_RETIRED.NOT_TAKEN | Counts the number of not taken branch instructions retired. | Supports PEBS |
| C4H | 20H | BR_INST_RETIRED.NEAR_TAKEN | Number of near taken branches retired. | Supports PEBS |
| C4H | 40H | BR_INST_RETIRED.FAR_BRANCH | Number of far branches retired. | Supports PEBS |
| C5H | 00H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted branch instructions at retirement. | See Table 19-1 |
| C5H | 01H | BR_MISP_RETIRED.CONDITIONAL | Mispredicted conditional branch instructions retired. | Supports PEBS |
| C5H | 04H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted macro branch instructions retired. | Supports PEBS |
| C5H | 20H | BR_MISP_RETIRED.NEAR_TAKEN | Mispredicted taken branch instructions retired. | Supports PEBS |
| CAH | 02H | FP_ASSIST.X87_OUTPUT | Number of X87 FP assists due to Output values. | Supports PEBS |
| CAH | 04H | FP_ASSIST.X87_INPUT | Number of X87 FP assists due to input values. | Supports PEBS |
| CAH | 08H | FP_ASSIST.SIMD_OUTPUT | Number of SIMD FP assists due to Output values. | Supports PEBS |
| CAH | 10H | FP_ASSIST.SIMD_INPUT | Number of SIMD FP assists due to input values. | |
| CAH | 1EH | FP_ASSIST.ANY | Cycles with any input/output SSE* or FP assists. | |
| CCH | 20H | ROB_MISC_EVENTS.LBR_INSERTS | Count cases of saving new LBR records by hardware. | |
| CDH | 01H | MEM_TRANS_RETIRED.LOAD_LATENCY | Randomly sampled loads whose latency is above a user defined threshold. A small fraction of the overall loads are sampled due to randomization. | Specify threshold in MSR 3F6H |
| CDH | 02H | MEM_TRANS_RETIRED.PRECISE_STORE | Sample stores and collect precise store operation via PEBS record. PMC3 only. | See Section 18.9.4.3 |
| D0H | 01H | MEM_UOPS_RETIRED.LOADS | Qualify retired memory uops that are loads. Combine with umask 10H, 20H, 40H, 80H. | Supports PEBS |
| D0H | 10H | MEM_UOPS_RETIRED.STLB_MISS | Qualify retired memory uops with STLB miss. Must combine with umask 01H, 02H, to produce counts. | Supports PEBS |
| D0H | 40H | MEM_UOPS_RETIRED.SPLIT | Qualify retired memory uops with line split. Must combine with umask 01H, 02H, to produce counts. | Supports PEBS |
| D0H | 80H | MEM_UOPS_RETIRED.ALL | Qualify any retired memory uops. Must combine with umask 01H, 02H, to produce counts. | Supports PEBS |
| D1H | 01H | MEM_LOAD_UOPS_RETIRED.L1_HIT | Retired load uops with L1 cache hits as data sources. | Supports PEBS |
| D1H | 02H | MEM_LOAD_UOPS_RETIRED.L2_HIT | Retired load uops with L2 cache hits as data sources. | Supports PEBS |
| D1H | 04H | MEM_LOAD_UOPS_RETIRED.LLC_HIT | Retired load uops whose data source was LLC hit with no snoop required. | Supports PEBS |
| D1H | 08H | MEM_LOAD_UOPS_RETIRED.L1_MISS | Retired load uops whose data source followed an L1 miss | Supports PEBS |
| D1H | 10H | MEM_LOAD_UOPS_RETIRED.L2_MISS | Retired load uops that missed L2, excluding unknown sources | Supports PEBS |
| D1H | 20H | MEM_LOAD_UOPS_RETIRED.LLC_MISS | Retired load uops whose data source is LLC miss | Supports PEBS |
| D1H | 40H | MEM_LOAD_UOPS_RETIRED.HIT_LFB | Retired load uops which data sources were load uops missed L1 but hit FB due to preceding miss to the same cache line with data not ready. | Supports PEBS |

**Table 19-7. Non-Architectural Performance Events In the Processor Core of 3rd Generation Intel® Core™ i7, i5, i3 Processors (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| D2H | 01H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_MISS | Retired load uops whose data source was an on-package core cache LLC hit and cross-core snoop missed. | Supports PEBS |
| D2H | 02H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_HIT | Retired load uops whose data source was an on-package LLC hit and cross-core snoop hits. | Supports PEBS |
| D2H | 04H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_HITM | Retired load uops whose data source was an on-package core cache with HitM responses. | Supports PEBS |
| D2H | 08H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_NONE | Retired load uops whose data source was LLC hit with no snoop required. | Supports PEBS |
| D3H | 01H | MEM_LOAD_UOPS_LLC_MISS_RETIRED.LOCAL_DRAM | Retired load uops whose data source was local memory (cross-socket snoop not needed or missed). | Supports PEBS. |
| E6H | 1FH | BACLEARS.ANY | Number of front end re-steers due to BPU misprediction. | |
| F0H | 01H | L2_TRANS.DEMAND_DATA_RD | Demand Data Read requests that access L2 cache. | |
| F0H | 02H | L2_TRANS.RFO | RFO requests that access L2 cache. | |
| F0H | 04H | L2_TRANS.CODE_RD | L2 cache accesses when fetching instructions. | |
| F0H | 08H | L2_TRANS.ALL_PF | Any MLC or LLC HW prefetch accessing L2, including rejects. | |
| F0H | 10H | L2_TRANS.L1D_WB | L1D writebacks that access L2 cache. | |
| F0H | 20H | L2_TRANS.L2_FILL | L2 fill requests that access L2 cache. | |
| F0H | 40H | L2_TRANS.L2_WB | L2 writebacks that access L2 cache. | |
| F0H | 80H | L2_TRANS.ALL_REQUESTS | Transactions accessing L2 pipe. | |
| F1H | 01H | L2_LINES_IN.I | L2 cache lines in I state filling L2. | Counting does not cover rejects. |
| F1H | 02H | L2_LINES_IN.S | L2 cache lines in S state filling L2. | Counting does not cover rejects. |
| F1H | 04H | L2_LINES_IN.E | L2 cache lines in E state filling L2. | Counting does not cover rejects. |
| F1H | 07H | L2_LINES_IN.ALL | L2 cache lines filling L2. | Counting does not cover rejects. |
| F2H | 01H | L2_LINES_OUT.DEMAND_CLEAN | Clean L2 cache lines evicted by demand. | |
| F2H | 02H | L2_LINES_OUT.DEMAND_DIRTY | Dirty L2 cache lines evicted by demand. | |
| F2H | 04H | L2_LINES_OUT.PF_CLEAN | Clean L2 cache lines evicted by the MLC prefetcher. | |
| F2H | 08H | L2_LINES_OUT.PF_DIRTY | Dirty L2 cache lines evicted by the MLC prefetcher. | |
| F2H | 0AH | L2_LINES_OUT.DIRTY_ALL | Dirty L2 cache lines filling the L2. | Counting does not cover rejects. |

### 19.4.1 Performance Monitoring Events in the Processor Core of Intel Xeon Processor E5 v2 Family and Intel Xeon Processor E7 v2 Family

Non-architectural performance monitoring events in the processor core that are applicable only to Intel Xeon processor E5 v2 family and Intel Xeon processor E7 v2 family based on the Ivy Bridge-E microarchitecture, with CPUID signature of DisplayFamily_DisplayModel 06_3EH, are listed in Table 19-8.

**Table 19-8. Non-Architectural Performance Events Applicable only to the Processor Core of Intel® Xeon® Processor E5 v2 Family and Intel® Xeon® Processor E7 v2 Family**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| D3H | 03H | MEM_LOAD_UOPS_LLC_MISS_RETIRED.LOCAL_DRAM | Retired load uops whose data sources was local DRAM (snoop not needed, Snoop Miss, or Snoop Hit data not forwarded). | Supports PEBS |
| D3H | 0CH | MEM_LOAD_UOPS_LLC_MISS_RETIRED.REMOTE_DRAM | Retired load uops whose data source was remote DRAM (snoop not needed, Snoop Miss, or Snoop Hit data not forwarded). | Supports PEBS |
| D3H | 10H | MEM_LOAD_UOPS_LLC_MISS_RETIRED.REMOTE_HITM | Retired load uops whose data sources was remote HITM. | Supports PEBS |
| D3H | 20H | MEM_LOAD_UOPS_LLC_MISS_RETIRED.REMOTE_FWD | Retired load uops whose data sources was forwards from a remote cache. | Supports PEBS |

## 19.5 PERFORMANCE MONITORING EVENTS FOR 2ND GENERATION INTEL® CORE™ I7-2XXX, INTEL® CORE™ I5-2XXX, INTEL® CORE™ I3-2XXX PROCESSOR SERIES

2nd generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx processor series, and Intel Xeon processor E3-1200 product family are based on the Intel microarchitecture code name Sandy Bridge. They support architectural performance-monitoring events listed in Table 19-1. Non-architectural performance-monitoring events in the processor core are listed in Table 19-9, Table 19-10, and Table 19-11. The events in Table 19-9 apply to processors with CPUID signature of DisplayFamily_DisplayModel encoding with the following values: 06_2AH and 06_2DH. The events in Table 19-10 apply to processors with CPUID signature 06_2AH. The events in Table 19-11 apply to processors with CPUID signature 06_2DH.

Additional informations on event specifics (e.g. derivative events using specific IA32_PERFEVTSELx modifiers, limitations, special notes and recommendations) can be found at http://software.intel.com/en-us/forums/software-tuning-performance-optimization-platform-monitoring.

**Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 03H | 01H | LD_BLOCKS.DATA_UNKNOWN | blocked loads due to store buffer blocks with unknown data. | |
| 03H | 02H | LD_BLOCKS.STORE_FORWARD | loads blocked by overlapping with store buffer that cannot be forwarded . | |
| 03H | 08H | LD_BLOCKS.NO_SR | # of Split loads blocked due to resource not available. | |
| 03H | 10H | LD_BLOCKS.ALL_BLOCK | Number of cases where any load is blocked but has no DCU miss. | |
| 05H | 01H | MISALIGN_MEM_REF.LOADS | Speculative cache-line split load uops dispatched to L1D. | |
| 05H | 02H | MISALIGN_MEM_REF.STORES | Speculative cache-line split Store-address uops dispatched to L1D. | |
| 07H | 01H | LD_BLOCKS_PARTIAL.ADDRESS_ALIAS | False dependencies in MOB due to partial compare on address. | |

**Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 07H | 08H | LD_BLOCKS_PARTIAL.ALL_STA_BLOCK | The number of times that load operations are temporarily blocked because of older stores, with addresses that are not yet known. A load operation may incur more than one block of this type. | |
| 08H | 01H | DTLB_LOAD_MISSES.MISS_CAUSES_A_WALK | Misses in all TLB levels that cause a page walk of any page size. | |
| 08H | 02H | DTLB_LOAD_MISSES.WALK_COMPLETED | Misses in all TLB levels that caused page walk completed of any size. | |
| 08H | 04H | DTLB_LOAD_MISSES.WALK_DURATION | Cycle PMH is busy with a walk. | |
| 08H | 10H | DTLB_LOAD_MISSES.STLB_HIT | Number of cache load STLB hits. No page walk. | |
| 0DH | 03H | INT_MISC.RECOVERY_CYCLES | Cycles waiting to recover after Machine Clears or JEClear. Set Cmask= 1. | Set Edge to count occurrences |
| 0DH | 40H | INT_MISC.RAT_STALL_CYCLES | Cycles RAT external stall is sent to IDQ for this thread. | |
| 0EH | 01H | UOPS_ISSUED.ANY | Increments each cycle the # of Uops issued by the RAT to RS.<br>Set Cmask = 1, Inv = 1, Any= 1to count stalled cycles of this core. | Set Cmask = 1, Inv = 1to count stalled cycles |
| 10H | 01H | FP_COMP_OPS_EXE.X87 | Counts number of X87 uops executed. | |
| 10H | 10H | FP_COMP_OPS_EXE.SSE_FP_PACKED_DOUBLE | Counts number of SSE* double precision FP packed uops executed. | |
| 10H | 20H | FP_COMP_OPS_EXE.SSE_FP_SCALAR_SINGLE | Counts number of SSE* single precision FP scalar uops executed. | |
| 10H | 40H | FP_COMP_OPS_EXE.SSE_PACKED SINGLE | Counts number of SSE* single precision FP packed uops executed. | |
| 10H | 80H | FP_COMP_OPS_EXE.SSE_SCALAR_DOUBLE | Counts number of SSE* double precision FP scalar uops executed. | |
| 11H | 01H | SIMD_FP_256.PACKED_SINGLE | Counts 256-bit packed single-precision floating-point instructions. | |
| 11H | 02H | SIMD_FP_256.PACKED_DOUBLE | Counts 256-bit packed double-precision floating-point instructions. | |
| 14H | 01H | ARITH.FPU_DIV_ACTIVE | Cycles that the divider is active, includes INT and FP. Set 'edge =1, cmask=1' to count the number of divides. | |
| 17H | 01H | INSTS_WRITTEN_TO_IQ.INSTS | Counts the number of instructions written into the IQ every cycle. | |
| 24H | 01H | L2_RQSTS.DEMAND_DATA_RD_HIT | Demand Data Read requests that hit L2 cache. | |
| 24H | 03H | L2_RQSTS.ALL_DEMAND_DATA_RD | Counts any demand and L1 HW prefetch data load requests to L2. | |
| 24H | 04H | L2_RQSTS.RFO_HITS | Counts the number of store RFO requests that hit the L2 cache. | |
| 24H | 08H | L2_RQSTS.RFO_MISS | Counts the number of store RFO requests that miss the L2 cache. | |
| 24H | 0CH | L2_RQSTS.ALL_RFO | Counts all L2 store RFO requests. | |

### Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 24H | 10H | L2_RQSTS.CODE_RD_HIT | Number of instruction fetches that hit the L2 cache. | |
| 24H | 20H | L2_RQSTS.CODE_RD_MISS | Number of instruction fetches that missed the L2 cache. | |
| 24H | 30H | L2_RQSTS.ALL_CODE_RD | Counts all L2 code requests. | |
| 24H | 40H | L2_RQSTS.PF_HIT | Requests from L2 Hardware prefetcher that hit L2. | |
| 24H | 80H | L2_RQSTS.PF_MISS | Requests from L2 Hardware prefetcher that missed L2. | |
| 24H | C0H | L2_RQSTS.ALL_PF | Any requests from L2 Hardware prefetchers. | |
| 27H | 01H | L2_STORE_LOCK_RQSTS.MISS | RFOs that miss cache lines. | |
| 27H | 04H | L2_STORE_LOCK_RQSTS.HIT_E | RFOs that hit cache lines in E state. | |
| 27H | 08H | L2_STORE_LOCK_RQSTS.HIT_M | RFOs that hit cache lines in M state. | |
| 27H | 0FH | L2_STORE_LOCK_RQSTS.ALL | RFOs that access cache lines in any state. | |
| 28H | 01H | L2_L1D_WB_RQSTS.MISS | Not rejected writebacks from L1D to L2 cache lines that missed L2. | |
| 28H | 02H | L2_L1D_WB_RQSTS.HIT_S | Not rejected writebacks from L1D to L2 cache lines in S state. | |
| 28H | 04H | L2_L1D_WB_RQSTS.HIT_E | Not rejected writebacks from L1D to L2 cache lines in E state. | |
| 28H | 08H | L2_L1D_WB_RQSTS.HIT_M | Not rejected writebacks from L1D to L2 cache lines in M state. | |
| 28H | 0FH | L2_L1D_WB_RQSTS.ALL | Not rejected writebacks from L1D to L2 cache. | |
| 2EH | 4FH | LONGEST_LAT_CACHE.REFERENCE | This event counts requests originating from the core that reference a cache line in the last level cache. | see Table 19-1 |
| 2EH | 41H | LONGEST_LAT_CACHE.MISS | This event counts each cache miss condition for references to the last level cache. | see Table 19-1 |
| 3CH | 00H | CPU_CLK_UNHALTED.THREAD_P | Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling. | see Table 19-1 |
| 3CH | 01H | CPU_CLK_THREAD_UNHALTED.REF_XCLK | Increments at the frequency of XCLK (100 MHz) when not halted. | see Table 19-1 |
| 48H | 01H | L1D_PEND_MISS.PENDING | Increments the number of outstanding L1D misses every cycle. Set Cmaks = 1 and Edge =1 to count occurrences. | PMC2 only;<br>Set Cmask = 1 to count cycles. |
| 49H | 01H | DTLB_STORE_MISSES.MISS_CAUSES_A_WALK | Miss in all TLB levels causes an page walk of any page size (4K/2M/4M/1G). | |
| 49H | 02H | DTLB_STORE_MISSES.WALK_COMPLETED | Miss in all TLB levels causes a page walk that completes of any page size (4K/2M/4M/1G). | |
| 49H | 04H | DTLB_STORE_MISSES.WALK_DURATION | Cycles PMH is busy with this walk. | |

### Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 49H | 10H | DTLB_STORE_MISSES.STLB_HIT | Store operations that miss the first TLB level but hit the second and do not cause page walks. | |
| 4CH | 01H | LOAD_HIT_PRE.SW_PF | Not SW-prefetch load dispatches that hit fill buffer allocated for S/W prefetch. | |
| 4CH | 02H | LOAD_HIT_PRE.HW_PF | Not SW-prefetch load dispatches that hit fill buffer allocated for H/W prefetch. | |
| 4EH | 02H | HW_PRE_REQ.DL1_MISS | Hardware Prefetch requests that miss the L1D cache. A request is being counted each time it access the cache & miss it, including if a block is applicable or if hit the Fill Buffer for example. | This accounts for both L1 streamer and IP-based (IPP) HW prefetchers. |
| 51H | 01H | L1D.REPLACEMENT | Counts the number of lines brought into the L1 data cache. | |
| 51H | 02H | L1D.ALLOCATED_IN_M | Counts the number of allocations of modified L1D cache lines. | |
| 51H | 04H | L1D.EVICTION | Counts the number of modified lines evicted from the L1 data cache due to replacement. | |
| 51H | 08H | L1D.ALL_M_REPLACEMENT | Cache lines in M state evicted out of L1D due to Snoop HitM or dirty line replacement. | |
| 59H | 20H | PARTIAL_RAT_STALLS.FLAGS_MERGE_UOP | Increments the number of flags-merge uops in flight each cycle.<br>Set Cmask = 1 to count cycles. | |
| 59H | 40H | PARTIAL_RAT_STALLS.SLOW_LEA_WINDOW | Cycles with at least one slow LEA uop allocated. | |
| 59H | 80H | PARTIAL_RAT_STALLS.MUL_SINGLE_UOP | Number of Multiply packed/scalar single precision uops allocated. | |
| 5BH | 0CH | RESOURCE_STALLS2.ALL_FL_EMPTY | Cycles stalled due to free list empty. | PMC0-3 only regardless HTT |
| 5BH | 0FH | RESOURCE_STALLS2.ALL_PRF_CONTROL | Cycles stalled due to control structures full for physical registers. | |
| 5BH | 40H | RESOURCE_STALLS2.BOB_FULL | Cycles Allocator is stalled due Branch Order Buffer. | |
| 5BH | 4FH | RESOURCE_STALLS2.OOO_RSRC | Cycles stalled due to out of order resources full. | |
| 5CH | 01H | CPL_CYCLES.RING0 | Unhalted core cycles when the thread is in ring 0. | Use Edge to count transition |
| 5CH | 02H | CPL_CYCLES.RING123 | Unhalted core cycles when the thread is not in ring 0. | |
| 5EH | 01H | RS_EVENTS.EMPTY_CYCLES | Cycles the RS is empty for the thread. | |
| 60H | 01H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_DATA_RD | Offcore outstanding Demand Data Read transactions in SQ to uncore. Set Cmask=1 to count cycles. | |
| 60H | 04H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND_RFO | Offcore outstanding RFO store transactions in SQ to uncore. Set Cmask=1 to count cycles. | |
| 60H | 08H | OFFCORE_REQUESTS_OUTSTANDING.ALL_DATA_RD | Offcore outstanding cacheable data read transactions in SQ to uncore. Set Cmask=1 to count cycles. | |

**Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 63H | 01H | LOCK_CYCLES.SPLIT_LOCK_UC_LOCK_DURATION | Cycles in which the L1D and L2 are locked, due to a UC lock or split lock. | |
| 63H | 02H | LOCK_CYCLES.CACHE_LOCK_DURATION | Cycles in which the L1D is locked. | |
| 79H | 02H | IDQ.EMPTY | Counts cycles the IDQ is empty. | |
| 79H | 04H | IDQ.MITE_UOPS | Increment each cycle # of uops delivered to IDQ from MITE path.<br>Set Cmask = 1 to count cycles. | Can combine Umask 04H and 20H |
| 79H | 08H | IDQ.DSB_UOPS | Increment each cycle. # of uops delivered to IDQ from DSB path.<br>Set Cmask = 1 to count cycles. | Can combine Umask 08H and 10H |
| 79H | 10H | IDQ.MS_DSB_UOPS | Increment each cycle # of uops delivered to IDQ when MS busy by DSB. Set Cmask = 1 to count cycles MS is busy. Set Cmask=1 and Edge =1 to count MS activations. | Can combine Umask 08H and 10H |
| 79H | 20H | IDQ.MS_MITE_UOPS | Increment each cycle # of uops delivered to IDQ when MS is busy by MITE. Set Cmask = 1 to count cycles. | Can combine Umask 04H and 20H |
| 79H | 30H | IDQ.MS_UOPS | Increment each cycle # of uops delivered to IDQ from MS by either DSB or MITE. Set Cmask = 1 to count cycles. | Can combine Umask 04H, 08H and 30H |
| 80H | 02H | ICACHE.MISSES | Number of Instruction Cache, Streaming Buffer and Victim Cache Misses. Includes UC accesses. | |
| 85H | 01H | ITLB_MISSES.MISS_CAUSES_A_WALK | Misses in all ITLB levels that cause page walks. | |
| 85H | 02H | ITLB_MISSES.WALK_COMPLETED | Misses in all ITLB levels that cause completed page walks. | |
| 85H | 04H | ITLB_MISSES.WALK_DURATION | Cycle PMH is busy with a walk. | |
| 85H | 10H | ITLB_MISSES.STLB_HIT | Number of cache load STLB hits. No page walk. | |
| 87H | 01H | ILD_STALL.LCP | Stalls caused by changing prefix length of the instruction. | |
| 87H | 04H | ILD_STALL.IQ_FULL | Stall cycles due to IQ is full. | |
| 88H | 41H | BR_INST_EXEC.NONTAKEN_CONDITIONAL | Not-taken macro conditional branches | |
| 88H | 81H | BR_INST_EXEC.TAKEN_CONDITIONAL | Taken speculative and retired conditional branches | |
| 88H | 82H | BR_INST_EXEC.TAKEN_DIRECT_JUMP | Taken speculative and retired conditional branches excluding calls and indirects | |
| 88H | 84H | BR_INST_EXEC.TAKEN_INDIRECT_JUMP_NON_CALL_RET | Taken speculative and retired indirect branches excluding calls and returns | |
| 88H | 88H | BR_INST_EXEC.TAKEN_INDIRECT_NEAR_RETURN | Taken speculative and retired indirect branches that are returns | |
| 88H | 90H | BR_INST_EXEC.TAKEN_DIRECT_NEAR_CALL | Taken speculative and retired direct near calls | |

### Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 88H | A0H | BR_INST_EXEC.TAKEN_INDIRECT_NEAR_CALL | Taken speculative and retired indirect near calls | |
| 88H | C1H | BR_INST_EXEC.ALL_CONDITIONAL | Speculative and retired conditional branches | |
| 88H | C2H | BR_INST_EXEC.ALL_DIRECT_JUMP | Speculative and retired conditional branches excluding calls and indirects | |
| 88H | C4H | BR_INST_EXEC.ALL_INDIRECT_JUMP_NON_CALL_RET | Speculative and retired indirect branches excluding calls and returns | |
| 88H | C8H | BR_INST_EXEC.ALL_INDIRECT_NEAR_RETURN | Speculative and retired indirect branches that are returns | |
| 88H | D0H | BR_INST_EXEC.ALL_NEAR_CALL | Speculative and retired direct near calls | |
| 88H | FFH | BR_INST_EXEC.ALL_BRANCHES | Speculative and retired branches | |
| 89H | 41H | BR_MISP_EXEC.NONTAKEN_CONDITIONAL | Not-taken mispredicted macro conditional branches | |
| 89H | 81H | BR_MISP_EXEC.TAKEN_CONDITIONAL | Taken speculative and retired mispredicted conditional branches | |
| 89H | 84H | BR_MISP_EXEC.TAKEN_INDIRECT_JUMP_NON_CALL_RET | Taken speculative and retired mispredicted indirect branches excluding calls and returns | |
| 89H | 88H | BR_MISP_EXEC.TAKEN_RETURN_NEAR | Taken speculative and retired mispredicted indirect branches that are returns | |
| 89H | 90H | BR_MISP_EXEC.TAKEN_DIRECT_NEAR_CALL | Taken speculative and retired mispredicted direct near calls | |
| 89H | A0H | BR_MISP_EXEC.TAKEN_INDIRECT_NEAR_CALL | Taken speculative and retired mispredicted indirect near calls | |
| 89H | C1H | BR_MISP_EXEC.ALL_CONDITIONAL | Speculative and retired mispredicted conditional branches | |
| 89H | C4H | BR_MISP_EXEC.ALL_INDIRECT_JUMP_NON_CALL_RET | Speculative and retired mispredicted indirect branches excluding calls and returns | |
| 89H | D0H | BR_MISP_EXEC.ALL_NEAR_CALL | Speculative and retired mispredicted direct near calls | |
| 89H | FFH | BR_MISP_EXEC.ALL_BRANCHES | Speculative and retired mispredicted branches | |
| 9CH | 01H | IDQ_UOPS_NOT_DELIVERED.CORE | Count number of non-delivered uops to RAT per thread. | Use Cmask to qualify uop b/w |
| A1H | 01H | UOPS_DISPATCHED_PORT.PORT_0 | Cycles which a Uop is dispatched on port 0. | |
| A1H | 02H | UOPS_DISPATCHED_PORT.PORT_1 | Cycles which a Uop is dispatched on port 1. | |
| A1H | 0CH | UOPS_DISPATCHED_PORT.PORT_2 | Cycles which a Uop is dispatched on port 2. | |
| A1H | 30H | UOPS_DISPATCHED_PORT.PORT_3 | Cycles which a Uop is dispatched on port 3. | |
| A1H | 40H | UOPS_DISPATCHED_PORT.PORT_4 | Cycles which a Uop is dispatched on port 4. | |

**Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| A1H | 80H | UOPS_DISPATCHED_PORT.PORT_5 | Cycles which a Uop is dispatched on port 5. | |
| A2H | 01H | RESOURCE_STALLS.ANY | Cycles Allocation is stalled due to Resource Related reason. | |
| A2H | 02H | RESOURCE_STALLS.LB | Counts the cycles of stall due to lack of load buffers. | |
| A2H | 04H | RESOURCE_STALLS.RS | Cycles stalled due to no eligible RS entry available. | |
| A2H | 08H | RESOURCE_STALLS.SB | Cycles stalled due to no store buffers available. (not including draining form sync). | |
| A2H | 10H | RESOURCE_STALLS.ROB | Cycles stalled due to re-order buffer full. | |
| A2H | 20H | RESOURCE_STALLS.FCSW | Cycles stalled due to writing the FPU control word. | |
| A3H | 02H | CYCLE_ACTIVITY.CYCLES_L1D_PENDING | Cycles with pending L1 cache miss loads.Set AnyThread to count per core. | PMC2 only |
| A3H | 01H | CYCLE_ACTIVITY.CYCLES_L2_PENDING | Cycles with pending L2 miss loads. Set AnyThread to count per core. | |
| A3H | 04H | CYCLE_ACTIVITY.CYCLES_NO_DISPATCH | Cycles of dispatch stalls. Set AnyThread to count per core. | PMC0-3 only |
| A8H | 01H | LSD.UOPS | Number of Uops delivered by the LSD. | |
| ABH | 01H | DSB2MITE_SWITCHES.COUNT | Number of DSB to MITE switches. | |
| ABH | 02H | DSB2MITE_SWITCHES.PENALTY_CYCLES | Cycles DSB to MITE switches caused delay. | |
| ACH | 02H | DSB_FILL.OTHER_CANCEL | Cases of cancelling valid DSB fill not because of exceeding way limit. | |
| ACH | 08H | DSB_FILL.EXCEED_DSB_LINES | DSB Fill encountered > 3 DSB lines. | |
| AEH | 01H | ITLB.ITLB_FLUSH | Counts the number of ITLB flushes, includes 4k/2M/4M pages. | |
| B0H | 01H | OFFCORE_REQUESTS.DEMAND_DATA_RD | Demand data read requests sent to uncore. | |
| B0H | 04H | OFFCORE_REQUESTS.DEMAND_RFO | Demand RFO read requests sent to uncore, including regular RFOs, locks, ItoM. | |
| B0H | 08H | OFFCORE_REQUESTS.ALL_DATA_RD | Data read requests sent to uncore (demand and prefetch). | |
| B1H | 01H | UOPS_DISPATCHED.THREAD | Counts total number of uops to be dispatched per-thread each cycle. Set Cmask = 1, INV =1 to count stall cycles. | PMC0-3 only regardless HTT |
| B1H | 02H | UOPS_DISPATCHED.CORE | Counts total number of uops to be dispatched per-core each cycle. | Do not need to set ANY |
| B2H | 01H | OFFCORE_REQUESTS_BUFFER.SQ_FULL | Offcore requests buffer cannot take more entries for this thread core. | |
| B6H | 01H | AGU_BYPASS_CANCEL.COUNT | Counts executed load operations with all the following traits: 1. addressing of the format [base + offset], 2. the offset is between 1 and 2047, 3. the address specified in the base register is in one page and the address [base+offset] is in another page. | |
| B7H | 01H | OFF_CORE_RESPONSE_0 | see Section 18.9.5, "Off-core Response Performance Monitoring". | Requires MSR 01A6H |

### Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| BBH | 01H | OFF_CORE_RESPONSE_1 | See Section 18.9.5, "Off-core Response Performance Monitoring". | Requires MSR 01A7H |
| BDH | 01H | TLB_FLUSH.DTLB_THREAD | DTLB flush attempts of the thread-specific entries. | |
| BDH | 20H | TLB_FLUSH.STLB_ANY | Count number of STLB flush attempts. | |
| BFH | 05H | L1D_BLOCKS.BANK_CONFLICT_CYCLES | Cycles when dispatched loads are cancelled due to L1D bank conflicts with other load ports. | cmask=1 |
| C0H | 00H | INST_RETIRED.ANY_P | Number of instructions at retirement. | See Table 19-1 |
| C0H | 01H | INST_RETIRED.PREC_DIST | Precise instruction retired event with HW to reduce effect of PEBS shadow in IP distribution. | PMC1 only; Must quiesce other PMCs. |
| C1H | 02H | OTHER_ASSISTS.ITLB_MISS_RETIRED | Instructions that experienced an ITLB miss. | |
| C1H | 08H | OTHER_ASSISTS.AVX_STORE | Number of assists associated with 256-bit AVX store operations. | |
| C1H | 10H | OTHER_ASSISTS.AVX_TO_SSE | Number of transitions from AVX-256 to legacy SSE when penalty applicable. | |
| C1H | 20H | OTHER_ASSISTS.SSE_TO_AVX | Number of transitions from SSE to AVX-256 when penalty applicable. | |
| C2H | 01H | UOPS_RETIRED.ALL | Counts the number of micro-ops retired, Use cmask=1 and invert to count active cycles or stalled cycles. | Supports PEBS |
| C2H | 02H | UOPS_RETIRED.RETIRE_SLOTS | Counts the number of retirement slots used each cycle. | Supports PEBS |
| C3H | 02H | MACHINE_CLEARS.MEMORY_ORDERING | Counts the number of machine clears due to memory order conflicts. | |
| C3H | 04H | MACHINE_CLEARS.SMC | Counts the number of times that a program writes to a code section. | |
| C3H | 20H | MACHINE_CLEARS.MASKMOV | Counts the number of executed AVX masked load operations that refer to an illegal address range with the mask bits set to 0. | |
| C4H | 00H | BR_INST_RETIRED.ALL_BRANCHES | Branch instructions at retirement. | See Table 19-1 |
| C4H | 01H | BR_INST_RETIRED.CONDITIONAL | Counts the number of conditional branch instructions retired. | Supports PEBS |
| C4H | 02H | BR_INST_RETIRED.NEAR_CALL | Direct and indirect near call instructions retired. | Supports PEBS |
| C4H | 04H | BR_INST_RETIRED.ALL_BRANCHES | Counts the number of branch instructions retired. | Supports PEBS |
| C4H | 08H | BR_INST_RETIRED.NEAR_RETURN | Counts the number of near return instructions retired. | Supports PEBS |
| C4H | 10H | BR_INST_RETIRED.NOT_TAKEN | Counts the number of not taken branch instructions retired. | |
| C4H | 20H | BR_INST_RETIRED.NEAR_TAKEN | Number of near taken branches retired. | Supports PEBS |
| C4H | 40H | BR_INST_RETIRED.FAR_BRANCH | Number of far branches retired. | |

### Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| C5H | 00H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted branch instructions at retirement. | See Table 19-1 |
| C5H | 01H | BR_MISP_RETIRED.CONDITIONAL | Mispredicted conditional branch instructions retired. | Supports PEBS |
| C5H | 02H | BR_MISP_RETIRED.NEAR_CALL | Direct and indirect mispredicted near call instructions retired. | Supports PEBS |
| C5H | 04H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted macro branch instructions retired. | Supports PEBS |
| C5H | 10H | BR_MISP_RETIRED.NOT_TAKEN | Mispredicted not taken branch instructions retired. | Supports PEBS |
| C5H | 20H | BR_MISP_RETIRED.TAKEN | Mispredicted taken branch instructions retired. | Supports PEBS |
| CAH | 02H | FP_ASSIST.X87_OUTPUT | Number of X87 assists due to output value. | |
| CAH | 04H | FP_ASSIST.X87_INPUT | Number of X87 assists due to input value. | |
| CAH | 08H | FP_ASSIST.SIMD_OUTPUT | Number of SIMD FP assists due to output values. | |
| CAH | 10H | FP_ASSIST.SIMD_INPUT | Number of SIMD FP assists due to input values. | |
| CAH | 1EH | FP_ASSIST.ANY | Cycles with any input/output SSE* or FP assists. | |
| CCH | 20H | ROB_MISC_EVENTS.LBR_INSERTS | Count cases of saving new LBR records by hardware. | |
| CDH | 01H | MEM_TRANS_RETIRED.LOAD_LATENCY | Randomly sampled loads whose latency is above a user defined threshold. A small fraction of the overall loads are sampled due to randomization. PMC3 only. | Specify threshold in MSR 3F6H |
| CDH | 02H | MEM_TRANS_RETIRED.PRECISE_STORE | Sample stores and collect precise store operation via PEBS record. PMC3 only. | See Section 18.9.4.3 |
| D0H | 11H | MEM_UOP_RETIRED.STLB_MISS_LOADS | Load uops with true STLB miss retired to architectural path. | Supports PEBS. PMC0-3 only regardless HTT. |
| D0H | 12H | MEM_UOP_RETIRED.STLB_MISS_STORES | Store uops with true STLB miss retired to architectural path. | Supports PEBS. PMC0-3 only regardless HTT. |
| D0H | 21H | MEM_UOP_RETIRED.LOCK_LOADS | Load uops with lock access retired to architectural path. | Supports PEBS. PMC0-3 only regardless HTT. |
| D0H | 22H | MEM_UOP_RETIRED.LOCK_STORES | Store uops with lock access retired to architectural path. | Supports PEBS. PMC0-3 only regardless HTT. |
| D0H | 41H | MEM_UOP_RETIRED.SPLIT_LOADS | Load uops with cacheline split retired to architectural path. | Supports PEBS. PMC0-3 only regardless HTT. |
| D0H | 42H | MEM_UOP_RETIRED.SPLIT_STORES | Store uops with cacheline split retired to architectural path. | Supports PEBS. PMC0-3 only regardless HTT. |
| D0H | 81H | MEM_UOP_RETIRED.ALL_LOADS | ALL Load uops retired to architectural path. | Supports PEBS. PMC0-3 only regardless HTT. |
| D0H | 82H | MEM_UOP_RETIRED.ALL_STORES | ALL Store uops retired to architectural path. | Supports PEBS. PMC0-3 only regardless HTT. |
| D0H | 80H | MEM_UOP_RETIRED.ALL | Qualify any retired memory uops. Must combine with umask 01H, 02H, to produce counts. | |
| D1H | 01H | MEM_LOAD_UOPS_RETIRED.L1_HIT | Retired load uops with L1 cache hits as data sources. | Supports PEBS. PMC0-3 only regardless HTT |

### Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| D1H | 02H | MEM_LOAD_UOPS_RETIRED.L2_HIT | Retired load uops with L2 cache hits as data sources. | Supports PEBS |
| D1H | 04H | MEM_LOAD_UOPS_RETIRED.LLC_HIT | Retired load uops which data sources were data hits in LLC without snoops required. | Supports PEBS |
| D1H | 20H | MEM_LOAD_UOPS_RETIRED.LLC_MISS | Retired load uops which data sources were data missed LLC (excluding unknown data source). | |
| D1H | 40H | MEM_LOAD_UOPS_RETIRED.HIT_LFB | Retired load uops which data sources were load uops missed L1 but hit FB due to preceding miss to the same cache line with data not ready. | Supports PEBS |
| D2H | 01H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_MISS | Retired load uops whose data source was an on-package core cache LLC hit and cross-core snoop missed. | Supports PEBS |
| D2H | 02H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_HIT | Retired load uops whose data source was an on-package LLC hit and cross-core snoop hits. | Supports PEBS |
| D2H | 04H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_HITM | Retired load uops whose data source was an on-package core cache with HitM responses. | Supports PEBS |
| D2H | 08H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_NONE | Retired load uops whose data source was LLC hit with no snoop required. | Supports PEBS |
| E6H | 01H | BACLEARS.ANY | Counts the number of times the front end is re-steered, mainly when the BPU cannot provide a correct prediction and this is corrected by other branch handling mechanisms at the front end. | |
| F0H | 01H | L2_TRANS.DEMAND_DATA_RD | Demand Data Read requests that access L2 cache. | |
| F0H | 02H | L2_TRANS.RFO | RFO requests that access L2 cache. | |
| F0H | 04H | L2_TRANS.CODE_RD | L2 cache accesses when fetching instructions. | |
| F0H | 08H | L2_TRANS.ALL_PF | L2 or LLC HW prefetches that access L2 cache. | Including rejects |
| F0H | 10H | L2_TRANS.L1D_WB | L1D writebacks that access L2 cache. | |
| F0H | 20H | L2_TRANS.L2_FILL | L2 fill requests that access L2 cache. | |
| F0H | 40H | L2_TRANS.L2_WB | L2 writebacks that access L2 cache. | |
| F0H | 80H | L2_TRANS.ALL_REQUESTS | Transactions accessing L2 pipe. | |
| F1H | 01H | L2_LINES_IN.I | L2 cache lines in I state filling L2. | Counting does not cover rejects. |
| F1H | 02H | L2_LINES_IN.S | L2 cache lines in S state filling L2. | Counting does not cover rejects. |
| F1H | 04H | L2_LINES_IN.E | L2 cache lines in E state filling L2. | Counting does not cover rejects. |
| F1H | 07H | L2_LINES_IN.ALL | L2 cache lines filling L2. | Counting does not cover rejects. |
| F2H | 01H | L2_LINES_OUT.DEMAND_CLEAN | Clean L2 cache lines evicted by demand. | |
| F2H | 02H | L2_LINES_OUT.DEMAND_DIRTY | Dirty L2 cache lines evicted by demand. | |
| F2H | 04H | L2_LINES_OUT.PF_CLEAN | Clean L2 cache lines evicted by L2 prefetch. | |
| F2H | 08H | L2_LINES_OUT.PF_DIRTY | Dirty L2 cache lines evicted by L2 prefetch. | |

### Table 19-9. Non-Architectural Performance Events In the Processor Core Common to 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series and Intel® Xeon® Processors E3 and E5 Family

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| F2H | 0AH | L2_LINES_OUT.DIRTY_ALL | Dirty L2 cache lines filling the L2. | Counting does not cover rejects. |
| F4H | 10H | SQ_MISC.SPLIT_LOCK | Split locks in SQ. | |

Non-architecture performance monitoring events in the processor core that are applicable only to Intel processor with CPUID signature of DisplayFamily_DisplayModel 06_2AH are listed in Table 19-10.

### Table 19-10. Non-Architectural Performance Events applicable only to the Processor core for 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| D2H | 01H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_MISS | Retired load uops which data sources were LLC hit and cross-core snoop missed in on-pkg core cache. | Supports PEBS. PMC0-3 only regardless HTT |
| D2H | 02H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_HIT | Retired load uops which data sources were LLC and cross-core snoop hits in on-pkg core cache. | |
| D2H | 04H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_HITM | Retired load uops which data sources were HitM responses from shared LLC. | |
| D2H | 08H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_NONE | Retired load uops which data sources were hits in LLC without snoops required. | |
| D4H | 02H | MEM_LOAD_UOPS_MISC_RETIRED.LLC_MISS | Retired load uops with unknown information as data source in cache serviced the load. | Supports PEBS. PMC0-3 only regardless HTT |
| B7H/BBH | 01H | OFF_CORE_RESPONSE_N | Sub-events of OFF_CORE_RESPONSE_N (suffix N = 0, 1) programmed using MSR 01A6H/01A7H with values shown in the comment column. | |
| | | OFFCORE_RESPONSE.ALL_CODE_RD.LLC_HIT_N | | 10003C0244H |
| | | OFFCORE_RESPONSE.ALL_CODE_RD.LLC_HIT.NO_SNOOP_NEEDED_N | | 1003C0244H |
| | | OFFCORE_RESPONSE.ALL_CODE_RD.LLC_HIT.SNOOP_MISS_N | | 2003C0244H |
| | | OFFCORE_RESPONSE.ALL_CODE_RD.LLC_HIT.MISS_DRAM_N | | 300400244H |
| | | OFFCORE_RESPONSE.ALL_DATA_RD.LLC_HIT.ANY_RESPONSE_N | | 3F803C0091H |
| | | OFFCORE_RESPONSE.ALL_DATA_RD.LLC_MISS.DRAM_N | | 300400091H |
| | | OFFCORE_RESPONSE.ALL_PF_CODE_RD.LLC_HIT.ANY_RESPONSE_N | | 3F803C0240H |
| | | OFFCORE_RESPONSE.ALL_PF_CODE_RD.LLC_HIT.HIT_OTHER_CORE_NO_FWD_N | | 4003C0240H |
| | | OFFCORE_RESPONSE.ALL_PF_CODE_RD.LLC_HIT.HITM_OTHER_CORE_N | | 10003C0240H |

Non-architecture performance monitoring events in the processor core that are applicable only to Intel Xeon processor E5 family (and Intel Core i7-3930 processor) based on Intel microarchitecture code name Sandy Bridge, with CPUID signature of DisplayFamily_DisplayModel 06_2DH, are listed in Table 19-11.

**Table 19-11. Non-Architectural Performance Events Applicable only to the Processor Core of Intel® Xeon® Processor E5 Family**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| CDH | 01H | MEM_TRANS_RETIRED.LOAD_LATENCY | Additional Configuration: Disable BL bypass and direct2core, and if the memory is remotely homed. The count is not reliable If the memory is locally homed. | |
| D1H | 04H | MEM_LOAD_UOPS_RETIRED.LLC_HIT | Additional Configuration: Disable BL bypass. Supports PEBS. | |
| D1H | 20H | MEM_LOAD_UOPS_RETIRED.LLC_MISS | Additional Configuration: Disable BL bypass and direct2core. Supports PEBS. | |
| D2H | 01H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_MISS | Additional Configuration: Disable bypass. Supports PEBS. | |
| D2H | 02H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_HIT | Additional Configuration: Disable bypass. Supports PEBS. | |
| D2H | 04H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_HITM | Additional Configuration: Disable bypass. Supports PEBS. | |
| D2H | 08H | MEM_LOAD_UOPS_LLC_HIT_RETIRED.XSNP_NONE | Additional Configuration: Disable bypass. Supports PEBS. | |
| D3H | 01H | MEM_LOAD_UOPS_LLC_MISS_RETIRED.LOCAL_DRAM | Retired load uops which data sources were data missed LLC but serviced by local DRAM. Supports PEBS. | Disable BL bypass and direct2core (see MSR 3C9H) |
| D3H | 04H | MEM_LOAD_UOPS_LLC_MISS_RETIRED.REMOTE_DRAM | Retired load uops which data sources were data missed LLC but serviced by remote DRAM. Supports PEBS. | Disable BL bypass and direct2core (see MSR 3C9H) |
| B7H/BBH | 01H | OFF_CORE_RESPONSE_N | Sub-events of OFF_CORE_RESPONSE_N (suffix N = 0, 1) programmed using MSR 01A6H/01A7H with values shown in the comment column. | |
| | | OFFCORE_RESPONSE.DEMAND_CODE_RD.LLC_MISS.ANY_RESPONSE_N | | 3FFFC00004H |

Non-architectural Performance monitoring events that are located in the uncore sub-system are implementation specific between different platforms using processors based on Intel microarchitecture code name Sandy Bridge. Processors with CPUID signature of DisplayFamily_DisplayModel 06_2AH support performance events listed in Table 19-12.

### Table 19-12. Non-Architectural Performance Events In the Processor Uncore for 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series

| Event Num.[1] | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 22H | 01H | UNC_CBO_XSNP_RESPONSE.MISS | A snoop misses in some processor core. | Must combine with one of the umask values of 20H, 40H, 80H |
| 22H | 02H | UNC_CBO_XSNP_RESPONSE.INVAL | A snoop invalidates a non-modified line in some processor core. | |
| 22H | 04H | UNC_CBO_XSNP_RESPONSE.HIT | A snoop hits a non-modified line in some processor core. | |
| 22H | 08H | UNC_CBO_XSNP_RESPONSE.HITM | A snoop hits a modified line in some processor core. | |
| 22H | 10H | UNC_CBO_XSNP_RESPONSE.INVAL_M | A snoop invalidates a modified line in some processor core. | |
| 22H | 20H | UNC_CBO_XSNP_RESPONSE.EXTERNAL_FILTER | Filter on cross-core snoops initiated by this Cbox due to external snoop request. | Must combine with at least one of 01H, 02H, 04H, 08H, 10H |
| 22H | 40H | UNC_CBO_XSNP_RESPONSE.XCORE_FILTER | Filter on cross-core snoops initiated by this Cbox due to processor core memory request. | |
| 22H | 80H | UNC_CBO_XSNP_RESPONSE.EVICTION_FILTER | Filter on cross-core snoops initiated by this Cbox due to LLC eviction. | |

Table 19-12. Non-Architectural Performance Events In the Processor Uncore for 2nd Generation Intel® Core™ i7-2xxx, Intel® Core™ i5-2xxx, Intel® Core™ i3-2xxx Processor Series (Contd.)

| Event Num.[1] | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 34H | 01H | UNC_CBO_CACHE_LOOKUP.M | LLC lookup request that access cache and found line in M-state. | Must combine with one of the umask values of 10H, 20H, 40H, 80H |
| 34H | 02H | UNC_CBO_CACHE_LOOKUP.E | LLC lookup request that access cache and found line in E-state. | |
| 34H | 04H | UNC_CBO_CACHE_LOOKUP.S | LLC lookup request that access cache and found line in S-state. | |
| 34H | 08H | UNC_CBO_CACHE_LOOKUP.I | LLC lookup request that access cache and found line in I-state. | |
| 34H | 10H | UNC_CBO_CACHE_LOOKUP.READ_FILTER | Filter on processor core initiated cacheable read requests. Must combine with at least one of 01H, 02H, 04H, 08H. | |
| 34H | 20H | UNC_CBO_CACHE_LOOKUP.WRITE_FILTER | Filter on processor core initiated cacheable write requests. Must combine with at least one of 01H, 02H, 04H, 08H. | |
| 34H | 40H | UNC_CBO_CACHE_LOOKUP.EXTSNP_FILTER | Filter on external snoop requests. Must combine with at least one of 01H, 02H, 04H, 08H. | |
| 34H | 80H | UNC_CBO_CACHE_LOOKUP.ANY_REQUEST_FILTER | Filter on any IRQ or IPQ initiated requests including uncacheable, non-coherent requests. Must combine with at least one of 01H, 02H, 04H, 08H. | |
| 80H | 01H | UNC_ARB_TRK_OCCUPANCY.ALL | Counts cycles weighted by the number of requests waiting for data returning from the memory controller. Accounts for coherent and non-coherent requests initiated by IA cores, processor graphic units, or LLC. | Counter 0 only |
| 81H | 01H | UNC_ARB_TRK_REQUEST.ALL | Counts the number of coherent and in-coherent requests initiated by IA cores, processor graphic units, or LLC. | |
| 81H | 20H | UNC_ARB_TRK_REQUEST.WRITES | Counts the number of allocated write entries, include full, partial, and LLC evictions. | |
| 81H | 80H | UNC_ARB_TRK_REQUEST.EVICTIONS | Counts the number of LLC evictions allocated. | |
| 83H | 01H | UNC_ARB_COH_TRK_OCCUPANCY.ALL | Cycles weighted by number of requests pending in Coherency Tracker. | Counter 0 only |
| 84H | 01H | UNC_ARB_COH_TRK_REQUEST.ALL | Number of requests allocated in Coherency Tracker. | |

NOTES:

1. The uncore events must be programmed using MSRs located in specific performance monitoring units in the uncore. UNC_CBO* events are supported using MSR_UNC_CBO* MSRs; UNC_ARB* events are supported using MSR_UNC_ARB*MSRs.

## 19.6 PERFORMANCE MONITORING EVENTS FOR INTEL® CORE™ I7 PROCESSOR FAMILY AND INTEL® XEON® PROCESSOR FAMILY

Processors based on the Intel microarchitecture code name Nehalem support the architectural and non-architectural performance-monitoring events listed in Table 19-1 and Table 19-13. The events in Table 19-13 generally applies to processors with CPUID signature of DisplayFamily_DisplayModel encoding with the following values: 06_1AH, 06_1EH, 06_1FH, and 06_2EH. However, Intel Xeon processors with CPUID signature of

DisplayFamily_DisplayModel 06_2EH have a small number of events that are not supported in processors with CPUID signature 06_1AH, 06_1EH, and 06_1FH. These events are noted in the comment column.

In addition, these processors (CPUID signature of DisplayFamily_DisplayModel 06_1AH, 06_1EH, 06_1FH) also support the following non-architectural, product-specific uncore performance-monitoring events listed in Table 19-14.

Fixed counters in the core PMU support the architecture events defined in Table 19-18.

### Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 04H | 07H | SB_DRAIN.ANY | Counts the number of store buffer drains. | |
| 06H | 04H | STORE_BLOCKS.AT_RET | Counts number of loads delayed with at-Retirement block code. The following loads need to be executed at retirement and wait for all senior stores on the same thread to be drained: load splitting across 4K boundary (page split), load accessing uncacheable (UC or USWC) memory, load lock, and load with page table in UC or USWC memory region. | |
| 06H | 08H | STORE_BLOCKS.L1D_BLOCK | Cacheable loads delayed with L1D block code. | |
| 07H | 01H | PARTIAL_ADDRESS_ALIAS | Counts false dependency due to partial address aliasing. | |
| 08H | 01H | DTLB_LOAD_MISSES.ANY | Counts all load misses that cause a page walk. | |
| 08H | 02H | DTLB_LOAD_MISSES.WALK_COMPLETED | Counts number of completed page walks due to load miss in the STLB. | |
| 08H | 10H | DTLB_LOAD_MISSES.STLB_HIT | Number of cache load STLB hits. | |
| 08H | 20H | DTLB_LOAD_MISSES.PDE_MISS | Number of DTLB cache load misses where the low part of the linear to physical address translation was missed. | |
| 08H | 80H | DTLB_LOAD_MISSES.LARGE_WALK_COMPLETED | Counts number of completed large page walks due to load miss in the STLB. | |
| 0BH | 01H | MEM_INST_RETIRED.LOADS | Counts the number of instructions with an architecturally-visible load retired on the architected path. | |
| 0BH | 02H | MEM_INST_RETIRED.STORES | Counts the number of instructions with an architecturally-visible store retired on the architected path. | |
| 0BH | 10H | MEM_INST_RETIRED.LATENCY_ABOVE_THRESHOLD | Counts the number of instructions exceeding the latency specified with ld_lat facility. | In conjunction with ld_lat facility |
| 0CH | 01H | MEM_STORE_RETIRED.DTLB_MISS | The event counts the number of retired stores that missed the DTLB. The DTLB miss is not counted if the store operation causes a fault. Does not counter prefetches. Counts both primary and secondary misses to the TLB. | |
| 0EH | 01H | UOPS_ISSUED.ANY | Counts the number of Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end. | |
| 0EH | 01H | UOPS_ISSUED.STALLED_CYCLES | Counts the number of cycles no Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end. | set “invert=1, cmask = 1” |

## Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 0EH | 02H | UOPS_ISSUED.FUSED | Counts the number of fused Uops that were issued from the Register Allocation Table to the Reservation Station. | |
| 0FH | 01H | MEM_UNCORE_RETIRED.L3_DATA_MISS_UNKNOWN | Counts number of memory load instructions retired where the memory reference missed L3 and data source is unknown. | Available only for CPUID signature 06_2EH |
| 0FH | 02H | MEM_UNCORE_RETIRED.OTHER_CORE_L2_HITM | Counts number of memory load instructions retired where the memory reference hit modified data in a sibling core residing on the same socket. | |
| 0FH | 08H | MEM_UNCORE_RETIRED.REMOTE_CACHE_LOCAL_HOME_HIT | Counts number of memory load instructions retired where the memory reference missed the L1, L2 and L3 caches and HIT in a remote socket's cache. Only counts locally homed lines. | |
| 0FH | 10H | MEM_UNCORE_RETIRED.REMOTE_DRAM | Counts number of memory load instructions retired where the memory reference missed the L1, L2 and L3 caches and was remotely homed. This includes both DRAM access and HITM in a remote socket's cache for remotely homed lines. | |
| 0FH | 20H | MEM_UNCORE_RETIRED.LOCAL_DRAM | Counts number of memory load instructions retired where the memory reference missed the L1, L2 and L3 caches and required a local socket memory reference. This includes locally homed cachelines that were in a modified state in another socket. | |
| 0FH | 80H | MEM_UNCORE_RETIRED.UNCACHEABLE | Counts number of memory load instructions retired where the memory reference missed the L1, L2 and L3 caches and to perform I/O. | Available only for CPUID signature 06_2EH |
| 10H | 01H | FP_COMP_OPS_EXE.X87 | Counts the number of FP Computational Uops Executed. The number of FADD, FSUB, FCOM, FMULs, integer MULsand IMULs, FDIVs, FPREMs, FSQRTS, integer DIVs, and IDIVs. This event does not distinguish an FADD used in the middle of a transcendental flow from a separate FADD instruction. | |
| 10H | 02H | FP_COMP_OPS_EXE.MMX | Counts number of MMX Uops executed. | |
| 10H | 04H | FP_COMP_OPS_EXE.SSE_FP | Counts number of SSE and SSE2 FP uops executed. | |
| 10H | 08H | FP_COMP_OPS_EXE.SSE2_INTEGER | Counts number of SSE2 integer uops executed. | |
| 10H | 10H | FP_COMP_OPS_EXE.SSE_FP_PACKED | Counts number of SSE FP packed uops executed. | |
| 10H | 20H | FP_COMP_OPS_EXE.SSE_FP_SCALAR | Counts number of SSE FP scalar uops executed. | |
| 10H | 40H | FP_COMP_OPS_EXE.SSE_SINGLE_PRECISION | Counts number of SSE* FP single precision uops executed. | |
| 10H | 80H | FP_COMP_OPS_EXE.SSE_DOUBLE_PRECISION | Counts number of SSE* FP double precision uops executed. | |
| 12H | 01H | SIMD_INT_128.PACKED_MPY | Counts number of 128 bit SIMD integer multiply operations. | |

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 12H | 02H | SIMD_INT_128.PACKED_SHIFT | Counts number of 128 bit SIMD integer shift operations. | |
| 12H | 04H | SIMD_INT_128.PACK | Counts number of 128 bit SIMD integer pack operations. | |
| 12H | 08H | SIMD_INT_128.UNPACK | Counts number of 128 bit SIMD integer unpack operations. | |
| 12H | 10H | SIMD_INT_128.PACKED_LOGICAL | Counts number of 128 bit SIMD integer logical operations. | |
| 12H | 20H | SIMD_INT_128.PACKED_ARITH | Counts number of 128 bit SIMD integer arithmetic operations. | |
| 12H | 40H | SIMD_INT_128.SHUFFLE_MOVE | Counts number of 128 bit SIMD integer shuffle and move operations. | |
| 13H | 01H | LOAD_DISPATCH.RS | Counts number of loads dispatched from the Reservation Station that bypass the Memory Order Buffer. | |
| 13H | 02H | LOAD_DISPATCH.RS_DELAYED | Counts the number of delayed RS dispatches at the stage latch. If an RS dispatch can not bypass to LB, it has another chance to dispatch from the one-cycle delayed staging latch before it is written into the LB. | |
| 13H | 04H | LOAD_DISPATCH.MOB | Counts the number of loads dispatched from the Reservation Station to the Memory Order Buffer. | |
| 13H | 07H | LOAD_DISPATCH.ANY | Counts all loads dispatched from the Reservation Station. | |
| 14H | 01H | ARITH.CYCLES_DIV_BUSY | Counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE.<br>Set 'edge =1, invert=1, cmask=1' to count the number of divides. | Count may be incorrect When SMT is on. |
| 14H | 02H | ARITH.MUL | Counts the number of multiply operations executed. This includes integer as well as floating point multiply operations but excludes DPPS mul and MPSAD. | Count may be incorrect When SMT is on |
| 17H | 01H | INST_QUEUE_WRITES | Counts the number of instructions written into the instruction queue every cycle. | |
| 18H | 01H | INST_DECODED.DEC0 | Counts number of instructions that require decoder 0 to be decoded. Usually, this means that the instruction maps to more than 1 uop. | |
| 19H | 01H | TWO_UOP_INSTS_DECODED | An instruction that generates two uops was decoded. | |

Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 1EH | 01H | INST_QUEUE_WRITE_CYCLES | This event counts the number of cycles during which instructions are written to the instruction queue. Dividing this counter by the number of instructions written to the instruction queue (INST_QUEUE_WRITES) yields the average number of instructions decoded each cycle. If this number is less than four and the pipe stalls, this indicates that the decoder is failing to decode enough instructions per cycle to sustain the 4-wide pipeline. | If SSE* instructions that are 6 bytes or longer arrive one after another, then front end throughput may limit execution speed. |
| 20H | 01H | LSD_OVERFLOW | Counts number of loops that can't stream from the instruction queue. | |
| 24H | 01H | L2_RQSTS.LD_HIT | Counts number of loads that hit the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches. L2 loads can be rejected for various reasons. Only non rejected loads are counted. | |
| 24H | 02H | L2_RQSTS.LD_MISS | Counts the number of loads that miss the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches. | |
| 24H | 03H | L2_RQSTS.LOADS | Counts all L2 load requests. L2 loads include both L1D demand misses as well as L1D prefetches. | |
| 24H | 04H | L2_RQSTS.RFO_HIT | Counts the number of store RFO requests that hit the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches. Count includes WC memory requests, where the data is not fetched but the permission to write the line is required. | |
| 24H | 08H | L2_RQSTS.RFO_MISS | Counts the number of store RFO requests that miss the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches. | |
| 24H | 0CH | L2_RQSTS.RFOS | Counts all L2 store RFO requests. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches. | |
| 24H | 10H | L2_RQSTS.IFETCH_HIT | Counts number of instruction fetches that hit the L2 cache. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches. | |
| 24H | 20H | L2_RQSTS.IFETCH_MISS | Counts number of instruction fetches that miss the L2 cache. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches. | |
| 24H | 30H | L2_RQSTS.IFETCHES | Counts all instruction fetches. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches. | |
| 24H | 40H | L2_RQSTS.PREFETCH_HIT | Counts L2 prefetch hits for both code and data. | |
| 24H | 80H | L2_RQSTS.PREFETCH_MISS | Counts L2 prefetch misses for both code and data. | |
| 24H | C0H | L2_RQSTS.PREFETCHES | Counts all L2 prefetches for both code and data. | |
| 24H | AAH | L2_RQSTS.MISS | Counts all L2 misses for both code and data. | |

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 24H | FFH | L2_RQSTS.REFERENCES | Counts all L2 requests for both code and data. | |
| 26H | 01H | L2_DATA_RQSTS.DEMAND.I_STATE | Counts number of L2 data demand loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 02H | L2_DATA_RQSTS.DEMAND.S_STATE | Counts number of L2 data demand loads where the cache line to be loaded is in the S (shared) state. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 04H | L2_DATA_RQSTS.DEMAND.E_STATE | Counts number of L2 data demand loads where the cache line to be loaded is in the E (exclusive) state. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 08H | L2_DATA_RQSTS.DEMAND.M_STATE | Counts number of L2 data demand loads where the cache line to be loaded is in the M (modified) state. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 0FH | L2_DATA_RQSTS.DEMAND.MESI | Counts all L2 data demand requests. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 10H | L2_DATA_RQSTS.PREFETCH.I_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. | |
| 26H | 20H | L2_DATA_RQSTS.PREFETCH.S_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the S (shared) state. A prefetch RFO will miss on an S state line, while a prefetch read will hit on an S state line. | |
| 26H | 40H | L2_DATA_RQSTS.PREFETCH.E_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the E (exclusive) state. | |
| 26H | 80H | L2_DATA_RQSTS.PREFETCH.M_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the M (modified) state. | |
| 26H | F0H | L2_DATA_RQSTS.PREFETCH.MESI | Counts all L2 prefetch requests. | |
| 26H | FFH | L2_DATA_RQSTS.ANY | Counts all L2 data requests. | |
| 27H | 01H | L2_WRITE.RFO.I_STATE | Counts number of L2 demand store RFO requests where the cache line to be loaded is in the I (invalid) state, i.e, a cache miss. The L1D prefetcher does not issue a RFO prefetch. | This is a demand RFO request |
| 27H | 02H | L2_WRITE.RFO.S_STATE | Counts number of L2 store RFO requests where the cache line to be loaded is in the S (shared) state. The L1D prefetcher does not issue a RFO prefetch,. | This is a demand RFO request |
| 27H | 08H | L2_WRITE.RFO.M_STATE | Counts number of L2 store RFO requests where the cache line to be loaded is in the M (modified) state. The L1D prefetcher does not issue a RFO prefetch. | This is a demand RFO request |
| 27H | 0EH | L2_WRITE.RFO.HIT | Counts number of L2 store RFO requests where the cache line to be loaded is in either the S, E or M states. The L1D prefetcher does not issue a RFO prefetch. | This is a demand RFO request |

## Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 27H | 0FH | L2_WRITE.RFO.MESI | Counts all L2 store RFO requests.The L1D prefetcher does not issue a RFO prefetch. | This is a demand RFO request |
| 27H | 10H | L2_WRITE.LOCK.I_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. | |
| 27H | 20H | L2_WRITE.LOCK.S_STATE | Counts number of L2 lock RFO requests where the cache line to be loaded is in the S (shared) state. | |
| 27H | 40H | L2_WRITE.LOCK.E_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the E (exclusive) state. | |
| 27H | 80H | L2_WRITE.LOCK.M_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the M (modified) state. | |
| 27H | E0H | L2_WRITE.LOCK.HIT | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in either the S, E, or M state. | |
| 27H | F0H | L2_WRITE.LOCK.MESI | Counts all L2 demand lock RFO requests. | |
| 28H | 01H | L1D_WB_L2.I_STATE | Counts number of L1 writebacks to the L2 where the cache line to be written is in the I (invalid) state, i.e. a cache miss. | |
| 28H | 02H | L1D_WB_L2.S_STATE | Counts number of L1 writebacks to the L2 where the cache line to be written is in the S state. | |
| 28H | 04H | L1D_WB_L2.E_STATE | Counts number of L1 writebacks to the L2 where the cache line to be written is in the E (exclusive) state. | |
| 28H | 08H | L1D_WB_L2.M_STATE | Counts number of L1 writebacks to the L2 where the cache line to be written is in the M (modified) state. | |
| 28H | 0FH | L1D_WB_L2.MESI | Counts all L1 writebacks to the L2 . | |
| 2EH | 4FH | L3_LAT_CACHE.REFERENCE | This event counts requests originating from the core that reference a cache line in the last level cache. The event count includes speculative traffic but excludes cache line fills due to a L2 hardware-prefetch. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended. | see Table 19-1 |
| 2EH | 41H | L3_LAT_CACHE.MISS | This event counts each cache miss condition for references to the last level cache. The event count may include speculative traffic but excludes cache line fills due to L2 hardware-prefetches. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended. | see Table 19-1 |

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 3CH | 00H | CPU_CLK_UNHALTED.THREAD_P | Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling. | see Table 19-1 |
| 3CH | 01H | CPU_CLK_UNHALTED.REF_P | Increments at the frequency of TSC when not halted. | see Table 19-1 |
| 40H | 01H | L1D_CACHE_LD.I_STATE | Counts L1 data cache read requests where the cache line to be loaded is in the I (invalid) state, i.e. the read request missed the cache. | Counter 0, 1 only |
| 40H | 02H | L1D_CACHE_LD.S_STATE | Counts L1 data cache read requests where the cache line to be loaded is in the S (shared) state. | Counter 0, 1 only |
| 40H | 04H | L1D_CACHE_LD.E_STATE | Counts L1 data cache read requests where the cache line to be loaded is in the E (exclusive) state. | Counter 0, 1 only |
| 40H | 08H | L1D_CACHE_LD.M_STATE | Counts L1 data cache read requests where the cache line to be loaded is in the M (modified) state. | Counter 0, 1 only |
| 40H | 0FH | L1D_CACHE_LD.MESI | Counts L1 data cache read requests. | Counter 0, 1 only |
| 41H | 02H | L1D_CACHE_ST.S_STATE | Counts L1 data cache store RFO requests where the cache line to be loaded is in the S (shared) state. | Counter 0, 1 only |
| 41H | 04H | L1D_CACHE_ST.E_STATE | Counts L1 data cache store RFO requests where the cache line to be loaded is in the E (exclusive) state. | Counter 0, 1 only |
| 41H | 08H | L1D_CACHE_ST.M_STATE | Counts L1 data cache store RFO requests where cache line to be loaded is in the M (modified) state. | Counter 0, 1 only |
| 42H | 01H | L1D_CACHE_LOCK.HIT | Counts retired load locks that hit in the L1 data cache or hit in an already allocated fill buffer. The lock portion of the load lock transaction must hit in the L1D. | The initial load will pull the lock into the L1 data cache. Counter 0, 1 only |
| 42H | 02H | L1D_CACHE_LOCK.S_STATE | Counts L1 data cache retired load locks that hit the target cache line in the shared state. | Counter 0, 1 only |
| 42H | 04H | L1D_CACHE_LOCK.E_STATE | Counts L1 data cache retired load locks that hit the target cache line in the exclusive state. | Counter 0, 1 only |
| 42H | 08H | L1D_CACHE_LOCK.M_STATE | Counts L1 data cache retired load locks that hit the target cache line in the modified state. | Counter 0, 1 only |
| 43H | 01H | L1D_ALL_REF.ANY | Counts all references (uncached, speculated and retired) to the L1 data cache, including all loads and stores with any memory types. The event counts memory accesses only when they are actually performed. For example, a load blocked by unknown store address and later performed is only counted once. | The event does not include non-memory accesses, such as I/O accesses. Counter 0, 1 only |
| 43H | 02H | L1D_ALL_REF.CACHEABLE | Counts all data reads and writes (speculated and retired) from cacheable memory, including locked operations. | Counter 0, 1 only |
| 49H | 01H | DTLB_MISSES.ANY | Counts the number of misses in the STLB which causes a page walk. | |
| 49H | 02H | DTLB_MISSES.WALK_COMPLETED | Counts number of misses in the STLB which resulted in a completed page walk. | |

## Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 49H | 10H | DTLB_MISSES.STLB_HIT | Counts the number of DTLB first level misses that hit in the second level TLB. This event is only relevant if the core contains multiple DTLB levels. | |
| 49H | 20H | DTLB_MISSES.PDE_MISS | Number of DTLB misses caused by low part of address, includes references to 2M pages because 2M pages do not use the PDE. | |
| 49H | 80H | DTLB_MISSES.LARGE_WALK_COMPLETED | Counts number of misses in the STLB which resulted in a completed page walk for large pages. | |
| 4CH | 01H | LOAD_HIT_PRE | Counts load operations sent to the L1 data cache while a previous SSE prefetch instruction to the same cache line has started prefetching but has not yet finished. | |
| 4EH | 01H | L1D_PREFETCH.REQUESTS | Counts number of hardware prefetch requests dispatched out of the prefetch FIFO. | |
| 4EH | 02H | L1D_PREFETCH.MISS | Counts number of hardware prefetch requests that miss the L1D. There are two prefetchers in the L1D. A streamer, which predicts lines sequentially after this one should be fetched, and the IP prefetcher that remembers access patterns for the current instruction. The streamer prefetcher stops on an L1D hit, while the IP prefetcher does not. | |
| 4EH | 04H | L1D_PREFETCH.TRIGGERS | Counts number of prefetch requests triggered by the Finite State Machine and pushed into the prefetch FIFO. Some of the prefetch requests are dropped due to overwrites or competition between the IP index prefetcher and streamer prefetcher. The prefetch FIFO contains 4 entries. | |
| 51H | 01H | L1D.REPL | Counts the number of lines brought into the L1 data cache. | Counter 0, 1 only |
| 51H | 02H | L1D.M_REPL | Counts the number of modified lines brought into the L1 data cache. | Counter 0, 1 only |
| 51H | 04H | L1D.M_EVICT | Counts the number of modified lines evicted from the L1 data cache due to replacement. | Counter 0, 1 only |
| 51H | 08H | L1D.M_SNOOP_EVICT | Counts the number of modified lines evicted from the L1 data cache due to snoop HITM intervention. | Counter 0, 1 only |
| 52H | 01H | L1D_CACHE_PREFETCH_LOCK_FB_HIT | Counts the number of cacheable load lock speculated instructions accepted into the fill buffer. | |
| 53H | 01H | L1D_CACHE_LOCK_FB_HIT | Counts the number of cacheable load lock speculated or retired instructions accepted into the fill buffer. | |
| 63H | 01H | CACHE_LOCK_CYCLES.L1D_L2 | Cycle count during which the L1D and L2 are locked. A lock is asserted when there is a locked memory access, due to uncacheable memory, a locked operation that spans two cache lines, or a page walk from an uncacheable page table. | Counter 0, 1 only. L1D and L2 locks have a very high performance penalty and it is highly recommended to avoid such accesses. |
| 63H | 02H | CACHE_LOCK_CYCLES.L1D | Counts the number of cycles that cacheline in the L1 data cache unit is locked. | Counter 0, 1 only. |

### Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 6CH | 01H | IO_TRANSACTIONS | Counts the number of completed I/O transactions. | |
| 80H | 01H | L1I.HITS | Counts all instruction fetches that hit the L1 instruction cache. | |
| 80H | 02H | L1I.MISSES | Counts all instruction fetches that miss the L1I cache. This includes instruction cache misses, streaming buffer misses, victim cache misses and uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding. | |
| 80H | 03H | L1I.READS | Counts all instruction fetches, including uncacheable fetches that bypass the L1I. | |
| 80H | 04H | L1I.CYCLES_STALLED | Cycle counts for which an instruction fetch stalls due to a L1I cache miss, ITLB miss or ITLB fault. | |
| 82H | 01H | LARGE_ITLB.HIT | Counts number of large ITLB hits. | |
| 85H | 01H | ITLB_MISSES.ANY | Counts the number of misses in all levels of the ITLB which causes a page walk. | |
| 85H | 02H | ITLB_MISSES.WALK_COMPLETED | Counts number of misses in all levels of the ITLB which resulted in a completed page walk. | |
| 87H | 01H | ILD_STALL.LCP | Cycles Instruction Length Decoder stalls due to length changing prefixes: 66, 67 or REX.W (for EM64T) instructions which change the length of the decoded instruction. | |
| 87H | 02H | ILD_STALL.MRU | Instruction Length Decoder stall cycles due to Brand Prediction Unit (PBU) Most Recently Used (MRU) bypass. | |
| 87H | 04H | ILD_STALL.IQ_FULL | Stall cycles due to a full instruction queue. | |
| 87H | 08H | ILD_STALL.REGEN | Counts the number of regen stalls. | |
| 87H | 0FH | ILD_STALL.ANY | Counts any cycles the Instruction Length Decoder is stalled. | |
| 88H | 01H | BR_INST_EXEC.COND | Counts the number of conditional near branch instructions executed, but not necessarily retired. | |
| 88H | 02H | BR_INST_EXEC.DIRECT | Counts all unconditional near branch instructions excluding calls and indirect branches. | |
| 88H | 04H | BR_INST_EXEC.INDIRECT_NON_CALL | Counts the number of executed indirect near branch instructions that are not calls. | |
| 88H | 07H | BR_INST_EXEC.NON_CALLS | Counts all non call near branch instructions executed, but not necessarily retired. | |
| 88H | 08H | BR_INST_EXEC.RETURN_NEAR | Counts indirect near branches that have a return mnemonic. | |
| 88H | 10H | BR_INST_EXEC.DIRECT_NEAR_CALL | Counts unconditional near call branch instructions, excluding non call branch, executed. | |
| 88H | 20H | BR_INST_EXEC.INDIRECT_NEAR_CALL | Counts indirect near calls, including both register and memory indirect, executed. | |
| 88H | 30H | BR_INST_EXEC.NEAR_CALLS | Counts all near call branches executed, but not necessarily retired. | |

Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 88H | 40H | BR_INST_EXEC.TAKEN | Counts taken near branches executed, but not necessarily retired. | |
| 88H | 7FH | BR_INST_EXEC.ANY | Counts all near executed branches (not necessarily retired). This includes only instructions and not micro-op branches. Frequent branching is not necessarily a major performance issue. However frequent branch mispredictions may be a problem. | |
| 89H | 01H | BR_MISP_EXEC.COND | Counts the number of mispredicted conditional near branch instructions executed, but not necessarily retired. | |
| 89H | 02H | BR_MISP_EXEC.DIRECT | Counts mispredicted macro unconditional near branch instructions, excluding calls and indirect branches (should always be 0). | |
| 89H | 04H | BR_MISP_EXEC.INDIRECT_NON_CALL | Counts the number of executed mispredicted indirect near branch instructions that are not calls. | |
| 89H | 07H | BR_MISP_EXEC.NON_CALLS | Counts mispredicted non call near branches executed, but not necessarily retired. | |
| 89H | 08H | BR_MISP_EXEC.RETURN_NEAR | Counts mispredicted indirect branches that have a rear return mnemonic. | |
| 89H | 10H | BR_MISP_EXEC.DIRECT_NEAR_CALL | Counts mispredicted non-indirect near calls executed, (should always be 0). | |
| 89H | 20H | BR_MISP_EXEC.INDIRECT_NEAR_CALL | Counts mispredicted indirect near calls exeucted, including both register and memory indirect. | |
| 89H | 30H | BR_MISP_EXEC.NEAR_CALLS | Counts all mispredicted near call branches executed, but not necessarily retired. | |
| 89H | 40H | BR_MISP_EXEC.TAKEN | Counts executed mispredicted near branches that are taken, but not necessarily retired. | |
| 89H | 7FH | BR_MISP_EXEC.ANY | Counts the number of mispredicted near branch instructions that were executed, but not necessarily retired. | |
| A2H | 01H | RESOURCE_STALLS.ANY | Counts the number of Allocator resource related stalls. Includes register renaming buffer entries, memory buffer entries. In addition to resource related stalls, this event counts some other events. Includes stalls arising during branch misprediction recovery, such as if retirement of the mispredicted branch is delayed and stalls arising while store buffer is draining from synchronizing operations. | Does not include stalls due to SuperQ (off core) queue full, too many cache misses, etc. |
| A2H | 02H | RESOURCE_STALLS.LOAD | Counts the cycles of stall due to lack of load buffer for load operation. | |
| A2H | 04H | RESOURCE_STALLS.RS_FULL | This event counts the number of cycles when the number of instructions in the pipeline waiting for execution reaches the limit the processor can handle. A high count of this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, or instructions dependent upon instructions further down the pipeline that have yet to retire. | When RS is full, new instructions can not enter the reservation station and start execution. |

### Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| A2H | 08H | RESOURCE_STALLS.STORE | This event counts the number of cycles that a resource related stall will occur due to the number of store instructions reaching the limit of the pipeline, (i.e. all store buffers are used). The stall ends when a store instruction commits its data to the cache or memory. | |
| A2H | 10H | RESOURCE_STALLS.ROB_FULL | Counts the cycles of stall due to re-order buffer full. | |
| A2H | 20H | RESOURCE_STALLS.FPCW | Counts the number of cycles while execution was stalled due to writing the floating-point unit (FPU) control word. | |
| A2H | 40H | RESOURCE_STALLS.MXCSR | Stalls due to the MXCSR register rename occurring to close to a previous MXCSR rename. The MXCSR provides control and status for the MMX registers. | |
| A2H | 80H | RESOURCE_STALLS.OTHER | Counts the number of cycles while execution was stalled due to other resource issues. | |
| A6H | 01H | MACRO_INSTS.FUSIONS_DECODED | Counts the number of instructions decoded that are macro-fused but not necessarily executed or retired. | |
| A7H | 01H | BACLEAR_FORCE_IQ | Counts number of times a BACLEAR was forced by the Instruction Queue. The IQ is also responsible for providing conditional branch prediciton direction based on a static scheme and dynamic data provided by the L2 Branch Prediction Unit. If the conditional branch target is not found in the Target Array and the IQ predicts that the branch is taken, then the IQ will force the Branch Address Calculator to issue a BACLEAR. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. | |
| A8H | 01H | LSD.UOPS | Counts the number of micro-ops delivered by loop stream detector. | Use cmask=1 and invert to count cycles |
| AEH | 01H | ITLB_FLUSH | Counts the number of ITLB flushes. | |
| B0H | 40H | OFFCORE_REQUESTS.L1D_WRITEBACK | Counts number of L1D writebacks to the uncore. | |
| B1H | 01H | UOPS_EXECUTED.PORT0 | Counts number of Uops executed that were issued on port 0. Port 0 handles integer arithmetic, SIMD and FP add Uops. | |
| B1H | 02H | UOPS_EXECUTED.PORT1 | Counts number of Uops executed that were issued on port 1. Port 1 handles integer arithmetic, SIMD, integer shift, FP multiply and FP divide Uops. | |
| B1H | 04H | UOPS_EXECUTED.PORT2_CORE | Counts number of Uops executed that were issued on port 2. Port 2 handles the load Uops. This is a core count only and can not be collected per thread. | |
| B1H | 08H | UOPS_EXECUTED.PORT3_CORE | Counts number of Uops executed that were issued on port 3. Port 3 handles store Uops. This is a core count only and can not be collected per thread. | |

## Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| B1H | 10H | UOPS_EXECUTED.PORT4_CORE | Counts number of Uops executed that where issued on port 4. Port 4 handles the value to be stored for the store Uops issued on port 3. This is a core count only and can not be collected per thread. | |
| B1H | 1FH | UOPS_EXECUTED.CORE_ACTIVE_CYCLES_NO_PORT5 | Counts cycles when the Uops executed were issued from any ports except port 5. Use Cmask=1 for active cycles; Cmask=0 for weighted cycles; Use CMask=1, Invert=1 to count P0-4 stalled cycles Use Cmask=1, Edge=1, Invert=1 to count P0-4 stalls. | |
| B1H | 20H | UOPS_EXECUTED.PORT5 | Counts number of Uops executed that where issued on port 5. | |
| B1H | 3FH | UOPS_EXECUTED.CORE_ACTIVE_CYCLES | Counts cycles when the Uops are executing . Use Cmask=1 for active cycles; Cmask=0 for weighted cycles; Use CMask=1, Invert=1 to count P0-4 stalled cycles Use Cmask=1, Edge=1, Invert=1 to count P0-4 stalls. | |
| B1H | 40H | UOPS_EXECUTED.PORT015 | Counts number of Uops executed that where issued on port 0, 1, or 5. | use cmask=1, invert=1 to count stall cycles |
| B1H | 80H | UOPS_EXECUTED.PORT234 | Counts number of Uops executed that where issued on port 2, 3, or 4. | |
| B2H | 01H | OFFCORE_REQUESTS_SQ_FULL | Counts number of cycles the SQ is full to handle off-core requests. | |
| B7H | 01H | OFF_CORE_RESPONSE_0 | see Section 18.7.1.3, "Off-core Response Performance Monitoring in the Processor Core". | Requires programming MSR 01A6H |
| B8H | 01H | SNOOP_RESPONSE.HIT | Counts HIT snoop response sent by this thread in response to a snoop request. | |
| B8H | 02H | SNOOP_RESPONSE.HITE | Counts HIT E snoop response sent by this thread in response to a snoop request. | |
| B8H | 04H | SNOOP_RESPONSE.HITM | Counts HIT M snoop response sent by this thread in response to a snoop request. | |
| BBH | 01H | OFF_CORE_RESPONSE_1 | See Section 18.8, "Performance Monitoring for Processors Based on Intel® Microarchitecture Code Name Westmere". | Requires programming MSR 01A7H |
| C0H | 00H | INST_RETIRED.ANY_P | See Table 19-1<br>Notes: INST_RETIRED.ANY is counted by a designated fixed counter. INST_RETIRED.ANY_P is counted by a programmable counter and is an architectural performance event. Event is supported if CPUID.A.EBX[1] = 0. | Counting: Faulting executions of GETSEC/VM entry/VM Exit/MWait will not count as retired instructions. |
| C0H | 02H | INST_RETIRED.X87 | Counts the number of MMX instructions retired. | |
| C0H | 04H | INST_RETIRED.MMX | Counts the number of floating point computational operations retired: floating point computational operations executed by the assist handler and sub-operations of complex floating point instructions like transcendental instructions. | |

### Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| C2H | 01H | UOPS_RETIRED.ANY | Counts the number of micro-ops retired, (macro-fused=1, micro-fused=2, others=1; maximum count of 8 per cycle). Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. | Use cmask=1 and invert to count active cycles or stalled cycles |
| C2H | 02H | UOPS_RETIRED.RETIRE_SLOTS | Counts the number of retirement slots used each cycle. | |
| C2H | 04H | UOPS_RETIRED.MACRO_FUSED | Counts number of macro-fused uops retired. | |
| C3H | 01H | MACHINE_CLEARS.CYCLES | Counts the cycles machine clear is asserted. | |
| C3H | 02H | MACHINE_CLEARS.MEM_ORDER | Counts the number of machine clears due to memory order conflicts. | |
| C3H | 04H | MACHINE_CLEARS.SMC | Counts the number of times that a program writes to a code section. Self-modifying code causes a sever penalty in all Intel 64 and IA-32 processors. The modified cache line is written back to the L2 and L3caches. | |
| C4H | 00H | BR_INST_RETIRED.ALL_BRANCHES | Branch instructions at retirement | See Table 19-1 |
| C4H | 01H | BR_INST_RETIRED.CONDITIONAL | Counts the number of conditional branch instructions retired. | |
| C4H | 02H | BR_INST_RETIRED.NEAR_CALL | Counts the number of direct & indirect near unconditional calls retired. | |
| C5H | 00H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted branch instructions at retirement | See Table 19-1 |
| C5H | 02H | BR_MISP_RETIRED.NEAR_CALL | Counts mispredicted direct & indirect near unconditional retired calls. | |
| C7H | 01H | SSEX_UOPS_RETIRED.PACKED_SINGLE | Counts SIMD packed single-precision floating point Uops retired. | |
| C7H | 02H | SSEX_UOPS_RETIRED.SCALAR_SINGLE | Counts SIMD calar single-precision floating point Uops retired. | |
| C7H | 04H | SSEX_UOPS_RETIRED.PACKED_DOUBLE | Counts SIMD packed double-precision floating point Uops retired. | |
| C7H | 08H | SSEX_UOPS_RETIRED.SCALAR_DOUBLE | Counts SIMD scalar double-precision floating point Uops retired. | |
| C7H | 10H | SSEX_UOPS_RETIRED.VECTOR_INTEGER | Counts 128-bit SIMD vector integer Uops retired. | |
| C8H | 20H | ITLB_MISS_RETIRED | Counts the number of retired instructions that missed the ITLB when the instruction was fetched. | |
| CBH | 01H | MEM_LOAD_RETIRED.L1D_HIT | Counts number of retired loads that hit the L1 data cache. | |
| CBH | 02H | MEM_LOAD_RETIRED.L2_HIT | Counts number of retired loads that hit the L2 data cache. | |
| CBH | 04H | MEM_LOAD_RETIRED.L3_UNSHARED_HIT | Counts number of retired loads that hit their own, unshared lines in the L3 cache. | |

## Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| CBH | 08H | MEM_LOAD_RETIRED.OTHER_CORE_L2_HIT_HITM | Counts number of retired loads that hit in a sibling core's L2 (on die core). Since the L3 is inclusive of all cores on the package, this is an L3 hit. This counts both clean or modified hits. | |
| CBH | 10H | MEM_LOAD_RETIRED.L3_MISS | Counts number of retired loads that miss the L3 cache. The load was satisfied by a remote socket, local memory or an IOH. | |
| CBH | 40H | MEM_LOAD_RETIRED.HIT_LFB | Counts number of retired loads that miss the L1D and the address is located in an allocated line fill buffer and will soon be committed to cache. This is counting secondary L1D misses. | |
| CBH | 80H | MEM_LOAD_RETIRED.DTLB_MISS | Counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault. This event counts loads from cacheable memory only. The event does not count loads by software prefetches. Counts both primary and secondary misses to the TLB. | |
| CCH | 01H | FP_MMX_TRANS.TO_FP | Counts the first floating-point instruction following any MMX instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states. | |
| CCH | 02H | FP_MMX_TRANS.TO_MMX | Counts the first MMX instruction following a floating-point instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states. | |
| CCH | 03H | FP_MMX_TRANS.ANY | Counts all transitions from floating point to MMX instructions and from MMX instructions to floating point instructions. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states. | |
| D0H | 01H | MACRO_INSTS.DECODED | Counts the number of instructions decoded, (but not necessarily executed or retired). | |
| D1H | 02H | UOPS_DECODED.MS | Counts the number of Uops decoded by the Microcode Sequencer, MS. The MS delivers uops when the instruction is more than 4 uops long or a microcode assist is occurring. | |
| D1H | 04H | UOPS_DECODED.ESP_FOLDING | Counts number of stack pointer (ESP) instructions decoded: push , pop , call , ret, etc. ESP instructions do not generate a Uop to increment or decrement ESP. Instead, they update an ESP_Offset register that keeps track of the delta to the current value of the ESP register. | |
| D1H | 08H | UOPS_DECODED.ESP_SYNC | Counts number of stack pointer (ESP) sync operations where an ESP instruction is corrected by adding the ESP offset register to the current value of the ESP register. | |

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| D2H | 01H | RAT_STALLS.FLAGS | Counts the number of cycles during which execution stalled due to several reasons, one of which is a partial flag register stall. A partial register stall may occur when two conditions are met: 1) an instruction modifies some, but not all, of the flags in the flag register and 2) the next instruction, which depends on flags, depends on flags that were not modified by this instruction. | |
| D2H | 02H | RAT_STALLS.REGISTERS | This event counts the number of cycles instruction execution latency became longer than the defined latency because the instruction used a register that was partially written by previous instruction. | |
| D2H | 04H | RAT_STALLS.ROB_READ_PORT | Counts the number of cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the out-of-order pipeline. Note that, at this stage in the pipeline, additional stalls may occur at the same cycle and prevent the stalled micro-ops from entering the pipe. In such a case, micro-ops retry entering the execution pipe in the next cycle and the ROB-read port stall is counted again. | |
| D2H | 08H | RAT_STALLS.SCOREBOARD | Counts the cycles where we stall due to microarchitecturally required serialization. Microcode scoreboarding stalls. | |
| D2H | 0FH | RAT_STALLS.ANY | Counts all Register Allocation Table stall cycles due to: Cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the execution pipe. Cycles when partial register stalls occurred Cycles when flag stalls occurred Cycles floating-point unit (FPU) status word stalls occurred. To count each of these conditions separately use the events: RAT_STALLS.ROB_READ_PORT, RAT_STALLS.PARTIAL, RAT_STALLS.FLAGS, and RAT_STALLS.FPSW. | |
| D4H | 01H | SEG_RENAME_STALLS | Counts the number of stall cycles due to the lack of renaming resources for the ES, DS, FS, and GS segment registers. If a segment is renamed but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires. | |
| D5H | 01H | ES_REG_RENAMES | Counts the number of times the ES segment register is renamed. | |
| DBH | 01H | UOP_UNFUSION | Counts unfusion events due to floating point exception to a fused uop. | |
| E0H | 01H | BR_INST_DECODED | Counts the number of branch instructions decoded. | |
| E5H | 01H | BPU_MISSED_CALL_RET | Counts number of times the Branch Prediction Unit missed predicting a call or return branch. | |

## Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| E6H | 01H | BACLEAR.CLEAR | Counts the number of times the front end is resteered, mainly when the Branch Prediction Unit cannot provide a correct prediction and this is corrected by the Branch Address Calculator at the front end. This can occur if the code has many branches such that they cannot be consumed by the BPU. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. The effect on total execution time depends on the surrounding code. | |
| E6H | 02H | BACLEAR.BAD_TARGET | Counts number of Branch Address Calculator clears (BACLEAR) asserted due to conditional branch instructions in which there was a target hit but the direction was wrong. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. | |
| E8H | 01H | BPU_CLEARS.EARLY | Counts early (normal) Branch Prediction Unit clears: BPU predicted a taken branch after incorrectly assuming that it was not taken. | The BPU clear leads to 2 cycle bubble in the Front End. |
| E8H | 02H | BPU_CLEARS.LATE | Counts late Branch Prediction Unit clears due to Most Recently Used conflicts. The PBU clear leads to a 3 cycle bubble in the Front End. | |
| F0H | 01H | L2_TRANSACTIONS.LOAD | Counts L2 load operations due to HW prefetch or demand loads. | |
| F0H | 02H | L2_TRANSACTIONS.RFO | Counts L2 RFO operations due to HW prefetch or demand RFOs. | |
| F0H | 04H | L2_TRANSACTIONS.IFETCH | Counts L2 instruction fetch operations due to HW prefetch or demand ifetch. | |
| F0H | 08H | L2_TRANSACTIONS.PREFETCH | Counts L2 prefetch operations. | |
| F0H | 10H | L2_TRANSACTIONS.L1D_WB | Counts L1D writeback operations to the L2. | |
| F0H | 20H | L2_TRANSACTIONS.FILL | Counts L2 cache line fill operations due to load, RFO, L1D writeback or prefetch. | |
| F0H | 40H | L2_TRANSACTIONS.WB | Counts L2 writeback operations to the L3. | |
| F0H | 80H | L2_TRANSACTIONS.ANY | Counts all L2 cache operations. | |
| F1H | 02H | L2_LINES_IN.S_STATE | Counts the number of cache lines allocated in the L2 cache in the S (shared) state. | |
| F1H | 04H | L2_LINES_IN.E_STATE | Counts the number of cache lines allocated in the L2 cache in the E (exclusive) state. | |
| F1H | 07H | L2_LINES_IN.ANY | Counts the number of cache lines allocated in the L2 cache. | |
| F2H | 01H | L2_LINES_OUT.DEMAND_CLEAN | Counts L2 clean cache lines evicted by a demand request. | |
| F2H | 02H | L2_LINES_OUT.DEMAND_DIRTY | Counts L2 dirty (modified) cache lines evicted by a demand request. | |
| F2H | 04H | L2_LINES_OUT.PREFETCH_CLEAN | Counts L2 clean cache line evicted by a prefetch request. | |

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| F2H | 08H | L2_LINES_OUT.PREFETCH_DIRTY | Counts L2 modified cache line evicted by a prefetch request. | |
| F2H | 0FH | L2_LINES_OUT.ANY | Counts all L2 cache lines evicted for any reason. | |
| F4H | 10H | SQ_MISC.SPLIT_LOCK | Counts the number of SQ lock splits across a cache line. | |
| F6H | 01H | SQ_FULL_STALL_CYCLES | Counts cycles the Super Queue is full. Neither of the threads on this core will be able to access the uncore. | |
| F7H | 01H | FP_ASSIST.ALL | Counts the number of floating point operations executed that required micro-code assist intervention. Assists are required in the following cases: SSE instructions, (Denormal input when the DAZ flag is off or Underflow result when the FTZ flag is off): x87 instructions, (NaN or denormal are loaded to a register or used as input from memory, Division by 0 or Underflow output). | |
| F7H | 02H | FP_ASSIST.OUTPUT | Counts number of floating point micro-code assist when the output value (destination register) is invalid. | |
| F7H | 04H | FP_ASSIST.INPUT | Counts number of floating point micro-code assist when the input value (one of the source operands to an FP instruction) is invalid. | |
| FDH | 01H | SIMD_INT_64.PACKED_MPY | Counts number of SID integer 64 bit packed multiply operations. | |
| FDH | 02H | SIMD_INT_64.PACKED_SHIFT | Counts number of SID integer 64 bit packed shift operations. | |
| FDH | 04H | SIMD_INT_64.PACK | Counts number of SID integer 64 bit pack operations. | |
| FDH | 08H | SIMD_INT_64.UNPACK | Counts number of SID integer 64 bit unpack operations. | |
| FDH | 10H | SIMD_INT_64.PACKED_LOGICAL | Counts number of SID integer 64 bit logical operations. | |
| FDH | 20H | SIMD_INT_64.PACKED_ARITH | Counts number of SID integer 64 bit arithmetic operations. | |
| FDH | 40H | SIMD_INT_64.SHUFFLE_MOVE | Counts number of SID integer 64 bit shift or move operations. | |

Non-architectural Performance monitoring events that are located in the uncore sub-system are implementation specific between different platforms using processors based on Intel microarchitecture code name Nehalem. Processors with CPUID signature of DisplayFamily_DisplayModel 06_1AH, 06_1EH, and 06_1FH support performance events listed in Table 19-14.

### Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 00H | 01H | UNC_GQ_CYCLES_FULL.READ_TRACKER | Uncore cycles Global Queue read tracker is full. | |
| 00H | 02H | UNC_GQ_CYCLES_FULL.WRITE_TRACKER | Uncore cycles Global Queue write tracker is full. | |
| 00H | 04H | UNC_GQ_CYCLES_FULL.PEER_PROBE_TRACKER | Uncore cycles Global Queue peer probe tracker is full. The peer probe tracker queue tracks snoops from the IOH and remote sockets. | |
| 01H | 01H | UNC_GQ_CYCLES_NOT_EMPTY.READ_TRACKER | Uncore cycles were Global Queue read tracker has at least one valid entry. | |
| 01H | 02H | UNC_GQ_CYCLES_NOT_EMPTY.WRITE_TRACKER | Uncore cycles were Global Queue write tracker has at least one valid entry. | |
| 01H | 04H | UNC_GQ_CYCLES_NOT_EMPTY.PEER_PROBE_TRACKER | Uncore cycles were Global Queue peer probe tracker has at least one valid entry. The peer probe tracker queue tracks IOH and remote socket snoops. | |
| 03H | 01H | UNC_GQ_ALLOC.READ_TRACKER | Counts the number of tread tracker allocate to deallocate entries. The GQ read tracker allocate to deallocate occupancy count is divided by the count to obtain the average read tracker latency. | |
| 03H | 02H | UNC_GQ_ALLOC.RT_L3_MISS | Counts the number GQ read tracker entries for which a full cache line read has missed the L3. The GQ read tracker L3 miss to fill occupancy count is divided by this count to obtain the average cache line read L3 miss latency. The latency represents the time after which the L3 has determined that the cache line has missed. The time between a GQ read tracker allocation and the L3 determining that the cache line has missed is the average L3 hit latency. The total L3 cache line read miss latency is the hit latency + L3 miss latency. | |
| 03H | 04H | UNC_GQ_ALLOC.RT_TO_L3_RESP | Counts the number of GQ read tracker entries that are allocated in the read tracker queue that hit or miss the L3. The GQ read tracker L3 hit occupancy count is divided by this count to obtain the average L3 hit latency. | |
| 03H | 08H | UNC_GQ_ALLOC.RT_TO_RTID_ACQUIRED | Counts the number of GQ read tracker entries that are allocated in the read tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ read tracker L3 miss to RTID acquired occupancy count is divided by this count to obtain the average latency for a read L3 miss to acquire an RTID. | |
| 03H | 10H | UNC_GQ_ALLOC.WT_TO_RTID_ACQUIRED | Counts the number of GQ write tracker entries that are allocated in the write tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ write tracker L3 miss to RTID occupancy count is divided by this count to obtain the average latency for a write L3 miss to acquire an RTID. | |

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 03H | 20H | UNC_GQ_ALLOC.WRITE_TRACKER | Counts the number of GQ write tracker entries that are allocated in the write tracker queue that miss the L3. The GQ write tracker occupancy count is divided by the this count to obtain the average L3 write miss latency. | |
| 03H | 40H | UNC_GQ_ALLOC.PEER_PROBE_TRACKER | Counts the number of GQ peer probe tracker (snoop) entries that are allocated in the peer probe tracker queue that miss the L3. The GQ peer probe occupancy count is divided by this count to obtain the average L3 peer probe miss latency. | |
| 04H | 01H | UNC_GQ_DATA.FROM_QPI | Cycles Global Queue Quickpath Interface input data port is busy importing data from the Quickpath Interface. Each cycle the input port can transfer 8 or 16 bytes of data. | |
| 04H | 02H | UNC_GQ_DATA.FROM_QMC | Cycles Global Queue Quickpath Memory Interface input data port is busy importing data from the Quickpath Memory Interface. Each cycle the input port can transfer 8 or 16 bytes of data. | |
| 04H | 04H | UNC_GQ_DATA.FROM_L3 | Cycles GQ L3 input data port is busy importing data from the Last Level Cache. Each cycle the input port can transfer 32 bytes of data. | |
| 04H | 08H | UNC_GQ_DATA.FROM_CORES_02 | Cycles GQ Core 0 and 2 input data port is busy importing data from processor cores 0 and 2. Each cycle the input port can transfer 32 bytes of data. | |
| 04H | 10H | UNC_GQ_DATA.FROM_CORES_13 | Cycles GQ Core 1 and 3 input data port is busy importing data from processor cores 1 and 3. Each cycle the input port can transfer 32 bytes of data. | |
| 05H | 01H | UNC_GQ_DATA.TO_QPI_QMC | Cycles GQ QPI and QMC output data port is busy sending data to the Quickpath Interface or Quickpath Memory Interface. Each cycle the output port can transfer 32 bytes of data. | |
| 05H | 02H | UNC_GQ_DATA.TO_L3 | Cycles GQ L3 output data port is busy sending data to the Last Level Cache. Each cycle the output port can transfer 32 bytes of data. | |
| 05H | 04H | UNC_GQ_DATA.TO_CORES | Cycles GQ Core output data port is busy sending data to the Cores. Each cycle the output port can transfer 32 bytes of data. | |
| 06H | 01H | UNC_SNP_RESP_TO_LOCAL_HOME.I_STATE | Number of snoop responses to the local home that L3 does not have the referenced cache line. | |
| 06H | 02H | UNC_SNP_RESP_TO_LOCAL_HOME.S_STATE | Number of snoop responses to the local home that L3 has the referenced line cached in the S state. | |
| 06H | 04H | UNC_SNP_RESP_TO_LOCAL_HOME.FWD_S_STATE | Number of responses to code or data read snoops to the local home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the local home in the S state. | |

### Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 06H | 08H | UNC_SNP_RESP_TO_LOCAL_HOME.FWD_I_STATE | Number of responses to read invalidate snoops to the local home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the local home in the M state. | |
| 06H | 10H | UNC_SNP_RESP_TO_LOCAL_HOME.CONFLICT | Number of conflict snoop responses sent to the local home. | |
| 06H | 20H | UNC_SNP_RESP_TO_LOCAL_HOME.WB | Number of responses to code or data read snoops to the local home that the L3 has the referenced line cached in the M state. | |
| 07H | 01H | UNC_SNP_RESP_TO_REMOTE_HOME.I_STATE | Number of snoop responses to a remote home that L3 does not have the referenced cache line. | |
| 07H | 02H | UNC_SNP_RESP_TO_REMOTE_HOME.S_STATE | Number of snoop responses to a remote home that L3 has the referenced line cached in the S state. | |
| 07H | 04H | UNC_SNP_RESP_TO_REMOTE_HOME.FWD_S_STATE | Number of responses to code or data read snoops to a remote home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the remote home in the S state. | |
| 07H | 08H | UNC_SNP_RESP_TO_REMOTE_HOME.FWD_I_STATE | Number of responses to read invalidate snoops to a remote home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the remote home in the M state. | |
| 07H | 10H | UNC_SNP_RESP_TO_REMOTE_HOME.CONFLICT | Number of conflict snoop responses sent to the local home. | |
| 07H | 20H | UNC_SNP_RESP_TO_REMOTE_HOME.WB | Number of responses to code or data read snoops to a remote home that the L3 has the referenced line cached in the M state. | |
| 07H | 24H | UNC_SNP_RESP_TO_REMOTE_HOME.HITM | Number of HITM snoop responses to a remote home | |
| 08H | 01H | UNC_L3_HITS.READ | Number of code read, data read and RFO requests that hit in the L3 | |
| 08H | 02H | UNC_L3_HITS.WRITE | Number of writeback requests that hit in the L3. Writebacks from the cores will always result in L3 hits due to the inclusive property of the L3. | |
| 08H | 04H | UNC_L3_HITS.PROBE | Number of snoops from IOH or remote sockets that hit in the L3. | |
| 08H | 03H | UNC_L3_HITS.ANY | Number of reads and writes that hit the L3. | |
| 09H | 01H | UNC_L3_MISS.READ | Number of code read, data read and RFO requests that miss the L3. | |
| 09H | 02H | UNC_L3_MISS.WRITE | Number of writeback requests that miss the L3. Should always be zero as writebacks from the cores will always result in L3 hits due to the inclusive property of the L3. | |
| 09H | 04H | UNC_L3_MISS.PROBE | Number of snoops from IOH or remote sockets that miss the L3. | |
| 09H | 03H | UNC_L3_MISS.ANY | Number of reads and writes that miss the L3. | |

### Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 0AH | 01H | UNC_L3_LINES_IN.M_STATE | Counts the number of L3 lines allocated in M state. The only time a cache line is allocated in the M state is when the line was forwarded in M state is forwarded due to a Snoop Read Invalidate Own request. | |
| 0AH | 02H | UNC_L3_LINES_IN.E_STATE | Counts the number of L3 lines allocated in E state. | |
| 0AH | 04H | UNC_L3_LINES_IN.S_STATE | Counts the number of L3 lines allocated in S state. | |
| 0AH | 08H | UNC_L3_LINES_IN.F_STATE | Counts the number of L3 lines allocated in F state. | |
| 0AH | 0FH | UNC_L3_LINES_IN.ANY | Counts the number of L3 lines allocated in any state. | |
| 0BH | 01H | UNC_L3_LINES_OUT.M_STATE | Counts the number of L3 lines victimized that were in the M state. When the victim cache line is in M state, the line is written to its home cache agent which can be either local or remote. | |
| 0BH | 02H | UNC_L3_LINES_OUT.E_STATE | Counts the number of L3 lines victimized that were in the E state. | |
| 0BH | 04H | UNC_L3_LINES_OUT.S_STATE | Counts the number of L3 lines victimized that were in the S state. | |
| 0BH | 08H | UNC_L3_LINES_OUT.I_STATE | Counts the number of L3 lines victimized that were in the I state. | |
| 0BH | 10H | UNC_L3_LINES_OUT.F_STATE | Counts the number of L3 lines victimized that were in the F state. | |
| 0BH | 1FH | UNC_L3_LINES_OUT.ANY | Counts the number of L3 lines victimized in any state. | |
| 20H | 01H | UNC_QHL_REQUESTS.IOH_READS | Counts number of Quickpath Home Logic read requests from the IOH. | |
| 20H | 02H | UNC_QHL_REQUESTS.IOH_WRITES | Counts number of Quickpath Home Logic write requests from the IOH. | |
| 20H | 04H | UNC_QHL_REQUESTS.REMOTE_READS | Counts number of Quickpath Home Logic read requests from a remote socket. | |
| 20H | 08H | UNC_QHL_REQUESTS.REMOTE_WRITES | Counts number of Quickpath Home Logic write requests from a remote socket. | |
| 20H | 10H | UNC_QHL_REQUESTS.LOCAL_READS | Counts number of Quickpath Home Logic read requests from the local socket. | |
| 20H | 20H | UNC_QHL_REQUESTS.LOCAL_WRITES | Counts number of Quickpath Home Logic write requests from the local socket. | |
| 21H | 01H | UNC_QHL_CYCLES_FULL.IOH | Counts uclk cycles all entries in the Quickpath Home Logic IOH are full. | |
| 21H | 02H | UNC_QHL_CYCLES_FULL.REMOTE | Counts uclk cycles all entries in the Quickpath Home Logic remote tracker are full. | |
| 21H | 04H | UNC_QHL_CYCLES_FULL.LOCAL | Counts uclk cycles all entries in the Quickpath Home Logic local tracker are full. | |
| 22H | 01H | UNC_QHL_CYCLES_NOT_EMPTY.IOH | Counts uclk cycles all entries in the Quickpath Home Logic IOH is busy. | |
| 22H | 02H | UNC_QHL_CYCLES_NOT_EMPTY.REMOTE | Counts uclk cycles all entries in the Quickpath Home Logic remote tracker is busy. | |
| 22H | 04H | UNC_QHL_CYCLES_NOT_EMPTY.LOCAL | Counts uclk cycles all entries in the Quickpath Home Logic local tracker is busy. | |

### Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 23H | 01H | UNC_QHL_OCCUPANCY.IOH | QHL IOH tracker allocate to deallocate read occupancy. | |
| 23H | 02H | UNC_QHL_OCCUPANCY.REMOTE | QHL remote tracker allocate to deallocate read occupancy. | |
| 23H | 04H | UNC_QHL_OCCUPANCY.LOCAL | QHL local tracker allocate to deallocate read occupancy. | |
| 24H | 02H | UNC_QHL_ADDRESS_CONFLICTS.2WAY | Counts number of QHL Active Address Table (AAT) entries that saw a max of 2 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates. | |
| 24H | 04H | UNC_QHL_ADDRESS_CONFLICTS.3WAY | Counts number of QHL Active Address Table (AAT) entries that saw a max of 3 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates. | |
| 25H | 01H | UNC_QHL_CONFLICT_CYCLES.IOH | Counts cycles the Quickpath Home Logic IOH Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict. | |
| 25H | 02H | UNC_QHL_CONFLICT_CYCLES.REMOTE | Counts cycles the Quickpath Home Logic Remote Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict. | |
| 25H | 04H | UNC_QHL_CONFLICT_CYCLES.LOCAL | Counts cycles the Quickpath Home Logic Local Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict. | |
| 26H | 01H | UNC_QHL_TO_QMC_BYPASS | Counts number or requests to the Quickpath Memory Controller that bypass the Quickpath Home Logic. All local accesses can be bypassed. For remote requests, only read requests can be bypassed. | |
| 27H | 01H | UNC_QMC_NORMAL_FULL.READ.CH0 | Uncore cycles all the entries in the DRAM channel 0 medium or low priority queue are occupied with read requests. | |
| 27H | 02H | UNC_QMC_NORMAL_FULL.READ.CH1 | Uncore cycles all the entries in the DRAM channel 1 medium or low priority queue are occupied with read requests. | |
| 27H | 04H | UNC_QMC_NORMAL_FULL.READ.CH2 | Uncore cycles all the entries in the DRAM channel 2 medium or low priority queue are occupied with read requests. | |
| 27H | 08H | UNC_QMC_NORMAL_FULL.WRITE.CH0 | Uncore cycles all the entries in the DRAM channel 0 medium or low priority queue are occupied with write requests. | |
| 27H | 10H | UNC_QMC_NORMAL_FULL.WRITE.CH1 | Counts cycles all the entries in the DRAM channel 1 medium or low priority queue are occupied with write requests. | |
| 27H | 20H | UNC_QMC_NORMAL_FULL.WRITE.CH2 | Uncore cycles all the entries in the DRAM channel 2 medium or low priority queue are occupied with write requests. | |

## Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 28H | 01H | UNC_QMC_ISOC_FULL.READ.CH0 | Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous read requests. | |
| 28H | 02H | UNC_QMC_ISOC_FULL.READ.CH1 | Counts cycles all the entries in the DRAM channel 1high priority queue are occupied with isochronous read requests. | |
| 28H | 04H | UNC_QMC_ISOC_FULL.READ.CH2 | Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous read requests. | |
| 28H | 08H | UNC_QMC_ISOC_FULL.WRITE.CH0 | Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous write requests. | |
| 28H | 10H | UNC_QMC_ISOC_FULL.WRITE.CH1 | Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous write requests. | |
| 28H | 20H | UNC_QMC_ISOC_FULL.WRITE.CH2 | Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous write requests. | |
| 29H | 01H | UNC_QMC_BUSY.READ.CH0 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 0. | |
| 29H | 02H | UNC_QMC_BUSY.READ.CH1 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 1. | |
| 29H | 04H | UNC_QMC_BUSY.READ.CH2 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 2. | |
| 29H | 08H | UNC_QMC_BUSY.WRITE.CH0 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 0. | |
| 29H | 10H | UNC_QMC_BUSY.WRITE.CH1 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 1. | |
| 29H | 20H | UNC_QMC_BUSY.WRITE.CH2 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 2. | |
| 2AH | 01H | UNC_QMC_OCCUPANCY.CH0 | IMC channel 0 normal read request occupancy. | |
| 2AH | 02H | UNC_QMC_OCCUPANCY.CH1 | IMC channel 1 normal read request occupancy. | |
| 2AH | 04H | UNC_QMC_OCCUPANCY.CH2 | IMC channel 2 normal read request occupancy. | |
| 2BH | 01H | UNC_QMC_ISSOC_OCCUPANCY.CH0 | IMC channel 0 issoc read request occupancy. | |
| 2BH | 02H | UNC_QMC_ISSOC_OCCUPANCY.CH1 | IMC channel 1 issoc read request occupancy. | |
| 2BH | 04H | UNC_QMC_ISSOC_OCCUPANCY.CH2 | IMC channel 2 issoc read request occupancy. | |
| 2BH | 07H | UNC_QMC_ISSOC_READS.ANY | IMC issoc read request occupancy. | |

## Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 2CH | 01H | UNC_QMC_NORMAL_READS.CH0 | Counts the number of Quickpath Memory Controller channel 0 medium and low priority read requests. The QMC channel 0 normal read occupancy divided by this count provides the average QMC channel 0 read latency. | |
| 2CH | 02H | UNC_QMC_NORMAL_READS.CH1 | Counts the number of Quickpath Memory Controller channel 1 medium and low priority read requests. The QMC channel 1 normal read occupancy divided by this count provides the average QMC channel 1 read latency. | |
| 2CH | 04H | UNC_QMC_NORMAL_READS.CH2 | Counts the number of Quickpath Memory Controller channel 2 medium and low priority read requests. The QMC channel 2 normal read occupancy divided by this count provides the average QMC channel 2 read latency. | |
| 2CH | 07H | UNC_QMC_NORMAL_READS.ANY | Counts the number of Quickpath Memory Controller medium and low priority read requests. The QMC normal read occupancy divided by this count provides the average QMC read latency. | |
| 2DH | 01H | UNC_QMC_HIGH_PRIORITY_READS.CH0 | Counts the number of Quickpath Memory Controller channel 0 high priority isochronous read requests. | |
| 2DH | 02H | UNC_QMC_HIGH_PRIORITY_READS.CH1 | Counts the number of Quickpath Memory Controller channel 1 high priority isochronous read requests. | |
| 2DH | 04H | UNC_QMC_HIGH_PRIORITY_READS.CH2 | Counts the number of Quickpath Memory Controller channel 2 high priority isochronous read requests. | |
| 2DH | 07H | UNC_QMC_HIGH_PRIORITY_READS.ANY | Counts the number of Quickpath Memory Controller high priority isochronous read requests. | |
| 2EH | 01H | UNC_QMC_CRITICAL_PRIORITY_READS.CH0 | Counts the number of Quickpath Memory Controller channel 0 critical priority isochronous read requests. | |
| 2EH | 02H | UNC_QMC_CRITICAL_PRIORITY_READS.CH1 | Counts the number of Quickpath Memory Controller channel 1 critical priority isochronous read requests. | |
| 2EH | 04H | UNC_QMC_CRITICAL_PRIORITY_READS.CH2 | Counts the number of Quickpath Memory Controller channel 2 critical priority isochronous read requests. | |
| 2EH | 07H | UNC_QMC_CRITICAL_PRIORITY_READS.ANY | Counts the number of Quickpath Memory Controller critical priority isochronous read requests. | |
| 2FH | 01H | UNC_QMC_WRITES.FULL.CH0 | Counts number of full cache line writes to DRAM channel 0. | |
| 2FH | 02H | UNC_QMC_WRITES.FULL.CH1 | Counts number of full cache line writes to DRAM channel 1. | |
| 2FH | 04H | UNC_QMC_WRITES.FULL.CH2 | Counts number of full cache line writes to DRAM channel 2. | |
| 2FH | 07H | UNC_QMC_WRITES.FULL.ANY | Counts number of full cache line writes to DRAM. | |
| 2FH | 08H | UNC_QMC_WRITES.PARTIAL.CH0 | Counts number of partial cache line writes to DRAM channel 0. | |
| 2FH | 10H | UNC_QMC_WRITES.PARTIAL.CH1 | Counts number of partial cache line writes to DRAM channel 1. | |

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 2FH | 20H | UNC_QMC_WRITES.PARTIAL.CH2 | Counts number of partial cache line writes to DRAM channel 2. | |
| 2FH | 38H | UNC_QMC_WRITES.PARTIAL.ANY | Counts number of partial cache line writes to DRAM. | |
| 30H | 01H | UNC_QMC_CANCEL.CH0 | Counts number of DRAM channel 0 cancel requests. | |
| 30H | 02H | UNC_QMC_CANCEL.CH1 | Counts number of DRAM channel 1 cancel requests. | |
| 30H | 04H | UNC_QMC_CANCEL.CH2 | Counts number of DRAM channel 2 cancel requests. | |
| 30H | 07H | UNC_QMC_CANCEL.ANY | Counts number of DRAM cancel requests. | |
| 31H | 01H | UNC_QMC_PRIORITY_UPDATES.CH0 | Counts number of DRAM channel 0 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. | |
| 31H | 02H | UNC_QMC_PRIORITY_UPDATES.CH1 | Counts number of DRAM channel 1 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. | |
| 31H | 04H | UNC_QMC_PRIORITY_UPDATES.CH2 | Counts number of DRAM channel 2 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. | |
| 31H | 07H | UNC_QMC_PRIORITY_UPDATES.ANY | Counts number of DRAM priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. | |
| 33H | 04H | UNC_QHL_FRC_ACK_CNFLTS.LOCAL | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the local home. | |
| 40H | 01H | UNC_QPI_TX_STALLED_SINGLE_FLIT.HOME.LINK_0 | Counts cycles the Quickpath outbound link 0 HOME virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 02H | UNC_QPI_TX_STALLED_SINGLE_FLIT.SNOOP.LINK_0 | Counts cycles the Quickpath outbound link 0 SNOOP virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 40H | 04H | UNC_QPI_TX_STALLED_SINGLE_FLIT.NDR.LINK_0 | Counts cycles the Quickpath outbound link 0 non-data response virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 08H | UNC_QPI_TX_STALLED_SINGLE_FLIT.HOME.LINK_1 | Counts cycles the Quickpath outbound link 1 HOME virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 10H | UNC_QPI_TX_STALLED_SINGLE_FLIT.SNOOP.LINK_1 | Counts cycles the Quickpath outbound link 1 SNOOP virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 20H | UNC_QPI_TX_STALLED_SINGLE_FLIT.NDR.LINK_1 | Counts cycles the Quickpath outbound link 1 non-data response virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 07H | UNC_QPI_TX_STALLED_SINGLE_FLIT.LINK_0 | Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 38H | UNC_QPI_TX_STALLED_SINGLE_FLIT.LINK_1 | Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 01H | UNC_QPI_TX_STALLED_MULTI_FLIT.DRS.LINK_0 | Counts cycles the Quickpath outbound link 0 Data ResponSe virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 02H | UNC_QPI_TX_STALLED_MULTI_FLIT.NCB.LINK_0 | Counts cycles the Quickpath outbound link 0 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 04H | UNC_QPI_TX_STALLED_MULTI_FLIT.NCS.LINK_0 | Counts cycles the Quickpath outbound link 0 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 41H | 08H | UNC_QPI_TX_STALLED_MULTI_FLIT.DRS.LINK_1 | Counts cycles the Quickpath outbound link 1 Data ResponSe virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 10H | UNC_QPI_TX_STALLED_MULTI_FLIT.NCB.LINK_1 | Counts cycles the Quickpath outbound link 1 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 20H | UNC_QPI_TX_STALLED_MULTI_FLIT.NCS.LINK_1 | Counts cycles the Quickpath outbound link 1 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 07H | UNC_QPI_TX_STALLED_MULTI_FLIT.LINK_0 | Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 38H | UNC_QPI_TX_STALLED_MULTI_FLIT.LINK_1 | Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 42H | 02H | UNC_QPI_TX_HEADER.BUSY.LINK_0 | Number of cycles that the header buffer in the Quickpath Interface outbound link 0 is busy. | |
| 42H | 08H | UNC_QPI_TX_HEADER.BUSY.LINK_1 | Number of cycles that the header buffer in the Quickpath Interface outbound link 1 is busy. | |
| 43H | 01H | UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_0 | Number of cycles that snoop packets incoming to the Quickpath Interface link 0 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries. | |
| 43H | 02H | UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_1 | Number of cycles that snoop packets incoming to the Quickpath Interface link 1 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries. | |
| 60H | 01H | UNC_DRAM_OPEN.CH0 | Counts number of DRAM Channel 0 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened. | |
| 60H | 02H | UNC_DRAM_OPEN.CH1 | Counts number of DRAM Channel 1 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened. | |
| 60H | 04H | UNC_DRAM_OPEN.CH2 | Counts number of DRAM Channel 2 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened. | |

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 61H | 01H | UNC_DRAM_PAGE_CLOSE.CH0 | DRAM channel 0 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge. | |
| 61H | 02H | UNC_DRAM_PAGE_CLOSE.CH1 | DRAM channel 1 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge. | |
| 61H | 04H | UNC_DRAM_PAGE_CLOSE.CH2 | DRAM channel 2 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge. | |
| 62H | 01H | UNC_DRAM_PAGE_MISS.CH0 | Counts the number of precharges (PRE) that were issued to DRAM channel 0 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. | |
| 62H | 02H | UNC_DRAM_PAGE_MISS.CH1 | Counts the number of precharges (PRE) that were issued to DRAM channel 1 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. | |
| 62H | 04H | UNC_DRAM_PAGE_MISS.CH2 | Counts the number of precharges (PRE) that were issued to DRAM channel 2 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. | |
| 63H | 01H | UNC_DRAM_READ_CAS.CH0 | Counts the number of times a read CAS command was issued on DRAM channel 0. | |
| 63H | 02H | UNC_DRAM_READ_CAS.AUTO PRE_CH0 | Counts the number of times a read CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode. | |
| 63H | 04H | UNC_DRAM_READ_CAS.CH1 | Counts the number of times a read CAS command was issued on DRAM channel 1. | |
| 63H | 08H | UNC_DRAM_READ_CAS.AUTO PRE_CH1 | Counts the number of times a read CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode. | |
| 63H | 10H | UNC_DRAM_READ_CAS.CH2 | Counts the number of times a read CAS command was issued on DRAM channel 2. | |
| 63H | 20H | UNC_DRAM_READ_CAS.AUTO PRE_CH2 | Counts the number of times a read CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode. | |
| 64H | 01H | UNC_DRAM_WRITE_CAS.CH0 | Counts the number of times a write CAS command was issued on DRAM channel 0. | |

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 64H | 02H | UNC_DRAM_WRITE_CAS.AUTO PRE_CH0 | Counts the number of times a write CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode. | |
| 64H | 04H | UNC_DRAM_WRITE_CAS.CH1 | Counts the number of times a write CAS command was issued on DRAM channel 1. | |
| 64H | 08H | UNC_DRAM_WRITE_CAS.AUTO PRE_CH1 | Counts the number of times a write CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode. | |
| 64H | 10H | UNC_DRAM_WRITE_CAS.CH2 | Counts the number of times a write CAS command was issued on DRAM channel 2. | |
| 64H | 20H | UNC_DRAM_WRITE_CAS.AUTO PRE_CH2 | Counts the number of times a write CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode. | |
| 65H | 01H | UNC_DRAM_REFRESH.CH0 | Counts number of DRAM channel 0 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically. | |
| 65H | 02H | UNC_DRAM_REFRESH.CH1 | Counts number of DRAM channel 1 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically. | |
| 65H | 04H | UNC_DRAM_REFRESH.CH2 | Counts number of DRAM channel 2 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically. | |
| 66H | 01H | UNC_DRAM_PRE_ALL.CH0 | Counts number of DRAM Channel 0 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. | |
| 66H | 02H | UNC_DRAM_PRE_ALL.CH1 | Counts number of DRAM Channel 1 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. | |
| 66H | 04H | UNC_DRAM_PRE_ALL.CH2 | Counts number of DRAM Channel 2 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. | |

Intel Xeon processors with CPUID signature of DisplayFamily_DisplayModel 06_2EH have a distinct uncore sub-system that is significantly different from the uncore found in processors with CPUID signature 06_1AH, 06_1EH, and 06_1FH. Non-architectural Performance monitoring events for its uncore will be available in future documentation.

## 19.7 PERFORMANCE MONITORING EVENTS FOR PROCESSORS BASED ON INTEL® MICROARCHITECTURE CODE NAME WESTMERE

Intel 64 processors based on Intel® microarchitecture code name Westmere support the architectural and non-architectural performance-monitoring events listed in Table 19-1 and Table 19-15. Table 19-15 applies to processors with CPUID signature of DisplayFamily_DisplayModel encoding with the following values: 06_25H, 06_2CH. In addition, these processors (CPUID signature of DisplayFamily_DisplayModel 06_25H, 06_2CH) also support the following non-architectural, product-specific uncore performance-monitoring events listed in Table 19-16. Fixed counters support the architecture events defined in Table 19-18.

**Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 03H | 02H | LOAD_BLOCK.OVERLAP_STORE | Loads that partially overlap an earlier store. | |
| 04H | 07H | SB_DRAIN.ANY | All Store buffer stall cycles. | |
| 05H | 02H | MISALIGN_MEMORY.STORE | All store referenced with misaligned address. | |
| 06H | 04H | STORE_BLOCKS.AT_RET | Counts number of loads delayed with at-Retirement block code. The following loads need to be executed at retirement and wait for all senior stores on the same thread to be drained: load splitting across 4K boundary (page split), load accessing uncacheable (UC or USWC) memory, load lock, and load with page table in UC or USWC memory region. | |
| 06H | 08H | STORE_BLOCKS.L1D_BLOCK | Cacheable loads delayed with L1D block code. | |
| 07H | 01H | PARTIAL_ADDRESS_ALIAS | Counts false dependency due to partial address aliasing. | |
| 08H | 01H | DTLB_LOAD_MISSES.ANY | Counts all load misses that cause a page walk. | |
| 08H | 02H | DTLB_LOAD_MISSES.WALK_COMPLETED | Counts number of completed page walks due to load miss in the STLB. | |
| 08H | 04H | DTLB_LOAD_MISSES.WALK_CYCLES | Cycles PMH is busy with a page walk due to a load miss in the STLB. | |
| 08H | 10H | DTLB_LOAD_MISSES.STLB_HIT | Number of cache load STLB hits. | |
| 08H | 20H | DTLB_LOAD_MISSES.PDE_MISS | Number of DTLB cache load misses where the low part of the linear to physical address translation was missed. | |
| 0BH | 01H | MEM_INST_RETIRED.LOADS | Counts the number of instructions with an architecturally-visible load retired on the architected path. | |
| 0BH | 02H | MEM_INST_RETIRED.STORES | Counts the number of instructions with an architecturally-visible store retired on the architected path. | |
| 0BH | 10H | MEM_INST_RETIRED.LATENCY_ABOVE_THRESHOLD | Counts the number of instructions exceeding the latency specified with ld_lat facility. | In conjunction with ld_lat facility |
| 0CH | 01H | MEM_STORE_RETIRED.DTLB_MISS | The event counts the number of retired stores that missed the DTLB. The DTLB miss is not counted if the store operation causes a fault. Does not counter prefetches. Counts both primary and secondary misses to the TLB. | |

### Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 0EH | 01H | UOPS_ISSUED.ANY | Counts the number of Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end. | |
| 0EH | 01H | UOPS_ISSUED.STALLED_CYCLES | Counts the number of cycles no Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end. | set "invert=1, cmask = 1" |
| 0EH | 02H | UOPS_ISSUED.FUSED | Counts the number of fused Uops that were issued from the Register Allocation Table to the Reservation Station. | |
| 0FH | 01H | MEM_UNCORE_RETIRED.UNKNOWN_SOURCE | Load instructions retired with unknown LLC miss (Precise Event). | Applicable to one and two sockets |
| 0FH | 02H | MEM_UNCORE_RETIRED.OHTER_CORE_L2_HIT | Load instructions retired that HIT modified data in sibling core (Precise Event). | Applicable to one and two sockets |
| 0FH | 04H | MEM_UNCORE_RETIRED.REMOTE_HITM | Load instructions retired that HIT modified data in remote socket (Precise Event). | Applicable to two sockets only |
| 0FH | 08H | MEM_UNCORE_RETIRED.LOCAL_DRAM_AND_REMOTE_CACHE_HIT | Load instructions retired local dram and remote cache HIT data sources (Precise Event). | Applicable to one and two sockets |
| 0FH | 10H | MEM_UNCORE_RETIRED.REMOTE_DRAM | Load instructions retired remote DRAM and remote home-remote cache HITM (Precise Event). | Applicable to two sockets only |
| 0FH | 20H | MEM_UNCORE_RETIRED.OTHER_LLC_MISS | Load instructions retired other LLC miss (Precise Event). | Applicable to two sockets only |
| 0FH | 80H | MEM_UNCORE_RETIRED.UNCACHEABLE | Load instructions retired I/O (Precise Event). | Applicable to one and two sockets |
| 10H | 01H | FP_COMP_OPS_EXE.X87 | Counts the number of FP Computational Uops Executed. The number of FADD, FSUB, FCOM, FMULs, integer MULsand IMULs, FDIVs, FPREMs, FSQRTS, integer DIVs, and IDIVs. This event does not distinguish an FADD used in the middle of a transcendental flow from a separate FADD instruction. | |
| 10H | 02H | FP_COMP_OPS_EXE.MMX | Counts number of MMX Uops executed. | |
| 10H | 04H | FP_COMP_OPS_EXE.SSE_FP | Counts number of SSE and SSE2 FP uops executed. | |
| 10H | 08H | FP_COMP_OPS_EXE.SSE2_INTEGER | Counts number of SSE2 integer uops executed. | |
| 10H | 10H | FP_COMP_OPS_EXE.SSE_FP_PACKED | Counts number of SSE FP packed uops executed. | |
| 10H | 20H | FP_COMP_OPS_EXE.SSE_FP_SCALAR | Counts number of SSE FP scalar uops executed. | |
| 10H | 40H | FP_COMP_OPS_EXE.SSE_SINGLE_PRECISION | Counts number of SSE* FP single precision uops executed. | |
| 10H | 80H | FP_COMP_OPS_EXE.SSE_DOUBLE_PRECISION | Counts number of SSE* FP double precision uops executed. | |
| 12H | 01H | SIMD_INT_128.PACKED_MPY | Counts number of 128 bit SIMD integer multiply operations. | |

### Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 12H | 02H | SIMD_INT_128.PACKED_SHIFT | Counts number of 128 bit SIMD integer shift operations. | |
| 12H | 04H | SIMD_INT_128.PACK | Counts number of 128 bit SIMD integer pack operations. | |
| 12H | 08H | SIMD_INT_128.UNPACK | Counts number of 128 bit SIMD integer unpack operations. | |
| 12H | 10H | SIMD_INT_128.PACKED_LOGICAL | Counts number of 128 bit SIMD integer logical operations. | |
| 12H | 20H | SIMD_INT_128.PACKED_ARITH | Counts number of 128 bit SIMD integer arithmetic operations. | |
| 12H | 40H | SIMD_INT_128.SHUFFLE_MOVE | Counts number of 128 bit SIMD integer shuffle and move operations. | |
| 13H | 01H | LOAD_DISPATCH.RS | Counts number of loads dispatched from the Reservation Station that bypass the Memory Order Buffer. | |
| 13H | 02H | LOAD_DISPATCH.RS_DELAYED | Counts the number of delayed RS dispatches at the stage latch. If an RS dispatch can not bypass to LB, it has another chance to dispatch from the one-cycle delayed staging latch before it is written into the LB. | |
| 13H | 04H | LOAD_DISPATCH.MOB | Counts the number of loads dispatched from the Reservation Station to the Memory Order Buffer. | |
| 13H | 07H | LOAD_DISPATCH.ANY | Counts all loads dispatched from the Reservation Station. | |
| 14H | 01H | ARITH.CYCLES_DIV_BUSY | Counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE.<br>Set 'edge =1, invert=1, cmask=1' to count the number of divides. | Count may be incorrect When SMT is on |
| 14H | 02H | ARITH.MUL | Counts the number of multiply operations executed. This includes integer as well as floating point multiply operations but excludes DPPS mul and MPSAD. | Count may be incorrect When SMT is on |
| 17H | 01H | INST_QUEUE_WRITES | Counts the number of instructions written into the instruction queue every cycle. | |
| 18H | 01H | INST_DECODED.DEC0 | Counts number of instructions that require decoder 0 to be decoded. Usually, this means that the instruction maps to more than 1 uop. | |
| 19H | 01H | TWO_UOP_INSTS_DECODED | An instruction that generates two uops was decoded. | |

**Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 1EH | 01H | INST_QUEUE_WRITE_CYCLES | This event counts the number of cycles during which instructions are written to the instruction queue. Dividing this counter by the number of instructions written to the instruction queue (INST_QUEUE_WRITES) yields the average number of instructions decoded each cycle. If this number is less than four and the pipe stalls, this indicates that the decoder is failing to decode enough instructions per cycle to sustain the 4-wide pipeline. | If SSE* instructions that are 6 bytes or longer arrive one after another, then front end throughput may limit execution speed. |
| 20H | 01H | LSD_OVERFLOW | Number of loops that can not stream from the instruction queue. | |
| 24H | 01H | L2_RQSTS.LD_HIT | Counts number of loads that hit the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches. L2 loads can be rejected for various reasons. Only non rejected loads are counted. | |
| 24H | 02H | L2_RQSTS.LD_MISS | Counts the number of loads that miss the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches. | |
| 24H | 03H | L2_RQSTS.LOADS | Counts all L2 load requests. L2 loads include both L1D demand misses as well as L1D prefetches. | |
| 24H | 04H | L2_RQSTS.RFO_HIT | Counts the number of store RFO requests that hit the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches. Count includes WC memory requests, where the data is not fetched but the permission to write the line is required. | |
| 24H | 08H | L2_RQSTS.RFO_MISS | Counts the number of store RFO requests that miss the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches. | |
| 24H | 0CH | L2_RQSTS.RFOS | Counts all L2 store RFO requests. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches.. | |
| 24H | 10H | L2_RQSTS.IFETCH_HIT | Counts number of instruction fetches that hit the L2 cache. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches. | |
| 24H | 20H | L2_RQSTS.IFETCH_MISS | Counts number of instruction fetches that miss the L2 cache. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches. | |
| 24H | 30H | L2_RQSTS.IFETCHES | Counts all instruction fetches. L2 instruction fetches include both L1I demand misses as well as L1I instruction prefetches. | |
| 24H | 40H | L2_RQSTS.PREFETCH_HIT | Counts L2 prefetch hits for both code and data. | |
| 24H | 80H | L2_RQSTS.PREFETCH_MISS | Counts L2 prefetch misses for both code and data. | |
| 24H | C0H | L2_RQSTS.PREFETCHES | Counts all L2 prefetches for both code and data. | |
| 24H | AAH | L2_RQSTS.MISS | Counts all L2 misses for both code and data. | |

## Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 24H | FFH | L2_RQSTS.REFERENCES | Counts all L2 requests for both code and data. | |
| 26H | 01H | L2_DATA_RQSTS.DEMAND.I_STATE | Counts number of L2 data demand loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 02H | L2_DATA_RQSTS.DEMAND.S_STATE | Counts number of L2 data demand loads where the cache line to be loaded is in the S (shared) state. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 04H | L2_DATA_RQSTS.DEMAND.E_STATE | Counts number of L2 data demand loads where the cache line to be loaded is in the E (exclusive) state. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 08H | L2_DATA_RQSTS.DEMAND.M_STATE | Counts number of L2 data demand loads where the cache line to be loaded is in the M (modified) state. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 0FH | L2_DATA_RQSTS.DEMAND.MESI | Counts all L2 data demand requests. L2 demand loads are both L1D demand misses and L1D prefetches. | |
| 26H | 10H | L2_DATA_RQSTS.PREFETCH.I_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. | |
| 26H | 20H | L2_DATA_RQSTS.PREFETCH.S_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the S (shared) state. A prefetch RFO will miss on an S state line, while a prefetch read will hit on an S state line. | |
| 26H | 40H | L2_DATA_RQSTS.PREFETCH.E_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the E (exclusive) state. | |
| 26H | 80H | L2_DATA_RQSTS.PREFETCH.M_STATE | Counts number of L2 prefetch data loads where the cache line to be loaded is in the M (modified) state. | |
| 26H | F0H | L2_DATA_RQSTS.PREFETCH.MESI | Counts all L2 prefetch requests. | |
| 26H | FFH | L2_DATA_RQSTS.ANY | Counts all L2 data requests. | |
| 27H | 01H | L2_WRITE.RFO.I_STATE | Counts number of L2 demand store RFO requests where the cache line to be loaded is in the I (invalid) state, i.e, a cache miss. The L1D prefetcher does not issue a RFO prefetch. | This is a demand RFO request |
| 27H | 02H | L2_WRITE.RFO.S_STATE | Counts number of L2 store RFO requests where the cache line to be loaded is in the S (shared) state. The L1D prefetcher does not issue a RFO prefetch,. | This is a demand RFO request |
| 27H | 08H | L2_WRITE.RFO.M_STATE | Counts number of L2 store RFO requests where the cache line to be loaded is in the M (modified) state. The L1D prefetcher does not issue a RFO prefetch. | This is a demand RFO request |
| 27H | 0EH | L2_WRITE.RFO.HIT | Counts number of L2 store RFO requests where the cache line to be loaded is in either the S, E or M states. The L1D prefetcher does not issue a RFO prefetch. | This is a demand RFO request |

### Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 27H | 0FH | L2_WRITE.RFO.MESI | Counts all L2 store RFO requests.The L1D prefetcher does not issue a RFO prefetch. | This is a demand RFO request |
| 27H | 10H | L2_WRITE.LOCK.I_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. | |
| 27H | 20H | L2_WRITE.LOCK.S_STATE | Counts number of L2 lock RFO requests where the cache line to be loaded is in the S (shared) state. | |
| 27H | 40H | L2_WRITE.LOCK.E_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the E (exclusive) state. | |
| 27H | 80H | L2_WRITE.LOCK.M_STATE | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the M (modified) state. | |
| 27H | E0H | L2_WRITE.LOCK.HIT | Counts number of L2 demand lock RFO requests where the cache line to be loaded is in either the S, E, or M state. | |
| 27H | F0H | L2_WRITE.LOCK.MESI | Counts all L2 demand lock RFO requests. | |
| 28H | 01H | L1D_WB_L2.I_STATE | Counts number of L1 writebacks to the L2 where the cache line to be written is in the I (invalid) state, i.e. a cache miss. | |
| 28H | 02H | L1D_WB_L2.S_STATE | Counts number of L1 writebacks to the L2 where the cache line to be written is in the S state. | |
| 28H | 04H | L1D_WB_L2.E_STATE | Counts number of L1 writebacks to the L2 where the cache line to be written is in the E (exclusive) state. | |
| 28H | 08H | L1D_WB_L2.M_STATE | Counts number of L1 writebacks to the L2 where the cache line to be written is in the M (modified) state. | |
| 28H | 0FH | L1D_WB_L2.MESI | Counts all L1 writebacks to the L2 . | |
| 2EH | 41H | L3_LAT_CACHE.MISS | Counts uncore Last Level Cache misses. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended. | see Table 19-1 |
| 2EH | 4FH | L3_LAT_CACHE.REFERENCE | Counts uncore Last Level Cache references. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended. | see Table 19-1 |
| 3CH | 00H | CPU_CLK_UNHALTED.THREAD_P | Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling. | see Table 19-1 |
| 3CH | 01H | CPU_CLK_UNHALTED.REF_P | Increments at the frequency of TSC when not halted. | see Table 19-1 |
| 49H | 01H | DTLB_MISSES.ANY | Counts the number of misses in the STLB which causes a page walk. | |

## Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 49H | 02H | DTLB_MISSES.WALK_COMPLETED | Counts number of misses in the STLB which resulted in a completed page walk. | |
| 49H | 04H | DTLB_MISSES.WALK_CYCLES | Counts cycles of page walk due to misses in the STLB. | |
| 49H | 10H | DTLB_MISSES.STLB_HIT | Counts the number of DTLB first level misses that hit in the second level TLB. This event is only relevant if the core contains multiple DTLB levels. | |
| 49H | 20H | DTLB_MISSES.PDE_MISS | Number of DTLB misses caused by low part of address, includes references to 2M pages because 2M pages do not use the PDE. | |
| 49H | 80H | DTLB_MISSES.LARGE_WALK_COMPLETED | Counts number of completed large page walks due to misses in the STLB. | |
| 4CH | 01H | LOAD_HIT_PRE | Counts load operations sent to the L1 data cache while a previous SSE prefetch instruction to the same cache line has started prefetching but has not yet finished. | Counter 0, 1 only |
| 4EH | 01H | L1D_PREFETCH.REQUESTS | Counts number of hardware prefetch requests dispatched out of the prefetch FIFO. | Counter 0, 1 only |
| 4EH | 02H | L1D_PREFETCH.MISS | Counts number of hardware prefetch requests that miss the L1D. There are two prefetchers in the L1D. A streamer, which predicts lines sequentially after this one should be fetched, and the IP prefetcher that remembers access patterns for the current instruction. The streamer prefetcher stops on an L1D hit, while the IP prefetcher does not. | Counter 0, 1 only |
| 4EH | 04H | L1D_PREFETCH.TRIGGERS | Counts number of prefetch requests triggered by the Finite State Machine and pushed into the prefetch FIFO. Some of the prefetch requests are dropped due to overwrites or competition between the IP index prefetcher and streamer prefetcher. The prefetch FIFO contains 4 entries. | Counter 0, 1 only |
| 4FH | 10H | EPT.WALK_CYCLES | Counts Extended Page walk cycles. | |
| 51H | 01H | L1D.REPL | Counts the number of lines brought into the L1 data cache. | Counter 0, 1 only |
| 51H | 02H | L1D.M_REPL | Counts the number of modified lines brought into the L1 data cache. | Counter 0, 1 only |
| 51H | 04H | L1D.M_EVICT | Counts the number of modified lines evicted from the L1 data cache due to replacement. | Counter 0, 1 only |
| 51H | 08H | L1D.M_SNOOP_EVICT | Counts the number of modified lines evicted from the L1 data cache due to snoop HITM intervention. | Counter 0, 1 only |
| 52H | 01H | L1D_CACHE_PREFETCH_LOCK_FB_HIT | Counts the number of cacheable load lock speculated instructions accepted into the fill buffer. | |
| 60H | 01H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND.READ_DATA | Counts weighted cycles of offcore demand data read requests. Does not include L2 prefetch requests. | counter 0 |
| 60H | 02H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND.READ_CODE | Counts weighted cycles of offcore demand code read requests. Does not include L2 prefetch requests. | counter 0 |

**Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 60H | 04H | OFFCORE_REQUESTS_OUTSTANDING.DEMAND.RFO | Counts weighted cycles of offcore demand RFO requests. Does not include L2 prefetch requests. | counter 0 |
| 60H | 08H | OFFCORE_REQUESTS_OUTSTANDING.ANY.READ | Counts weighted cycles of offcore read requests of any kind. Include L2 prefetch requests. | counter 0 |
| 63H | 01H | CACHE_LOCK_CYCLES.L1D_L2 | Cycle count during which the L1D and L2 are locked. A lock is asserted when there is a locked memory access, due to uncacheable memory, a locked operation that spans two cache lines, or a page walk from an uncacheable page table. This event does not cause locks, it merely detects them. | Counter 0, 1 only. L1D and L2 locks have a very high performance penalty and it is highly recommended to avoid such accesses. |
| 63H | 02H | CACHE_LOCK_CYCLES.L1D | Counts the number of cycles that cacheline in the L1 data cache unit is locked. | Counter 0, 1 only. |
| 6CH | 01H | IO_TRANSACTIONS | Counts the number of completed I/O transactions. | |
| 80H | 01H | L1I.HITS | Counts all instruction fetches that hit the L1 instruction cache. | |
| 80H | 02H | L1I.MISSES | Counts all instruction fetches that miss the L1I cache. This includes instruction cache misses, streaming buffer misses, victim cache misses and uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding. | |
| 80H | 03H | L1I.READS | Counts all instruction fetches, including uncacheable fetches that bypass the L1I. | |
| 80H | 04H | L1I.CYCLES_STALLED | Cycle counts for which an instruction fetch stalls due to a L1I cache miss, ITLB miss or ITLB fault. | |
| 82H | 01H | LARGE_ITLB.HIT | Counts number of large ITLB hits. | |
| 85H | 01H | ITLB_MISSES.ANY | Counts the number of misses in all levels of the ITLB which causes a page walk. | |
| 85H | 02H | ITLB_MISSES.WALK_COMPLETED | Counts number of misses in all levels of the ITLB which resulted in a completed page walk. | |
| 85H | 04H | ITLB_MISSES.WALK_CYCLES | Counts ITLB miss page walk cycles. | |
| 85H | 10H | ITLB_MISSES.STLB_HIT | Counts number of ITLB first level miss but second level hits | |
| 85H | 80H | ITLB_MISSES.LARGE_WALK_COMPLETED | Counts number of completed large page walks due to misses in the STLB. | |
| 87H | 01H | ILD_STALL.LCP | Cycles Instruction Length Decoder stalls due to length changing prefixes: 66, 67 or REX.W (for EM64T) instructions which change the length of the decoded instruction. | |
| 87H | 02H | ILD_STALL.MRU | Instruction Length Decoder stall cycles due to Brand Prediction Unit (PBU) Most Recently Used (MRU) bypass. | |
| 87H | 04H | ILD_STALL.IQ_FULL | Stall cycles due to a full instruction queue. | |
| 87H | 08H | ILD_STALL.REGEN | Counts the number of regen stalls. | |
| 87H | 0FH | ILD_STALL.ANY | Counts any cycles the Instruction Length Decoder is stalled. | |

## Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 88H | 01H | BR_INST_EXEC.COND | Counts the number of conditional near branch instructions executed, but not necessarily retired. | |
| 88H | 02H | BR_INST_EXEC.DIRECT | Counts all unconditional near branch instructions excluding calls and indirect branches. | |
| 88H | 04H | BR_INST_EXEC.INDIRECT_NON_CALL | Counts the number of executed indirect near branch instructions that are not calls. | |
| 88H | 07H | BR_INST_EXEC.NON_CALLS | Counts all non call near branch instructions executed, but not necessarily retired. | |
| 88H | 08H | BR_INST_EXEC.RETURN_NEAR | Counts indirect near branches that have a return mnemonic. | |
| 88H | 10H | BR_INST_EXEC.DIRECT_NEAR_CALL | Counts unconditional near call branch instructions, excluding non call branch, executed. | |
| 88H | 20H | BR_INST_EXEC.INDIRECT_NEAR_CALL | Counts indirect near calls, including both register and memory indirect, executed. | |
| 88H | 30H | BR_INST_EXEC.NEAR_CALLS | Counts all near call branches executed, but not necessarily retired. | |
| 88H | 40H | BR_INST_EXEC.TAKEN | Counts taken near branches executed, but not necessarily retired. | |
| 88H | 7FH | BR_INST_EXEC.ANY | Counts all near executed branches (not necessarily retired). This includes only instructions and not micro-op branches. Frequent branching is not necessarily a major performance issue. However frequent branch mispredictions may be a problem. | |
| 89H | 01H | BR_MISP_EXEC.COND | Counts the number of mispredicted conditional near branch instructions executed, but not necessarily retired. | |
| 89H | 02H | BR_MISP_EXEC.DIRECT | Counts mispredicted macro unconditional near branch instructions, excluding calls and indirect branches (should always be 0). | |
| 89H | 04H | BR_MISP_EXEC.INDIRECT_NON_CALL | Counts the number of executed mispredicted indirect near branch instructions that are not calls. | |
| 89H | 07H | BR_MISP_EXEC.NON_CALLS | Counts mispredicted non call near branches executed, but not necessarily retired. | |
| 89H | 08H | BR_MISP_EXEC.RETURN_NEAR | Counts mispredicted indirect branches that have a rear return mnemonic. | |
| 89H | 10H | BR_MISP_EXEC.DIRECT_NEAR_CALL | Counts mispredicted non-indirect near calls executed, (should always be 0). | |
| 89H | 20H | BR_MISP_EXEC.INDIRECT_NEAR_CALL | Counts mispredicted indirect near calls exeucted, including both register and memory indirect. | |
| 89H | 30H | BR_MISP_EXEC.NEAR_CALLS | Counts all mispredicted near call branches executed, but not necessarily retired. | |
| 89H | 40H | BR_MISP_EXEC.TAKEN | Counts executed mispredicted near branches that are taken, but not necessarily retired. | |
| 89H | 7FH | BR_MISP_EXEC.ANY | Counts the number of mispredicted near branch instructions that were executed, but not necessarily retired. | |

**Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| A2H | 01H | RESOURCE_STALLS.ANY | Counts the number of Allocator resource related stalls. Includes register renaming buffer entries, memory buffer entries. In addition to resource related stalls, this event counts some other events. Includes stalls arising during branch misprediction recovery, such as if retirement of the mispredicted branch is delayed and stalls arising while store buffer is draining from synchronizing operations. | Does not include stalls due to SuperQ (off core) queue full, too many cache misses, etc. |
| A2H | 02H | RESOURCE_STALLS.LOAD | Counts the cycles of stall due to lack of load buffer for load operation. | |
| A2H | 04H | RESOURCE_STALLS.RS_FULL | This event counts the number of cycles when the number of instructions in the pipeline waiting for execution reaches the limit the processor can handle. A high count of this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, or instructions dependent upon instructions further down the pipeline that have yet to retire. | When RS is full, new instructions can not enter the reservation station and start execution. |
| A2H | 08H | RESOURCE_STALLS.STORE | This event counts the number of cycles that a resource related stall will occur due to the number of store instructions reaching the limit of the pipeline, (i.e. all store buffers are used). The stall ends when a store instruction commits its data to the cache or memory. | |
| A2H | 10H | RESOURCE_STALLS.ROB_FULL | Counts the cycles of stall due to re-order buffer full. | |
| A2H | 20H | RESOURCE_STALLS.FPCW | Counts the number of cycles while execution was stalled due to writing the floating-point unit (FPU) control word. | |
| A2H | 40H | RESOURCE_STALLS.MXCSR | Stalls due to the MXCSR register rename occurring to close to a previous MXCSR rename. The MXCSR provides control and status for the MMX registers. | |
| A2H | 80H | RESOURCE_STALLS.OTHER | Counts the number of cycles while execution was stalled due to other resource issues. | |
| A6H | 01H | MACRO_INSTS.FUSIONS_DECODED | Counts the number of instructions decoded that are macro-fused but not necessarily executed or retired. | |
| A7H | 01H | BACLEAR_FORCE_IQ | Counts number of times a BACLEAR was forced by the Instruction Queue. The IQ is also responsible for providing conditional branch prediciton direction based on a static scheme and dynamic data provided by the L2 Branch Prediction Unit. If the conditional branch target is not found in the Target Array and the IQ predicts that the branch is taken, then the IQ will force the Branch Address Calculator to issue a BACLEAR. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. | |
| A8H | 01H | LSD.UOPS | Counts the number of micro-ops delivered by loop stream detector. | Use cmask=1 and invert to count cycles |
| AEH | 01H | ITLB_FLUSH | Counts the number of ITLB flushes. | |

## Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| B0H | 01H | OFFCORE_REQUESTS.DEMAND.READ_DATA | Counts number of offcore demand data read requests. Does not count L2 prefetch requests. | |
| B0H | 02H | OFFCORE_REQUESTS.DEMAND.READ_CODE | Counts number of offcore demand code read requests. Does not count L2 prefetch requests. | |
| B0H | 04H | OFFCORE_REQUESTS.DEMAND.RFO | Counts number of offcore demand RFO requests. Does not count L2 prefetch requests. | |
| B0H | 08H | OFFCORE_REQUESTS.ANY.READ | Counts number of offcore read requests. Includes L2 prefetch requests. | |
| B0H | 10H | OFFCORE_REQUESTS.ANY.RFO | Counts number of offcore RFO requests. Includes L2 prefetch requests. | |
| B0H | 40H | OFFCORE_REQUESTS.L1D_WRITEBACK | Counts number of L1D writebacks to the uncore. | |
| B0H | 80H | OFFCORE_REQUESTS.ANY | Counts all offcore requests. | |
| B1H | 01H | UOPS_EXECUTED.PORT0 | Counts number of Uops executed that were issued on port 0. Port 0 handles integer arithmetic, SIMD and FP add Uops. | |
| B1H | 02H | UOPS_EXECUTED.PORT1 | Counts number of Uops executed that were issued on port 1. Port 1 handles integer arithmetic, SIMD, integer shift, FP multiply and FP divide Uops. | |
| B1H | 04H | UOPS_EXECUTED.PORT2_CORE | Counts number of Uops executed that were issued on port 2. Port 2 handles the load Uops. This is a core count only and can not be collected per thread. | |
| B1H | 08H | UOPS_EXECUTED.PORT3_CORE | Counts number of Uops executed that were issued on port 3. Port 3 handles store Uops. This is a core count only and can not be collected per thread. | |
| B1H | 10H | UOPS_EXECUTED.PORT4_CORE | Counts number of Uops executed that where issued on port 4. Port 4 handles the value to be stored for the store Uops issued on port 3. This is a core count only and can not be collected per thread. | |
| B1H | 1FH | UOPS_EXECUTED.CORE_ACTIVE_CYCLES_NO_PORT5 | Counts number of cycles there are one or more uops being executed and were issued on ports 0-4. This is a core count only and can not be collected per thread. | |
| B1H | 20H | UOPS_EXECUTED.PORT5 | Counts number of Uops executed that where issued on port 5. | |
| B1H | 3FH | UOPS_EXECUTED.CORE_ACTIVE_CYCLES | Counts number of cycles there are one or more uops being executed on any ports. This is a core count only and can not be collected per thread. | |
| B1H | 40H | UOPS_EXECUTED.PORT015 | Counts number of Uops executed that where issued on port 0, 1, or 5. | use cmask=1, invert=1 to count stall cycles |
| B1H | 80H | UOPS_EXECUTED.PORT234 | Counts number of Uops executed that where issued on port 2, 3, or 4. | |
| B2H | 01H | OFFCORE_REQUESTS_SQ_FULL | Counts number of cycles the SQ is full to handle off-core requests. | |
| B3H | 01H | SNOOPQ_REQUESTS_OUTSTANDING.DATA | Counts weighted cycles of snoopq requests for data. Counter 0 only. | Use cmask=1 to count cycles not empty. |

**Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| B3H | 02H | SNOOPQ_REQUESTS_OUTSTANDING.INVALIDATE | Counts weighted cycles of snoopq invalidate requests. Counter 0 only. | Use cmask=1 to count cycles not empty. |
| B3H | 04H | SNOOPQ_REQUESTS_OUTSTANDING.CODE | Counts weighted cycles of snoopq requests for code. Counter 0 only. | Use cmask=1 to count cycles not empty. |
| B4H | 01H | SNOOPQ_REQUESTS.CODE | Counts the number of snoop code requests. | |
| B4H | 02H | SNOOPQ_REQUESTS.DATA | Counts the number of snoop data requests. | |
| B4H | 04H | SNOOPQ_REQUESTS.INVALIDATE | Counts the number of snoop invalidate requests. | |
| B7H | 01H | OFF_CORE_RESPONSE_0 | see Section 18.7.1.3, "Off-core Response Performance Monitoring in the Processor Core" | Requires programming MSR 01A6H |
| B8H | 01H | SNOOP_RESPONSE.HIT | Counts HIT snoop response sent by this thread in response to a snoop request. | |
| B8H | 02H | SNOOP_RESPONSE.HITE | Counts HIT E snoop response sent by this thread in response to a snoop request. | |
| B8H | 04H | SNOOP_RESPONSE.HITM | Counts HIT M snoop response sent by this thread in response to a snoop request. | |
| BBH | 01H | OFF_CORE_RESPONSE_1 | see Section 18.7.1.3, "Off-core Response Performance Monitoring in the Processor Core" | Use MSR 01A7H |
| C0H | 00H | INST_RETIRED.ANY_P | See Table 19-1<br>Notes: INST_RETIRED.ANY is counted by a designated fixed counter. INST_RETIRED.ANY_P is counted by a programmable counter and is an architectural performance event. Event is supported if CPUID.A.EBX[1] = 0. | Counting: Faulting executions of GETSEC/VM entry/VM Exit/MWait will not count as retired instructions. |
| C0H | 02H | INST_RETIRED.X87 | Counts the number of floating point computational operations retired: floating point computational operations executed by the assist handler and sub-operations of complex floating point instructions like transcendental instructions. | |
| C0H | 04H | INST_RETIRED.MMX | Counts the number of retired: MMX instructions. | |
| C2H | 01H | UOPS_RETIRED.ANY | Counts the number of micro-ops retired, (macro-fused=1, micro-fused=2, others=1; maximum count of 8 per cycle). Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. | Use cmask=1 and invert to count active cycles or stalled cycles |
| C2H | 02H | UOPS_RETIRED.RETIRE_SLOTS | Counts the number of retirement slots used each cycle | |
| C2H | 04H | UOPS_RETIRED.MACRO_FUSED | Counts number of macro-fused uops retired. | |
| C3H | 01H | MACHINE_CLEARS.CYCLES | Counts the cycles machine clear is asserted. | |
| C3H | 02H | MACHINE_CLEARS.MEM_ORDER | Counts the number of machine clears due to memory order conflicts. | |

## Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| C3H | 04H | MACHINE_CLEARS.SMC | Counts the number of times that a program writes to a code section. Self-modifying code causes a sever penalty in all Intel 64 and IA-32 processors. The modified cache line is written back to the L2 and L3caches. | |
| C4H | 00H | BR_INST_RETIRED.ALL_BRANCHES | Branch instructions at retirement | See Table 19-1 |
| C4H | 01H | BR_INST_RETIRED.CONDITIONAL | Counts the number of conditional branch instructions retired. | |
| C4H | 02H | BR_INST_RETIRED.NEAR_CALL | Counts the number of direct & indirect near unconditional calls retired. | |
| C5H | 00H | BR_MISP_RETIRED.ALL_BRANCHES | Mispredicted branch instructions at retirement | See Table 19-1 |
| C5H | 01H | BR_MISP_RETIRED.CONDITIONAL | Counts mispredicted conditional retired calls. | |
| C5H | 02H | BR_MISP_RETIRED.NEAR_CALL | Counts mispredicted direct & indirect near unconditional retired calls. | |
| C5H | 04H | BR_MISP_RETIRED.ALL_BRANCHES | Counts all mispredicted retired calls. | |
| C7H | 01H | SSEX_UOPS_RETIRED.PACKED_SINGLE | Counts SIMD packed single-precision floating point Uops retired. | |
| C7H | 02H | SSEX_UOPS_RETIRED.SCALAR_SINGLE | Counts SIMD calar single-precision floating point Uops retired. | |
| C7H | 04H | SSEX_UOPS_RETIRED.PACKED_DOUBLE | Counts SIMD packed double-precision floating point Uops retired. | |
| C7H | 08H | SSEX_UOPS_RETIRED.SCALAR_DOUBLE | Counts SIMD scalar double-precision floating point Uops retired. | |
| C7H | 10H | SSEX_UOPS_RETIRED.VECTOR_INTEGER | Counts 128-bit SIMD vector integer Uops retired. | |
| C8H | 20H | ITLB_MISS_RETIRED | Counts the number of retired instructions that missed the ITLB when the instruction was fetched. | |
| CBH | 01H | MEM_LOAD_RETIRED.L1D_HIT | Counts number of retired loads that hit the L1 data cache. | |
| CBH | 02H | MEM_LOAD_RETIRED.L2_HIT | Counts number of retired loads that hit the L2 data cache. | |
| CBH | 04H | MEM_LOAD_RETIRED.L3_UNSHARED_HIT | Counts number of retired loads that hit their own, unshared lines in the L3 cache. | |
| CBH | 08H | MEM_LOAD_RETIRED.OTHER_CORE_L2_HIT_HITM | Counts number of retired loads that hit in a sibling core's L2 (on die core). Since the L3 is inclusive of all cores on the package, this is an L3 hit. This counts both clean or modified hits. | |
| CBH | 10H | MEM_LOAD_RETIRED.L3_MISS | Counts number of retired loads that miss the L3 cache. The load was satisfied by a remote socket, local memory or an IOH. | |

### Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| CBH | 40H | MEM_LOAD_RETIRED.HIT_LFB | Counts number of retired loads that miss the L1D and the address is located in an allocated line fill buffer and will soon be committed to cache. This is counting secondary L1D misses. | |
| CBH | 80H | MEM_LOAD_RETIRED.DTLB_MISS | Counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault. This event counts loads from cacheable memory only. The event does not count loads by software prefetches. Counts both primary and secondary misses to the TLB. | |
| CCH | 01H | FP_MMX_TRANS.TO_FP | Counts the first floating-point instruction following any MMX instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states. | |
| CCH | 02H | FP_MMX_TRANS.TO_MMX | Counts the first MMX instruction following a floating-point instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states. | |
| CCH | 03H | FP_MMX_TRANS.ANY | Counts all transitions from floating point to MMX instructions and from MMX instructions to floating point instructions. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states. | |
| D0H | 01H | MACRO_INSTS.DECODED | Counts the number of instructions decoded, (but not necessarily executed or retired). | |
| D1H | 01H | UOPS_DECODED.STALL_CYCLES | Counts the cycles of decoder stalls. INV=1, Cmask= 1 | |
| D1H | 02H | UOPS_DECODED.MS | Counts the number of Uops decoded by the Microcode Sequencer, MS. The MS delivers uops when the instruction is more than 4 uops long or a microcode assist is occurring. | |
| D1H | 04H | UOPS_DECODED.ESP_FOLDING | Counts number of stack pointer (ESP) instructions decoded: push , pop , call , ret, etc. ESP instructions do not generate a Uop to increment or decrement ESP. Instead, they update an ESP_Offset register that keeps track of the delta to the current value of the ESP register. | |
| D1H | 08H | UOPS_DECODED.ESP_SYNC | Counts number of stack pointer (ESP) sync operations where an ESP instruction is corrected by adding the ESP offset register to the current value of the ESP register. | |
| D2H | 01H | RAT_STALLS.FLAGS | Counts the number of cycles during which execution stalled due to several reasons, one of which is a partial flag register stall. A partial register stall may occur when two conditions are met: 1) an instruction modifies some, but not all, of the flags in the flag register and 2) the next instruction, which depends on flags, depends on flags that were not modified by this instruction. | |

## Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| D2H | 02H | RAT_STALLS.REGISTERS | This event counts the number of cycles instruction execution latency became longer than the defined latency because the instruction used a register that was partially written by previous instruction. | |
| D2H | 04H | RAT_STALLS.ROB_READ_PORT | Counts the number of cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the out-of-order pipeline. Note that, at this stage in the pipeline, additional stalls may occur at the same cycle and prevent the stalled micro-ops from entering the pipe. In such a case, micro-ops retry entering the execution pipe in the next cycle and the ROB-read port stall is counted again. | |
| D2H | 08H | RAT_STALLS.SCOREBOARD | Counts the cycles where we stall due to microarchitecturally required serialization. Microcode scoreboarding stalls. | |
| D2H | 0FH | RAT_STALLS.ANY | Counts all Register Allocation Table stall cycles due to: Cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the execution pipe. Cycles when partial register stalls occurred Cycles when flag stalls occurred Cycles floating-point unit (FPU) status word stalls occurred. To count each of these conditions separately use the events: RAT_STALLS.ROB_READ_PORT, RAT_STALLS.PARTIAL, RAT_STALLS.FLAGS, and RAT_STALLS.FPSW. | |
| D4H | 01H | SEG_RENAME_STALLS | Counts the number of stall cycles due to the lack of renaming resources for the ES, DS, FS, and GS segment registers. If a segment is renamed but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires. | |
| D5H | 01H | ES_REG_RENAMES | Counts the number of times the ES segment register is renamed. | |
| DBH | 01H | UOP_UNFUSION | Counts unfusion events due to floating point exception to a fused uop. | |
| E0H | 01H | BR_INST_DECODED | Counts the number of branch instructions decoded. | |
| E5H | 01H | BPU_MISSED_CALL_RET | Counts number of times the Branch Prediciton Unit missed predicting a call or return branch. | |
| E6H | 01H | BACLEAR.CLEAR | Counts the number of times the front end is resteered, mainly when the Branch Prediction Unit cannot provide a correct prediction and this is corrected by the Branch Address Calculator at the front end. This can occur if the code has many branches such that they cannot be consumed by the BPU. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. The effect on total execution time depends on the surrounding code. | |

### Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| E6H | 02H | BACLEAR.BAD_TARGET | Counts number of Branch Address Calculator clears (BACLEAR) asserted due to conditional branch instructions in which there was a target hit but the direction was wrong. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. | |
| E8H | 01H | BPU_CLEARS.EARLY | Counts early (normal) Branch Prediction Unit clears: BPU predicted a taken branch after incorrectly assuming that it was not taken. | The BPU clear leads to 2 cycle bubble in the Front End. |
| E8H | 02H | BPU_CLEARS.LATE | Counts late Branch Prediction Unit clears due to Most Recently Used conflicts. The PBU clear leads to a 3 cycle bubble in the Front End. | |
| ECH | 01H | THREAD_ACTIVE | Counts cycles threads are active. | |
| F0H | 01H | L2_TRANSACTIONS.LOAD | Counts L2 load operations due to HW prefetch or demand loads. | |
| F0H | 02H | L2_TRANSACTIONS.RFO | Counts L2 RFO operations due to HW prefetch or demand RFOs. | |
| F0H | 04H | L2_TRANSACTIONS.IFETCH | Counts L2 instruction fetch operations due to HW prefetch or demand ifetch. | |
| F0H | 08H | L2_TRANSACTIONS.PREFETCH | Counts L2 prefetch operations. | |
| F0H | 10H | L2_TRANSACTIONS.L1D_WB | Counts L1D writeback operations to the L2. | |
| F0H | 20H | L2_TRANSACTIONS.FILL | Counts L2 cache line fill operations due to load, RFO, L1D writeback or prefetch. | |
| F0H | 40H | L2_TRANSACTIONS.WB | Counts L2 writeback operations to the L3. | |
| F0H | 80H | L2_TRANSACTIONS.ANY | Counts all L2 cache operations. | |
| F1H | 02H | L2_LINES_IN.S_STATE | Counts the number of cache lines allocated in the L2 cache in the S (shared) state. | |
| F1H | 04H | L2_LINES_IN.E_STATE | Counts the number of cache lines allocated in the L2 cache in the E (exclusive) state. | |
| F1H | 07H | L2_LINES_IN.ANY | Counts the number of cache lines allocated in the L2 cache. | |
| F2H | 01H | L2_LINES_OUT.DEMAND_CLEAN | Counts L2 clean cache lines evicted by a demand request. | |
| F2H | 02H | L2_LINES_OUT.DEMAND_DIRTY | Counts L2 dirty (modified) cache lines evicted by a demand request. | |
| F2H | 04H | L2_LINES_OUT.PREFETCH_CLEAN | Counts L2 clean cache line evicted by a prefetch request. | |
| F2H | 08H | L2_LINES_OUT.PREFETCH_DIRTY | Counts L2 modified cache line evicted by a prefetch request. | |
| F2H | 0FH | L2_LINES_OUT.ANY | Counts all L2 cache lines evicted for any reason. | |
| F4H | 04H | SQ_MISC.LRU_HINTS | Counts number of Super Queue LRU hints sent to L3. | |
| F4H | 10H | SQ_MISC.SPLIT_LOCK | Counts the number of SQ lock splits across a cache line. | |

Table 19-15. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| F6H | 01H | SQ_FULL_STALL_CYCLES | Counts cycles the Super Queue is full. Neither of the threads on this core will be able to access the uncore. | |
| F7H | 01H | FP_ASSIST.ALL | Counts the number of floating point operations executed that required micro-code assist intervention. Assists are required in the following cases: SSE instructions, (Denormal input when the DAZ flag is off or Underflow result when the FTZ flag is off): x87 instructions, (NaN or denormal are loaded to a register or used as input from memory, Division by 0 or Underflow output). | |
| F7H | 02H | FP_ASSIST.OUTPUT | Counts number of floating point micro-code assist when the output value (destination register) is invalid. | |
| F7H | 04H | FP_ASSIST.INPUT | Counts number of floating point micro-code assist when the input value (one of the source operands to an FP instruction) is invalid. | |
| FDH | 01H | SIMD_INT_64.PACKED_MPY | Counts number of SID integer 64 bit packed multiply operations. | |
| FDH | 02H | SIMD_INT_64.PACKED_SHIFT | Counts number of SID integer 64 bit packed shift operations. | |
| FDH | 04H | SIMD_INT_64.PACK | Counts number of SID integer 64 bit pack operations. | |
| FDH | 08H | SIMD_INT_64.UNPACK | Counts number of SID integer 64 bit unpack operations. | |
| FDH | 10H | SIMD_INT_64.PACKED_LOGICAL | Counts number of SID integer 64 bit logical operations. | |
| FDH | 20H | SIMD_INT_64.PACKED_ARITH | Counts number of SID integer 64 bit arithmetic operations. | |
| FDH | 40H | SIMD_INT_64.SHUFFLE_MOVE | Counts number of SID integer 64 bit shift or move operations. | |

Non-architectural Performance monitoring events of the uncore sub-system for Processors with CPUID signature of DisplayFamily_DisplayModel 06_25H, 06_2CH, and 06_1FH support performance events listed in Table 19-16.

**Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 00H | 01H | UNC_GQ_CYCLES_FULL.READ_TRACKER | Uncore cycles Global Queue read tracker is full. | |
| 00H | 02H | UNC_GQ_CYCLES_FULL.WRITE_TRACKER | Uncore cycles Global Queue write tracker is full. | |
| 00H | 04H | UNC_GQ_CYCLES_FULL.PEER_PROBE_TRACKER | Uncore cycles Global Queue peer probe tracker is full. The peer probe tracker queue tracks snoops from the IOH and remote sockets. | |
| 01H | 01H | UNC_GQ_CYCLES_NOT_EMPTY.READ_TRACKER | Uncore cycles were Global Queue read tracker has at least one valid entry. | |
| 01H | 02H | UNC_GQ_CYCLES_NOT_EMPTY.WRITE_TRACKER | Uncore cycles were Global Queue write tracker has at least one valid entry. | |
| 01H | 04H | UNC_GQ_CYCLES_NOT_EMPTY.PEER_PROBE_TRACKER | Uncore cycles were Global Queue peer probe tracker has at least one valid entry. The peer probe tracker queue tracks IOH and remote socket snoops. | |
| 02H | 01H | UNC_GQ_OCCUPANCY.READ_TRACKER | Increments the number of queue entries (code read, data read, and RFOs) in the tread tracker. The GQ read tracker allocate to deallocate occupancy count is divided by the count to obtain the average read tracker latency. | |
| 03H | 01H | UNC_GQ_ALLOC.READ_TRACKER | Counts the number of tread tracker allocate to deallocate entries. The GQ read tracker allocate to deallocate occupancy count is divided by the count to obtain the average read tracker latency. | |
| 03H | 02H | UNC_GQ_ALLOC.RT_L3_MISS | Counts the number GQ read tracker entries for which a full cache line read has missed the L3. The GQ read tracker L3 miss to fill occupancy count is divided by this count to obtain the average cache line read L3 miss latency. The latency represents the time after which the L3 has determined that the cache line has missed. The time between a GQ read tracker allocation and the L3 determining that the cache line has missed is the average L3 hit latency. The total L3 cache line read miss latency is the hit latency + L3 miss latency. | |
| 03H | 04H | UNC_GQ_ALLOC.RT_TO_L3_RESP | Counts the number of GQ read tracker entries that are allocated in the read tracker queue that hit or miss the L3. The GQ read tracker L3 hit occupancy count is divided by this count to obtain the average L3 hit latency. | |
| 03H | 08H | UNC_GQ_ALLOC.RT_TO_RTID_ACQUIRED | Counts the number of GQ read tracker entries that are allocated in the read tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ read tracker L3 miss to RTID acquired occupancy count is divided by this count to obtain the average latency for a read L3 miss to acquire an RTID. | |

Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 03H | 10H | UNC_GQ_ALLOC.WT_TO_RTID_ACQUIRED | Counts the number of GQ write tracker entries that are allocated in the write tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ write tracker L3 miss to RTID occupancy count is divided by this count to obtain the average latency for a write L3 miss to acquire an RTID. | |
| 03H | 20H | UNC_GQ_ALLOC.WRITE_TRACKER | Counts the number of GQ write tracker entries that are allocated in the write tracker queue that miss the L3. The GQ write tracker occupancy count is divided by the this count to obtain the average L3 write miss latency. | |
| 03H | 40H | UNC_GQ_ALLOC.PEER_PROBE_TRACKER | Counts the number of GQ peer probe tracker (snoop) entries that are allocated in the peer probe tracker queue that miss the L3. The GQ peer probe occupancy count is divided by this count to obtain the average L3 peer probe miss latency. | |
| 04H | 01H | UNC_GQ_DATA.FROM_QPI | Cycles Global Queue Quickpath Interface input data port is busy importing data from the Quickpath Interface. Each cycle the input port can transfer 8 or 16 bytes of data. | |
| 04H | 02H | UNC_GQ_DATA.FROM_QMC | Cycles Global Queue Quickpath Memory Interface input data port is busy importing data from the Quickpath Memory Interface. Each cycle the input port can transfer 8 or 16 bytes of data. | |
| 04H | 04H | UNC_GQ_DATA.FROM_L3 | Cycles GQ L3 input data port is busy importing data from the Last Level Cache. Each cycle the input port can transfer 32 bytes of data. | |
| 04H | 08H | UNC_GQ_DATA.FROM_CORES_02 | Cycles GQ Core 0 and 2 input data port is busy importing data from processor cores 0 and 2. Each cycle the input port can transfer 32 bytes of data. | |
| 04H | 10H | UNC_GQ_DATA.FROM_CORES_13 | Cycles GQ Core 1 and 3 input data port is busy importing data from processor cores 1 and 3. Each cycle the input port can transfer 32 bytes of data. | |
| 05H | 01H | UNC_GQ_DATA.TO_QPI_QMC | Cycles GQ QPI and QMC output data port is busy sending data to the Quickpath Interface or Quickpath Memory Interface. Each cycle the output port can transfer 32 bytes of data. | |
| 05H | 02H | UNC_GQ_DATA.TO_L3 | Cycles GQ L3 output data port is busy sending data to the Last Level Cache. Each cycle the output port can transfer 32 bytes of data. | |
| 05H | 04H | UNC_GQ_DATA.TO_CORES | Cycles GQ Core output data port is busy sending data to the Cores. Each cycle the output port can transfer 32 bytes of data. | |
| 06H | 01H | UNC_SNP_RESP_TO_LOCAL_HOME.I_STATE | Number of snoop responses to the local home that L3 does not have the referenced cache line. | |
| 06H | 02H | UNC_SNP_RESP_TO_LOCAL_HOME.S_STATE | Number of snoop responses to the local home that L3 has the referenced line cached in the S state. | |

**Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 06H | 04H | UNC_SNP_RESP_TO_LOCAL_HOME.FWD_S_STATE | Number of responses to code or data read snoops to the local home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the local home in the S state. | |
| 06H | 08H | UNC_SNP_RESP_TO_LOCAL_HOME.FWD_I_STATE | Number of responses to read invalidate snoops to the local home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the local home in the M state. | |
| 06H | 10H | UNC_SNP_RESP_TO_LOCAL_HOME.CONFLICT | Number of conflict snoop responses sent to the local home. | |
| 06H | 20H | UNC_SNP_RESP_TO_LOCAL_HOME.WB | Number of responses to code or data read snoops to the local home that the L3 has the referenced line cached in the M state. | |
| 07H | 01H | UNC_SNP_RESP_TO_REMOTE_HOME.I_STATE | Number of snoop responses to a remote home that L3 does not have the referenced cache line. | |
| 07H | 02H | UNC_SNP_RESP_TO_REMOTE_HOME.S_STATE | Number of snoop responses to a remote home that L3 has the referenced line cached in the S state. | |
| 07H | 04H | UNC_SNP_RESP_TO_REMOTE_HOME.FWD_S_STATE | Number of responses to code or data read snoops to a remote home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the remote home in the S state. | |
| 07H | 08H | UNC_SNP_RESP_TO_REMOTE_HOME.FWD_I_STATE | Number of responses to read invalidate snoops to a remote home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the remote home in the M state. | |
| 07H | 10H | UNC_SNP_RESP_TO_REMOTE_HOME.CONFLICT | Number of conflict snoop responses sent to the local home. | |
| 07H | 20H | UNC_SNP_RESP_TO_REMOTE_HOME.WB | Number of responses to code or data read snoops to a remote home that the L3 has the referenced line cached in the M state. | |
| 07H | 24H | UNC_SNP_RESP_TO_REMOTE_HOME.HITM | Number of HITM snoop responses to a remote home | |
| 08H | 01H | UNC_L3_HITS.READ | Number of code read, data read and RFO requests that hit in the L3 | |
| 08H | 02H | UNC_L3_HITS.WRITE | Number of writeback requests that hit in the L3. Writebacks from the cores will always result in L3 hits due to the inclusive property of the L3. | |
| 08H | 04H | UNC_L3_HITS.PROBE | Number of snoops from IOH or remote sockets that hit in the L3. | |
| 08H | 03H | UNC_L3_HITS.ANY | Number of reads and writes that hit the L3. | |
| 09H | 01H | UNC_L3_MISS.READ | Number of code read, data read and RFO requests that miss the L3. | |

## Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 09H | 02H | UNC_L3_MISS.WRITE | Number of writeback requests that miss the L3. Should always be zero as writebacks from the cores will always result in L3 hits due to the inclusive property of the L3. | |
| 09H | 04H | UNC_L3_MISS.PROBE | Number of snoops from IOH or remote sockets that miss the L3. | |
| 09H | 03H | UNC_L3_MISS.ANY | Number of reads and writes that miss the L3. | |
| 0AH | 01H | UNC_L3_LINES_IN.M_STATE | Counts the number of L3 lines allocated in M state. The only time a cache line is allocated in the M state is when the line was forwarded in M state is forwarded due to a Snoop Read Invalidate Own request. | |
| 0AH | 02H | UNC_L3_LINES_IN.E_STATE | Counts the number of L3 lines allocated in E state. | |
| 0AH | 04H | UNC_L3_LINES_IN.S_STATE | Counts the number of L3 lines allocated in S state. | |
| 0AH | 08H | UNC_L3_LINES_IN.F_STATE | Counts the number of L3 lines allocated in F state. | |
| 0AH | 0FH | UNC_L3_LINES_IN.ANY | Counts the number of L3 lines allocated in any state. | |
| 0BH | 01H | UNC_L3_LINES_OUT.M_STATE | Counts the number of L3 lines victimized that were in the M state. When the victim cache line is in M state, the line is written to its home cache agent which can be either local or remote. | |
| 0BH | 02H | UNC_L3_LINES_OUT.E_STATE | Counts the number of L3 lines victimized that were in the E state. | |
| 0BH | 04H | UNC_L3_LINES_OUT.S_STATE | Counts the number of L3 lines victimized that were in the S state. | |
| 0BH | 08H | UNC_L3_LINES_OUT.I_STATE | Counts the number of L3 lines victimized that were in the I state. | |
| 0BH | 10H | UNC_L3_LINES_OUT.F_STATE | Counts the number of L3 lines victimized that were in the F state. | |
| 0BH | 1FH | UNC_L3_LINES_OUT.ANY | Counts the number of L3 lines victimized in any state. | |
| 0CH | 01H | UNC_GQ_SNOOP.GOTO_S | Counts the number of remote snoops that have requested a cache line be set to the S state. | |
| 0CH | 02H | UNC_GQ_SNOOP.GOTO_I | Counts the number of remote snoops that have requested a cache line be set to the I state. | |
| 0CH | 04H | UNC_GQ_SNOOP.GOTO_S_HIT_E | Counts the number of remote snoops that have requested a cache line be set to the S state from E state. | Requires writing MSR 301H with mask = 2H |
| 0CH | 04H | UNC_GQ_SNOOP.GOTO_S_HIT_F | Counts the number of remote snoops that have requested a cache line be set to the S state from F (forward) state. | Requires writing MSR 301H with mask = 8H |
| 0CH | 04H | UNC_GQ_SNOOP.GOTO_S_HIT_M | Counts the number of remote snoops that have requested a cache line be set to the S state from M state. | Requires writing MSR 301H with mask = 1H |
| 0CH | 04H | UNC_GQ_SNOOP.GOTO_S_HIT_S | Counts the number of remote snoops that have requested a cache line be set to the S state from S state. | Requires writing MSR 301H with mask = 4H |
| 0CH | 08H | UNC_GQ_SNOOP.GOTO_I_HIT_E | Counts the number of remote snoops that have requested a cache line be set to the I state from E state. | Requires writing MSR 301H with mask = 2H |

**Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 0CH | 08H | UNC_GQ_SNOOP.GOTO_I_HIT_F | Counts the number of remote snoops that have requested a cache line be set to the I state from F (forward) state. | Requires writing MSR 301H with mask = 8H |
| 0CH | 08H | UNC_GQ_SNOOP.GOTO_I_HIT_M | Counts the number of remote snoops that have requested a cache line be set to the I state from M state. | Requires writing MSR 301H with mask = 1H |
| 0CH | 08H | UNC_GQ_SNOOP.GOTO_I_HIT_S | Counts the number of remote snoops that have requested a cache line be set to the I state from S state. | Requires writing MSR 301H with mask = 4H |
| 20H | 01H | UNC_QHL_REQUESTS.IOH_READS | Counts number of Quickpath Home Logic read requests from the IOH. | |
| 20H | 02H | UNC_QHL_REQUESTS.IOH_WRITES | Counts number of Quickpath Home Logic write requests from the IOH. | |
| 20H | 04H | UNC_QHL_REQUESTS.REMOTE_READS | Counts number of Quickpath Home Logic read requests from a remote socket. | |
| 20H | 08H | UNC_QHL_REQUESTS.REMOTE_WRITES | Counts number of Quickpath Home Logic write requests from a remote socket. | |
| 20H | 10H | UNC_QHL_REQUESTS.LOCAL_READS | Counts number of Quickpath Home Logic read requests from the local socket. | |
| 20H | 20H | UNC_QHL_REQUESTS.LOCAL_WRITES | Counts number of Quickpath Home Logic write requests from the local socket. | |
| 21H | 01H | UNC_QHL_CYCLES_FULL.IOH | Counts uclk cycles all entries in the Quickpath Home Logic IOH are full. | |
| 21H | 02H | UNC_QHL_CYCLES_FULL.REMOTE | Counts uclk cycles all entries in the Quickpath Home Logic remote tracker are full. | |
| 21H | 04H | UNC_QHL_CYCLES_FULL.LOCAL | Counts uclk cycles all entries in the Quickpath Home Logic local tracker are full. | |
| 22H | 01H | UNC_QHL_CYCLES_NOT_EMPTY.IOH | Counts uclk cycles all entries in the Quickpath Home Logic IOH is busy. | |
| 22H | 02H | UNC_QHL_CYCLES_NOT_EMPTY.REMOTE | Counts uclk cycles all entries in the Quickpath Home Logic remote tracker is busy. | |
| 22H | 04H | UNC_QHL_CYCLES_NOT_EMPTY.LOCAL | Counts uclk cycles all entries in the Quickpath Home Logic local tracker is busy. | |
| 23H | 01H | UNC_QHL_OCCUPANCY.IOH | QHL IOH tracker allocate to deallocate read occupancy. | |
| 23H | 02H | UNC_QHL_OCCUPANCY.REMOTE | QHL remote tracker allocate to deallocate read occupancy. | |
| 23H | 04H | UNC_QHL_OCCUPANCY.LOCAL | QHL local tracker allocate to deallocate read occupancy. | |
| 24H | 02H | UNC_QHL_ADDRESS_CONFLICTS.2WAY | Counts number of QHL Active Address Table (AAT) entries that saw a max of 2 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates. | |

Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 24H | 04H | UNC_QHL_ADDRESS_CONFLICTS.3WAY | Counts number of QHL Active Address Table (AAT) entries that saw a max of 3 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates. | |
| 25H | 01H | UNC_QHL_CONFLICT_CYCLES.IOH | Counts cycles the Quickpath Home Logic IOH Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict. | |
| 25H | 02H | UNC_QHL_CONFLICT_CYCLES.REMOTE | Counts cycles the Quickpath Home Logic Remote Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict. | |
| 25H | 04H | UNC_QHL_CONFLICT_CYCLES.LOCAL | Counts cycles the Quickpath Home Logic Local Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict. | |
| 26H | 01H | UNC_QHL_TO_QMC_BYPASS | Counts number or requests to the Quickpath Memory Controller that bypass the Quickpath Home Logic. All local accesses can be bypassed. For remote requests, only read requests can be bypassed. | |
| 28H | 01H | UNC_QMC_ISOC_FULL.READ.CH0 | Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous read requests. | |
| 28H | 02H | UNC_QMC_ISOC_FULL.READ.CH1 | Counts cycles all the entries in the DRAM channel 1high priority queue are occupied with isochronous read requests. | |
| 28H | 04H | UNC_QMC_ISOC_FULL.READ.CH2 | Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous read requests. | |
| 28H | 08H | UNC_QMC_ISOC_FULL.WRITE.CH0 | Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous write requests. | |
| 28H | 10H | UNC_QMC_ISOC_FULL.WRITE.CH1 | Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous write requests. | |
| 28H | 20H | UNC_QMC_ISOC_FULL.WRITE.CH2 | Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous write requests. | |
| 29H | 01H | UNC_QMC_BUSY.READ.CH0 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 0. | |
| 29H | 02H | UNC_QMC_BUSY.READ.CH1 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 1. | |
| 29H | 04H | UNC_QMC_BUSY.READ.CH2 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 2. | |
| 29H | 08H | UNC_QMC_BUSY.WRITE.CH0 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 0. | |

**Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 29H | 10H | UNC_QMC_BUSY.WRITE.CH1 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 1. | |
| 29H | 20H | UNC_QMC_BUSY.WRITE.CH2 | Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 2. | |
| 2AH | 01H | UNC_QMC_OCCUPANCY.CH0 | IMC channel 0 normal read request occupancy. | |
| 2AH | 02H | UNC_QMC_OCCUPANCY.CH1 | IMC channel 1 normal read request occupancy. | |
| 2AH | 04H | UNC_QMC_OCCUPANCY.CH2 | IMC channel 2 normal read request occupancy. | |
| 2AH | 07H | UNC_QMC_OCCUPANCY.ANY | Normal read request occupancy for any channel. | |
| 2BH | 01H | UNC_QMC_ISSOC_OCCUPANCY.CH0 | IMC channel 0 issoc read request occupancy. | |
| 2BH | 02H | UNC_QMC_ISSOC_OCCUPANCY.CH1 | IMC channel 1 issoc read request occupancy. | |
| 2BH | 04H | UNC_QMC_ISSOC_OCCUPANCY.CH2 | IMC channel 2 issoc read request occupancy. | |
| 2BH | 07H | UNC_QMC_ISSOC_READS.ANY | IMC issoc read request occupancy. | |
| 2CH | 01H | UNC_QMC_NORMAL_READS.CH0 | Counts the number of Quickpath Memory Controller channel 0 medium and low priority read requests. The QMC channel 0 normal read occupancy divided by this count provides the average QMC channel 0 read latency. | |
| 2CH | 02H | UNC_QMC_NORMAL_READS.CH1 | Counts the number of Quickpath Memory Controller channel 1 medium and low priority read requests. The QMC channel 1 normal read occupancy divided by this count provides the average QMC channel 1 read latency. | |
| 2CH | 04H | UNC_QMC_NORMAL_READS.CH2 | Counts the number of Quickpath Memory Controller channel 2 medium and low priority read requests. The QMC channel 2 normal read occupancy divided by this count provides the average QMC channel 2 read latency. | |
| 2CH | 07H | UNC_QMC_NORMAL_READS.ANY | Counts the number of Quickpath Memory Controller medium and low priority read requests. The QMC normal read occupancy divided by this count provides the average QMC read latency. | |
| 2DH | 01H | UNC_QMC_HIGH_PRIORITY_READS.CH0 | Counts the number of Quickpath Memory Controller channel 0 high priority isochronous read requests. | |
| 2DH | 02H | UNC_QMC_HIGH_PRIORITY_READS.CH1 | Counts the number of Quickpath Memory Controller channel 1 high priority isochronous read requests. | |
| 2DH | 04H | UNC_QMC_HIGH_PRIORITY_READS.CH2 | Counts the number of Quickpath Memory Controller channel 2 high priority isochronous read requests. | |
| 2DH | 07H | UNC_QMC_HIGH_PRIORITY_READS.ANY | Counts the number of Quickpath Memory Controller high priority isochronous read requests. | |
| 2EH | 01H | UNC_QMC_CRITICAL_PRIORITY_READS.CH0 | Counts the number of Quickpath Memory Controller channel 0 critical priority isochronous read requests. | |

Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 2EH | 02H | UNC_QMC_CRITICAL_PRIORITY_READS.CH1 | Counts the number of Quickpath Memory Controller channel 1 critical priority isochronous read requests. | |
| 2EH | 04H | UNC_QMC_CRITICAL_PRIORITY_READS.CH2 | Counts the number of Quickpath Memory Controller channel 2 critical priority isochronous read requests. | |
| 2EH | 07H | UNC_QMC_CRITICAL_PRIORITY_READS.ANY | Counts the number of Quickpath Memory Controller critical priority isochronous read requests. | |
| 2FH | 01H | UNC_QMC_WRITES.FULL.CH0 | Counts number of full cache line writes to DRAM channel 0. | |
| 2FH | 02H | UNC_QMC_WRITES.FULL.CH1 | Counts number of full cache line writes to DRAM channel 1. | |
| 2FH | 04H | UNC_QMC_WRITES.FULL.CH2 | Counts number of full cache line writes to DRAM channel 2. | |
| 2FH | 07H | UNC_QMC_WRITES.FULL.ANY | Counts number of full cache line writes to DRAM. | |
| 2FH | 08H | UNC_QMC_WRITES.PARTIAL.CH0 | Counts number of partial cache line writes to DRAM channel 0. | |
| 2FH | 10H | UNC_QMC_WRITES.PARTIAL.CH1 | Counts number of partial cache line writes to DRAM channel 1. | |
| 2FH | 20H | UNC_QMC_WRITES.PARTIAL.CH2 | Counts number of partial cache line writes to DRAM channel 2. | |
| 2FH | 38H | UNC_QMC_WRITES.PARTIAL.ANY | Counts number of partial cache line writes to DRAM. | |
| 30H | 01H | UNC_QMC_CANCEL.CH0 | Counts number of DRAM channel 0 cancel requests. | |
| 30H | 02H | UNC_QMC_CANCEL.CH1 | Counts number of DRAM channel 1 cancel requests. | |
| 30H | 04H | UNC_QMC_CANCEL.CH2 | Counts number of DRAM channel 2 cancel requests. | |
| 30H | 07H | UNC_QMC_CANCEL.ANY | Counts number of DRAM cancel requests. | |
| 31H | 01H | UNC_QMC_PRIORITY_UPDATES.CH0 | Counts number of DRAM channel 0 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. | |
| 31H | 02H | UNC_QMC_PRIORITY_UPDATES.CH1 | Counts number of DRAM channel 1 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. | |
| 31H | 04H | UNC_QMC_PRIORITY_UPDATES.CH2 | Counts number of DRAM channel 2 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. | |

**Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 31H | 07H | UNC_QMC_PRIORITY_UPDATES.ANY | Counts number of DRAM priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request. | |
| 32H | 01H | UNC_IMC_RETRY.CH0 | Counts number of IMC DRAM channel 0 retries. DRAM retry only occurs when configured in RAS mode. | |
| 32H | 02H | UNC_IMC_RETRY.CH1 | Counts number of IMC DRAM channel 1 retries. DRAM retry only occurs when configured in RAS mode. | |
| 32H | 04H | UNC_IMC_RETRY.CH2 | Counts number of IMC DRAM channel 2 retries. DRAM retry only occurs when configured in RAS mode. | |
| 32H | 07H | UNC_IMC_RETRY.ANY | Counts number of IMC DRAM retries from any channel. DRAM retry only occurs when configured in RAS mode. | |
| 33H | 01H | UNC_QHL_FRC_ACK_CNFLTS.IOH | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the IOH. | |
| 33H | 02H | UNC_QHL_FRC_ACK_CNFLTS.REMOTE | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the remote home. | |
| 33H | 04H | UNC_QHL_FRC_ACK_CNFLTS.LOCAL | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the local home. | |
| 33H | 07H | UNC_QHL_FRC_ACK_CNFLTS.ANY | Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic. | |
| 34H | 01H | UNC_QHL_SLEEPS.IOH_ORDER | Counts number of occurrences a request was put to sleep due to IOH ordering (write after read) conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC. | |
| 34H | 02H | UNC_QHL_SLEEPS.REMOTE_ORDER | Counts number of occurrences a request was put to sleep due to remote socket ordering (write after read) conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC. | |
| 34H | 04H | UNC_QHL_SLEEPS.LOCAL_ORDER | Counts number of occurrences a request was put to sleep due to local socket ordering (write after read) conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC. | |
| 34H | 08H | UNC_QHL_SLEEPS.IOH_CONFLICT | Counts number of occurrences a request was put to sleep due to IOH address conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC. | |
| 34H | 10H | UNC_QHL_SLEEPS.REMOTE_CONFLICT | Counts number of occurrences a request was put to sleep due to remote socket address conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC. | |
| 34H | 20H | UNC_QHL_SLEEPS.LOCAL_CONFLICT | Counts number of occurrences a request was put to sleep due to local socket address conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC. | |

Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 35H | 01H | UNC_ADDR_OPCODE_MATCH.IOH | Counts number of requests from the IOH, address/opcode of request is qualified by mask value written to MSR 396H. The following mask values are supported:<br>0: NONE<br>40000000_00000000H:RSPFWDI<br>40001A00_00000000H:RSPFWDS<br>40001D00_00000000H:RSPIWB | Match opcode/address by writing MSR 396H with mask supported mask value |
| 35H | 02H | UNC_ADDR_OPCODE_MATCH.REMOTE | Counts number of requests from the remote socket, address/opcode of request is qualified by mask value written to MSR 396H. The following mask values are supported:<br>0: NONE<br>40000000_00000000H:RSPFWDI<br>40001A00_00000000H:RSPFWDS<br>40001D00_00000000H:RSPIWB | Match opcode/address by writing MSR 396H with mask supported mask value |
| 35H | 04H | UNC_ADDR_OPCODE_MATCH.LOCAL | Counts number of requests from the local socket, address/opcode of request is qualified by mask value written to MSR 396H. The following mask values are supported:<br>0: NONE<br>40000000_00000000H:RSPFWDI<br>40001A00_00000000H:RSPFWDS<br>40001D00_00000000H:RSPIWB | Match opcode/address by writing MSR 396H with mask supported mask value |
| 40H | 01H | UNC_QPI_TX_STALLED_SINGLE_FLIT.HOME.LINK_0 | Counts cycles the Quickpath outbound link 0 HOME virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 02H | UNC_QPI_TX_STALLED_SINGLE_FLIT.SNOOP.LINK_0 | Counts cycles the Quickpath outbound link 0 SNOOP virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 04H | UNC_QPI_TX_STALLED_SINGLE_FLIT.NDR.LINK_0 | Counts cycles the Quickpath outbound link 0 non-data response virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 08H | UNC_QPI_TX_STALLED_SINGLE_FLIT.HOME.LINK_1 | Counts cycles the Quickpath outbound link 1 HOME virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |

**Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 40H | 10H | UNC_QPI_TX_STALLED_SINGLE_FLIT.SNOOP.LINK_1 | Counts cycles the Quickpath outbound link 1 SNOOP virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 20H | UNC_QPI_TX_STALLED_SINGLE_FLIT.NDR.LINK_1 | Counts cycles the Quickpath outbound link 1 non-data response virtual channel is stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 07H | UNC_QPI_TX_STALLED_SINGLE_FLIT.LINK_0 | Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 40H | 38H | UNC_QPI_TX_STALLED_SINGLE_FLIT.LINK_1 | Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of a VNA and VN0 credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 01H | UNC_QPI_TX_STALLED_MULTI_FLIT.DRS.LINK_0 | Counts cycles the Quickpath outbound link 0 Data ResponSe virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 02H | UNC_QPI_TX_STALLED_MULTI_FLIT.NCB.LINK_0 | Counts cycles the Quickpath outbound link 0 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 04H | UNC_QPI_TX_STALLED_MULTI_FLIT.NCS.LINK_0 | Counts cycles the Quickpath outbound link 0 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 08H | UNC_QPI_TX_STALLED_MULTI_FLIT.DRS.LINK_1 | Counts cycles the Quickpath outbound link 1 Data ResponSe virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 10H | UNC_QPI_TX_STALLED_MULTI_FLIT.NCB.LINK_1 | Counts cycles the Quickpath outbound link 1 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |

Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 41H | 20H | UNC_QPI_TX_STALLED_MULTI_FLIT.NCS.LINK_1 | Counts cycles the Quickpath outbound link 1 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 07H | UNC_QPI_TX_STALLED_MULTI_FLIT.LINK_0 | Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 41H | 38H | UNC_QPI_TX_STALLED_MULTI_FLIT.LINK_1 | Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of VNA and VN0 credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated. | |
| 42H | 01H | UNC_QPI_TX_HEADER.FULL.LINK_0 | Number of cycles that the header buffer in the Quickpath Interface outbound link 0 is full. | |
| 42H | 02H | UNC_QPI_TX_HEADER.BUSY.LINK_0 | Number of cycles that the header buffer in the Quickpath Interface outbound link 0 is busy. | |
| 42H | 04H | UNC_QPI_TX_HEADER.FULL.LINK_1 | Number of cycles that the header buffer in the Quickpath Interface outbound link 1 is full. | |
| 42H | 08H | UNC_QPI_TX_HEADER.BUSY.LINK_1 | Number of cycles that the header buffer in the Quickpath Interface outbound link 1 is busy. | |
| 43H | 01H | UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_0 | Number of cycles that snoop packets incoming to the Quickpath Interface link 0 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries. | |
| 43H | 02H | UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_1 | Number of cycles that snoop packets incoming to the Quickpath Interface link 1 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries. | |
| 60H | 01H | UNC_DRAM_OPEN.CH0 | Counts number of DRAM Channel 0 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened. | |
| 60H | 02H | UNC_DRAM_OPEN.CH1 | Counts number of DRAM Channel 1 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened. | |
| 60H | 04H | UNC_DRAM_OPEN.CH2 | Counts number of DRAM Channel 2 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened. | |
| 61H | 01H | UNC_DRAM_PAGE_CLOSE.CH0 | DRAM channel 0 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge. | |
| 61H | 02H | UNC_DRAM_PAGE_CLOSE.CH1 | DRAM channel 1 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge. | |

**Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 61H | 04H | UNC_DRAM_PAGE_CLOSE.CH2 | DRAM channel 2 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge. | |
| 62H | 01H | UNC_DRAM_PAGE_MISS.CH0 | Counts the number of precharges (PRE) that were issued to DRAM channel 0 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. | |
| 62H | 02H | UNC_DRAM_PAGE_MISS.CH1 | Counts the number of precharges (PRE) that were issued to DRAM channel 1 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. | |
| 62H | 04H | UNC_DRAM_PAGE_MISS.CH2 | Counts the number of precharges (PRE) that were issued to DRAM channel 2 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge. | |
| 63H | 01H | UNC_DRAM_READ_CAS.CH0 | Counts the number of times a read CAS command was issued on DRAM channel 0. | |
| 63H | 02H | UNC_DRAM_READ_CAS.AUTO PRE_CH0 | Counts the number of times a read CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode. | |
| 63H | 04H | UNC_DRAM_READ_CAS.CH1 | Counts the number of times a read CAS command was issued on DRAM channel 1. | |
| 63H | 08H | UNC_DRAM_READ_CAS.AUTO PRE_CH1 | Counts the number of times a read CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode. | |
| 63H | 10H | UNC_DRAM_READ_CAS.CH2 | Counts the number of times a read CAS command was issued on DRAM channel 2. | |
| 63H | 20H | UNC_DRAM_READ_CAS.AUTO PRE_CH2 | Counts the number of times a read CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode. | |
| 64H | 01H | UNC_DRAM_WRITE_CAS.CH0 | Counts the number of times a write CAS command was issued on DRAM channel 0. | |
| 64H | 02H | UNC_DRAM_WRITE_CAS.AUTO PRE_CH0 | Counts the number of times a write CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode. | |
| 64H | 04H | UNC_DRAM_WRITE_CAS.CH1 | Counts the number of times a write CAS command was issued on DRAM channel 1. | |
| 64H | 08H | UNC_DRAM_WRITE_CAS.AUTO PRE_CH1 | Counts the number of times a write CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode. | |

## Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 64H | 10H | UNC_DRAM_WRITE_CAS.CH2 | Counts the number of times a write CAS command was issued on DRAM channel 2. | |
| 64H | 20H | UNC_DRAM_WRITE_CAS.AUTO PRE_CH2 | Counts the number of times a write CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode. | |
| 65H | 01H | UNC_DRAM_REFRESH.CH0 | Counts number of DRAM channel 0 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically. | |
| 65H | 02H | UNC_DRAM_REFRESH.CH1 | Counts number of DRAM channel 1 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically. | |
| 65H | 04H | UNC_DRAM_REFRESH.CH2 | Counts number of DRAM channel 2 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically. | |
| 66H | 01H | UNC_DRAM_PRE_ALL.CH0 | Counts number of DRAM Channel 0 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. | |
| 66H | 02H | UNC_DRAM_PRE_ALL.CH1 | Counts number of DRAM Channel 1 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. | |
| 66H | 04H | UNC_DRAM_PRE_ALL.CH2 | Counts number of DRAM Channel 2 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode. | |
| 67H | 01H | UNC_DRAM_THERMAL_THROT TLED | Uncore cycles DRAM was throttled due to its temperature being above the thermal throttling threshold. | |
| 80H | 01H | UNC_THERMAL_THROTTLING_ TEMP.CORE_0 | Cycles that the PCU records that core 0 is above the thermal throttling threshold temperature. | |
| 80H | 02H | UNC_THERMAL_THROTTLING_ TEMP.CORE_1 | Cycles that the PCU records that core 1 is above the thermal throttling threshold temperature. | |
| 80H | 04H | UNC_THERMAL_THROTTLING_ TEMP.CORE_2 | Cycles that the PCU records that core 2 is above the thermal throttling threshold temperature. | |
| 80H | 08H | UNC_THERMAL_THROTTLING_ TEMP.CORE_3 | Cycles that the PCU records that core 3 is above the thermal throttling threshold temperature. | |
| 81H | 01H | UNC_THERMAL_THROTTLED_ TEMP.CORE_0 | Cycles that the PCU records that core 0 is in the power throttled state due to core's temperature being above the thermal throttling threshold. | |
| 81H | 02H | UNC_THERMAL_THROTTLED_ TEMP.CORE_1 | Cycles that the PCU records that core 1 is in the power throttled state due to core's temperature being above the thermal throttling threshold. | |

**Table 19-16. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| 81H | 04H | UNC_THERMAL_THROTTLED_TEMP.CORE_2 | Cycles that the PCU records that core 2 is in the power throttled state due to core's temperature being above the thermal throttling threshold. | |
| 81H | 08H | UNC_THERMAL_THROTTLED_TEMP.CORE_3 | Cycles that the PCU records that core 3 is in the power throttled state due to core's temperature being above the thermal throttling threshold. | |
| 82H | 01H | UNC_PROCHOT_ASSERTION | Number of system assertions of PROCHOT indicating the entire processor has exceeded the thermal limit. | |
| 83H | 01H | UNC_THERMAL_THROTTLING_PROCHOT.CORE_0 | Cycles that the PCU records that core 0 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit. | |
| 83H | 02H | UNC_THERMAL_THROTTLING_PROCHOT.CORE_1 | Cycles that the PCU records that core 1 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit. | |
| 83H | 04H | UNC_THERMAL_THROTTLING_PROCHOT.CORE_2 | Cycles that the PCU records that core 2 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit. | |
| 83H | 08H | UNC_THERMAL_THROTTLING_PROCHOT.CORE_3 | Cycles that the PCU records that core 3 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit. | |
| 84H | 01H | UNC_TURBO_MODE.CORE_0 | Uncore cycles that core 0 is operating in turbo mode. | |
| 84H | 02H | UNC_TURBO_MODE.CORE_1 | Uncore cycles that core 1 is operating in turbo mode. | |
| 84H | 04H | UNC_TURBO_MODE.CORE_2 | Uncore cycles that core 2 is operating in turbo mode. | |
| 84H | 08H | UNC_TURBO_MODE.CORE_3 | Uncore cycles that core 3 is operating in turbo mode. | |
| 85H | 02H | UNC_CYCLES_UNHALTED_L3_FLL_ENABLE | Uncore cycles that at least one core is unhalted and all L3 ways are enabled. | |
| 86H | 01H | UNC_CYCLES_UNHALTED_L3_FLL_DISABLE | Uncore cycles that at least one core is unhalted and all L3 ways are disabled. | |

## 19.8 PERFORMANCE MONITORING EVENTS FOR INTEL® XEON® PROCESSOR 5200, 5400 SERIES AND INTEL® CORE™2 EXTREME PROCESSORS QX 9000 SERIES

Processors based on the Enhanced Intel Core microarchitecture support the architectural and non-architectural performance-monitoring events listed in Table 19-1 and Table 19-19. In addition, they also support the following non-architectural performance-monitoring events listed in Table 19-17. Fixed counters support the architecture events defined in Table 19-18.

**Table 19-17. Non-Architectural Performance Events for Processors Based on Enhanced Intel Core Microarchitecture**

| Event Num. | Umask Value | Event Mask Mnemonic | Description | Comment |
|---|---|---|---|---|
| C0H | 08H | INST_RETIRED.VM_HOST | Instruction retired while in VMX root operations. | |
| D2H | 10H | RAT_STAALS.OTHER_SERIALIZATION_STALLS | This events counts the number of stalls due to other RAT resource serialization not counted by Umask value 0FH. | |

## 19.9 PERFORMANCE MONITORING EVENTS FOR INTEL® XEON® PROCESSOR 3000, 3200, 5100, 5300 SERIES AND INTEL® CORE™2 DUO PROCESSORS

Processors based on the Intel® Core™ microarchitecture support architectural and non-architectural performance-monitoring events.

Fixed-function performance counters are introduced first on processors based on Intel Core microarchitecture. Table 19-18 lists pre-defined performance events that can be counted using fixed-function performance counters.

**Table 19-18. Fixed-Function Performance Counter and Pre-defined Performance Events**

| Fixed-Function Performance Counter | Address | Event Mask Mnemonic | Description |
|---|---|---|---|
| MSR_PERF_FIXED_CTR0/IA32_PERF_FIXED_CTR0 | 309H | Inst_Retired.Any | This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continue counting during hardware interrupts, traps, and inside interrupt handlers. |
| MSR_PERF_FIXED_CTR1/IA32_PERF_FIXED_CTR1 | 30AH | CPU_CLK_UNHALTED.CORE | This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. This event is a component in many key event ratios.<br>The core frequency may change from time to time due to transitions associated with Enhanced Intel SpeedStep Technology or TM2. For this reason this event may have a changing ratio with regards to time.<br>When the core frequency is constant, this event can approximate elapsed time while the core was not in halt state. |
| MSR_PERF_FIXED_CTR2/IA32_PERF_FIXED_CTR2 | 30BH | CPU_CLK_UNHALTED.REF | This event counts the number of reference cycles when the core is not in a halt state and not in a TM stop-clock state. The core enters the halt state when it is running the HLT instruction or the MWAIT instruction. |

**Table 19-18. Fixed-Function Performance Counter and Pre-defined Performance Events (Contd.)**

| Fixed-Function Performance Counter | Address | Event Mask Mnemonic | Description |
|---|---|---|---|
| | | | This event is not affected by core frequency changes (e.g., P states) but counts at the same frequency as the time stamp counter. This event can approximate elapsed time while the core was not in halt state and not in a TM stop-clock state.<br>This event has a constant ratio with the CPU_CLK_UNHALTED.BUS event. |

Table 19-19 lists general-purpose non-architectural performance-monitoring events supported in processors based on Intel® Core™ microarchitecture. For convenience, Table 19-19 also includes architectural events and describes minor model-specific behavior where applicable. Software must use a general-purpose performance counter to count events listed in Table 19-19.

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 03H | 02H | LOAD_BLOCK.STA | Loads blocked by a preceding store with unknown address | This event indicates that loads are blocked by preceding stores. A load is blocked when there is a preceding store to an address that is not yet calculated. The number of events is greater or equal to the number of load operations that were blocked.<br>If the load and the store are always to different addresses, check why the memory disambiguation mechanism is not working. To avoid such blocks, increase the distance between the store and the following load so that the store address is known at the time the load is dispatched. |
| 03H | 04H | LOAD_BLOCK.STD | Loads blocked by a preceding store with unknown data | This event indicates that loads are blocked by preceding stores. A load is blocked when there is a preceding store to the same address and the stored data value is not yet known. The number of events is greater or equal to the number of load operations that were blocked.<br>To avoid such blocks, increase the distance between the store and the dependant load, so that the store data is known at the time the load is dispatched. |
| 03H | 08H | LOAD_BLOCK. OVERLAP_STORE | Loads that partially overlap an earlier store, or 4-Kbyte aliased with a previous store | This event indicates that loads are blocked due to a variety of reasons. Some of the triggers for this event are when a load is blocked by a preceding store, in one of the following:<br>▪ Some of the loaded byte locations are written by the preceding store and some are not.<br>▪ The load is from bytes written by the preceding store, the store is aligned to its size and either:<br>▪ The load's data size is one or two bytes and it is not aligned to the store.<br>▪ The load's data size is of four or eight bytes and the load is misaligned. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| | | | | ▪ The load is from bytes written by the preceding store, the store is misaligned and the load is not aligned on the beginning of the store.<br>▪ The load is split over an eight byte boundary (excluding 16-byte loads).<br>▪ The load and store have the same offset relative to the beginning of different 4-KByte pages. This case is also called 4-KByte aliasing.<br>▪ In all these cases the load is blocked until after the blocking store retires and the stored data is committed to the cache hierarchy. |
| 03H | 10H | LOAD_BLOCK. UNTIL_RETIRE | Loads blocked until retirement | This event indicates that load operations were blocked until retirement. The number of events is greater or equal to the number of load operations that were blocked.<br>This includes mainly uncacheable loads and split loads (loads that cross the cache line boundary) but may include other cases where loads are blocked until retirement. |
| 03H | 20H | LOAD_BLOCK.L1D | Loads blocked by the L1 data cache | This event indicates that loads are blocked due to one or more reasons. Some triggers for this event are:<br>▪ The number of L1 data cache misses exceeds the maximum number of outstanding misses supported by the processor. This includes misses generated as result of demand fetches, software prefetches or hardware prefetches.<br>▪ Cache line split loads.<br>▪ Partial reads, such as reads to un-cacheable memory, I/O instructions and more.<br>▪ A locked load operation is in progress. The number of events is greater or equal to the number of load operations that were blocked. |
| 04H | 01H | SB_DRAIN_ CYCLES | Cycles while stores are blocked due to store buffer drain | This event counts every cycle during which the store buffer is draining. This includes:<br>▪ Serializing operations such as CPUID<br>▪ Synchronizing operations such as XCHG<br>▪ Interrupt acknowledgment<br>▪ Other conditions, such as cache flushing |
| 04H | 02H | STORE_BLOCK. ORDER | Cycles while store is waiting for a preceding store to be globally observed | This event counts the total duration, in number of cycles, which stores are waiting for a preceding stored cache line to be observed by other cores.<br>This situation happens as a result of the strong store ordering behavior, as defined in "Memory Ordering," Chapter 8, *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.<br><br>The stall may occur and be noticeable if there are many cases when a store either misses the L1 data cache or hits a cache line in the Shared state. If the store requires a bus transaction to read the cache line then the stall ends when snoop response for the bus transaction arrives. |
| 04H | 08H | STORE_BLOCK. SNOOP | A store is blocked due to a conflict with an external or internal snoop. | This event counts the number of cycles the store port was used for snooping the L1 data cache and a store was stalled by the snoop. The store is typically resubmitted one cycle later. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 06H | 00H | SEGMENT_REG_ LOADS | Number of segment register loads | This event counts the number of segment register load operations. Instructions that load new values into segment registers cause a penalty.<br>This event indicates performance issues in 16-bit code. If this event occurs frequently, it may be useful to calculate the number of instructions retired per segment register load. If the resulting calculation is low (on average a small number of instructions are executed between segment register loads), then the code's segment register usage should be optimized.<br>As a result of branch misprediction, this event is speculative and may include segment register loads that do not actually occur. However, most segment register loads are internally serialized and such speculative effects are minimized. |
| 07H | 00H | SSE_PRE_EXEC. NTA | Streaming SIMD Extensions (SSE) Prefetch NTA instructions executed | This event counts the number of times the SSE instruction prefetchNTA is executed.<br>This instruction prefetches the data to the L1 data cache. |
| 07H | 01H | SSE_PRE_EXEC.L1 | Streaming SIMD Extensions (SSE) PrefetchT0 instructions executed | This event counts the number of times the SSE instruction prefetchT0 is executed. This instruction prefetches the data to the L1 data cache and L2 cache. |
| 07H | 02H | SSE_PRE_EXEC.L2 | Streaming SIMD Extensions (SSE) PrefetchT1 and PrefetchT2 instructions executed | This event counts the number of times the SSE instructions prefetchT1 and prefetchT2 are executed. These instructions prefetch the data to the L2 cache. |
| 07H | 03H | SSE_PRE_ EXEC.STORES | Streaming SIMD Extensions (SSE) Weakly-ordered store instructions executed | This event counts the number of times SSE non-temporal store instructions are executed. |
| 08H | 01H | DTLB_MISSES. ANY | Memory accesses that missed the DTLB | This event counts the number of Data Table Lookaside Buffer (DTLB) misses. The count includes misses detected as a result of speculative accesses.<br>Typically a high count for this event indicates that the code accesses a large number of data pages. |
| 08H | 02H | DTLB_MISSES .MISS_LD | DTLB misses due to load operations | This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to load operations.<br>This count includes misses detected as a result of speculative accesses. |
| 08H | 04H | DTLB_MISSES.L0_MISS_LD | L0 DTLB misses due to load operations | This event counts the number of level 0 Data Table Lookaside Buffer (DTLB0) misses due to load operations.<br>This count includes misses detected as a result of speculative accesses. Loads that miss that DTLB0 and hit the DTLB1 can incur two-cycle penalty. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 08H | 08H | DTLB_MISSES.<br>MISS_ST | TLB misses due to store operations | This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to store operations.<br><br>This count includes misses detected as a result of speculative accesses. Address translation for store operations is performed in the DTLB1. |
| 09H | 01H | MEMORY_<br>DISAMBIGUATION.RESET | Memory disambiguation reset cycles | This event counts the number of cycles during which memory disambiguation misprediction occurs. As a result the execution pipeline is cleaned and execution of the mispredicted load instruction and all succeeding instructions restarts.<br>This event occurs when the data address accessed by a load instruction, collides infrequently with preceding stores, but usually there is no collision. It happens rarely, and may have a penalty of about 20 cycles. |
| 09H | 02H | MEMORY_DISAMBIGUATIO<br>N.SUCCESS | Number of loads successfully disambiguated. | This event counts the number of load operations that were successfully disambiguated. Loads are preceded by a store with an unknown address, but they are not blocked. |
| 0CH | 01H | PAGE_WALKS<br>.COUNT | Number of page-walks executed | This event counts the number of page-walks executed due to either a DTLB or ITLB miss.<br>The page walk duration, PAGE_WALKS.CYCLES, divided by number of page walks is the average duration of a page walk. The average can hint whether most of the page-walks are satisfied by the caches or cause an L2 cache miss. |
| 0CH | 02H | PAGE_WALKS.<br>CYCLES | Duration of page-walks in core cycles | This event counts the duration of page-walks in core cycles. The paging mode in use typically affects the duration of page walks.<br>Page walk duration divided by number of page walks is the average duration of page-walks. The average can hint at whether most of the page-walks are satisfied by the caches or cause an L2 cache miss. |
| 10H | 00H | FP_COMP_OPS<br>_EXE | Floating point computational micro-ops executed | This event counts the number of floating point computational micro-ops executed.<br>Use IA32_PMC0 only. |
| 11H | 00H | FP_ASSIST | Floating point assists | This event counts the number of floating point operations executed that required micro-code assist intervention. Assists are required in the following cases:<br>▪ Streaming SIMD Extensions (SSE) instructions:<br>▪ Denormal input when the DAZ (Denormals Are Zeros) flag is off<br>▪ Underflow result when the FTZ (Flush To Zero) flag is off<br>▪ X87 instructions:<br>▪ NaN or denormal are loaded to a register or used as input from memory<br>▪ Division by 0<br>▪ Underflow output<br>Use IA32_PMC1 only. |
| 12H | 00H | MUL | Multiply operations executed | This event counts the number of multiply operations executed. This includes integer as well as floating point multiply operations.<br>Use IA32_PMC1 only. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 13H | 00H | DIV | Divide operations executed | This event counts the number of divide operations executed. This includes integer divides, floating point divides and square-root operations executed.<br>Use IA32_PMC1 only. |
| 14H | 00H | CYCLES_DIV _BUSY | Cycles the divider busy | This event counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE.<br>Use IA32_PMC0 only. |
| 18H | 00H | IDLE_DURING _DIV | Cycles the divider is busy and all other execution units are idle. | This event counts the number of cycles the divider is busy (with a divide or a square root operation) and no other execution unit or load operation is in progress.<br>Load operations are assumed to hit the L1 data cache. This event considers only micro-ops dispatched after the divider started operating.<br>Use IA32_PMC0 only. |
| 19H | 00H | DELAYED_ BYPASS.FP | Delayed bypass to FP operation | This event counts the number of times floating point operations use data immediately after the data was generated by a non-floating point execution unit. Such cases result in one penalty cycle due to data bypass between the units.<br>Use IA32_PMC1 only. |
| 19H | 01H | DELAYED_ BYPASS.SIMD | Delayed bypass to SIMD operation | This event counts the number of times SIMD operations use data immediately after the data was generated by a non-SIMD execution unit. Such cases result in one penalty cycle due to data bypass between the units.<br>Use IA32_PMC1 only. |
| 19H | 02H | DELAYED_ BYPASS.LOAD | Delayed bypass to load operation | This event counts the number of delayed bypass penalty cycles that a load operation incurred.<br>When load operations use data immediately after the data was generated by an integer execution unit, they may (pending on certain dynamic internal conditions) incur one penalty cycle due to delayed data bypass between the units.<br>Use IA32_PMC1 only. |
| 21H | See Table 18-2 | L2_ADS.(Core) | Cycles L2 address bus is in use | This event counts the number of cycles the L2 address bus is being used for accesses to the L2 cache or bus queue. It can count occurrences for this core or both cores. |
| 23H | See Table 18-2 | L2_DBUS_BUSY _RD.(Core) | Cycles the L2 transfers data to the core | This event counts the number of cycles during which the L2 data bus is busy transferring data from the L2 cache to the core. It counts for all L1 cache misses (data and instruction) that hit the L2 cache.<br>This event can count occurrences for this core or both cores. |

## Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 24H | Combined mask from Table 18-2 and Table 18-4 | L2_LINES_IN. (Core, Prefetch) | L2 cache misses | This event counts the number of cache lines allocated in the L2 cache. Cache lines are allocated in the L2 cache as a result of requests from the L1 data and instruction caches and the L2 hardware prefetchers to cache lines that are missing in the L2 cache.<br>This event can count occurrences for this core or both cores. It can also count demand requests and L2 hardware prefetch requests together or separately. |
| 25H | See Table 18-2 | L2_M_LINES_IN. (Core) | L2 cache line modifications | This event counts whenever a modified cache line is written back from the L1 data cache to the L2 cache.<br>This event can count occurrences for this core or both cores. |
| 26H | See Table 18-2 and Table 18-4 | L2_LINES_OUT. (Core, Prefetch) | L2 cache lines evicted | This event counts the number of L2 cache lines evicted.<br>This event can count occurrences for this core or both cores. It can also count evictions due to demand requests and L2 hardware prefetch requests together or separately. |
| 27H | See Table 18-2 and Table 18-4 | L2_M_LINES_OUT.(Core, Prefetch) | Modified lines evicted from the L2 cache | This event counts the number of L2 modified cache lines evicted. These lines are written back to memory unless they also exist in a modified-state in one of the L1 data caches.<br>This event can count occurrences for this core or both cores. It can also count evictions due to demand requests and L2 hardware prefetch requests together or separately. |
| 28H | Combined mask from Table 18-2 and Table 18-5 | L2_IFETCH.(Core, Cache Line State) | L2 cacheable instruction fetch requests | This event counts the number of instruction cache line requests from the IFU. It does not include fetch requests from uncacheable memory. It does not include ITLB miss accesses.<br>This event can count occurrences for this core or both cores. It can also count accesses to cache lines at different MESI states. |
| 29H | Combined mask from Table 18-2, Table 18-4, and Table 18-5 | L2_LD.(Core, Prefetch, Cache Line State) | L2 cache reads | This event counts L2 cache read requests coming from the L1 data cache and L2 prefetchers.<br>The event can count occurrences:<br>▪ for this core or both cores<br>▪ due to demand requests and L2 hardware prefetch requests together or separately<br>▪ of accesses to cache lines at different MESI states |
| 2AH | See Table 18-2 and Table 18-5 | L2_ST.(Core, Cache Line State) | L2 store requests | This event counts all store operations that miss the L1 data cache and request the data from the L2 cache.<br>The event can count occurrences for this core or both cores. It can also count accesses to cache lines at different MESI states. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 2BH | See Table 18-2 and Table 18-5 | L2_LOCK.(Core, Cache Line State) | L2 locked accesses | This event counts all locked accesses to cache lines that miss the L1 data cache.<br>The event can count occurrences for this core or both cores. It can also count accesses to cache lines at different MESI states. |
| 2EH | See Table 18-2, Table 18-4, and Table 18-5 | L2_RQSTS.(Core, Prefetch, Cache Line State) | L2 cache requests | This event counts all completed L2 cache requests. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, instruction fetches, and all L2 hardware prefetch requests.<br>This event can count occurrences:<br>▪ for this core or both cores.<br>▪ due to demand requests and L2 hardware prefetch requests together, or separately<br>▪ of accesses to cache lines at different MESI states |
| 2EH | 41H | L2_RQSTS.SELF. DEMAND.I_STATE | L2 cache demand requests from this core that missed the L2 | This event counts all completed L2 cache demand requests from this core that miss the L2 cache. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.<br>This is an architectural performance event. |
| 2EH | 4FH | L2_RQSTS.SELF. DEMAND.MESI | L2 cache demand requests from this core | This event counts all completed L2 cache demand requests from this core. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.<br>This is an architectural performance event. |
| 30H | See Table 18-2, Table 18-4, and Table 18-5 | L2_REJECT_BUSQ.(Core, Prefetch, Cache Line State) | Rejected L2 cache requests | This event indicates that a pending L2 cache request that requires a bus transaction is delayed from moving to the bus queue. Some of the reasons for this event are:<br>▪ The bus queue is full.<br>▪ The bus queue already holds an entry for a cache line in the same set.<br>The number of events is greater or equal to the number of requests that were rejected.<br>▪ for this core or both cores.<br>▪ due to demand requests and L2 hardware prefetch requests together, or separately.<br>▪ of accesses to cache lines at different MESI states. |
| 32H | See Table 18-2 | L2_NO_REQ.(Core) | Cycles no L2 cache requests are pending | This event counts the number of cycles that no L2 cache requests were pending from a core. When using the BOTH_CORE modifier, the event counts only if none of the cores have a pending request. The event counts also when one core is halted and the other is not halted.<br>The event can count occurrences for this core or both cores. |
| 3AH | 00H | EIST_TRANS | Number of Enhanced Intel SpeedStep Technology (EIST) transitions | This event counts the number of transitions that include a frequency change, either with or without voltage change. This includes Enhanced Intel SpeedStep Technology (EIST) and TM2 transitions.<br>The event is incremented only while the counting core is in C0 state. Since transitions to higher-numbered CxE states and TM2 transitions include a frequency change or voltage transition, the event is incremented accordingly. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 3BH | C0H | THERMAL_TRIP | Number of thermal trips | This event counts the number of thermal trips. A thermal trip occurs whenever the processor temperature exceeds the thermal trip threshold temperature.<br>Following a thermal trip, the processor automatically reduces frequency and voltage. The processor checks the temperature every millisecond and returns to normal when the temperature falls below the thermal trip threshold temperature. |
| 3CH | 00H | CPU_CLK_ UNHALTED. CORE_P | Core cycles when core is not halted | This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. This event is a component in many key event ratios.<br>The core frequency may change due to transitions associated with Enhanced Intel SpeedStep Technology or TM2. For this reason, this event may have a changing ratio in regard to time.<br>When the core frequency is constant, this event can give approximate elapsed time while the core not in halt state.<br>This is an architectural performance event. |
| 3CH | 01H | CPU_CLK_ UNHALTED.BUS | Bus cycles when core is not halted | This event counts the number of bus cycles while the core is not in the halt state. This event can give a measurement of the elapsed time while the core was not in the halt state. The core enters the halt state when it is running the HLT instruction.<br>The event also has a constant ratio with CPU_CLK_UNHALTED.REF event, which is the maximum bus to processor frequency ratio.<br>Non-halted bus cycles are a component in many key event ratios. |
| 3CH | 02H | CPU_CLK_ UNHALTED.NO _OTHER | Bus cycles when core is active and the other is halted | This event counts the number of bus cycles during which the core remains non-halted and the other core on the processor is halted.<br>This event can be used to determine the amount of parallelism exploited by an application or a system. Divide this event count by the bus frequency to determine the amount of time that only one core was in use. |
| 40H | See Table 18-5 | L1D_CACHE_LD. (Cache Line State) | L1 cacheable data reads | This event counts the number of data reads from cacheable memory. Locked reads are not counted. |
| 41H | See Table 18-5 | L1D_CACHE_ST. (Cache Line State) | L1 cacheable data writes | This event counts the number of data writes to cacheable memory. Locked writes are not counted. |
| 42H | See Table 18-5 | L1D_CACHE_ LOCK.(Cache Line State) | L1 data cacheable locked reads | This event counts the number of locked data reads from cacheable memory. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 42H | 10H | L1D_CACHE_ LOCK_DURATION | Duration of L1 data cacheable locked operation | This event counts the number of cycles during which any cache line is locked by any locking instruction.<br>Locking happens at retirement and therefore the event does not occur for instructions that are speculatively executed. Locking duration is shorter than locked instruction execution duration. |
| 43H | 01H | L1D_ALL_REF | All references to the L1 data cache | This event counts all references to the L1 data cache, including all loads and stores with any memory types.<br>The event counts memory accesses only when they are actually performed. For example, a load blocked by unknown store address and later performed is only counted once.<br>The event includes non-cacheable accesses, such as I/O accesses. |
| 43H | 02H | L1D_ALL_ CACHE_REF | L1 Data cacheable reads and writes | This event counts the number of data reads and writes from cacheable memory, including locked operations.<br>This event is a sum of:<br>▪ L1D_CACHE_LD.MESI<br>▪ L1D_CACHE_ST.MESI<br>▪ L1D_CACHE_LOCK.MESI |
| 45H | 0FH | L1D_REPL | Cache lines allocated in the L1 data cache | This event counts the number of lines brought into the L1 data cache. |
| 46H | 00H | L1D_M_REPL | Modified cache lines allocated in the L1 data cache | This event counts the number of modified lines brought into the L1 data cache. |
| 47H | 00H | L1D_M_EVICT | Modified cache lines evicted from the L1 data cache | This event counts the number of modified lines evicted from the L1 data cache, whether due to replacement or by snoop HITM intervention. |
| 48H | 00H | L1D_PEND_ MISS | Total number of outstanding L1 data cache misses at any cycle | This event counts the number of outstanding L1 data cache misses at any cycle. An L1 data cache miss is outstanding from the cycle on which the miss is determined until the first chunk of data is available. This event counts:<br>▪ all cacheable demand requests<br>▪ L1 data cache hardware prefetch requests<br>▪ requests to write through memory<br>▪ requests to write combine memory<br>Uncacheable requests are not counted. The count of this event divided by the number of L1 data cache misses, L1D_REPL, is the average duration in core cycles of an L1 data cache miss. |
| 49H | 01H | L1D_SPLIT.LOADS | Cache line split loads from the L1 data cache | This event counts the number of load operations that span two cache lines. Such load operations are also called split loads. Split load operations are executed at retirement. |
| 49H | 02H | L1D_SPLIT. STORES | Cache line split stores to the L1 data cache | This event counts the number of store operations that span two cache lines. |
| 4BH | 00H | SSE_PRE_ MISS.NTA | Streaming SIMD Extensions (SSE) Prefetch NTA instructions missing all cache levels | This event counts the number of times the SSE instructions prefetchNTA were executed and missed all cache levels.<br>Due to speculation an executed instruction might not retire. This instruction prefetches the data to the L1 data cache. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 4BH | 01H | SSE_PRE_ MISS.L1 | Streaming SIMD Extensions (SSE) PrefetchT0 instructions missing all cache levels | This event counts the number of times the SSE instructions prefetchT0 were executed and missed all cache levels.<br>Due to speculation executed instruction might not retire. The prefetchT0 instruction prefetches data to the L2 cache and L1 data cache. |
| 4BH | 02H | SSE_PRE_ MISS.L2 | Streaming SIMD Extensions (SSE) PrefetchT1 and PrefetchT2 instructions missing all cache levels | This event counts the number of times the SSE instructions prefetchT1 and prefetchT2 were executed and missed all cache levels.<br>Due to speculation, an executed instruction might not retire. The prefetchT1 and PrefetchNT2 instructions prefetch data to the L2 cache. |
| 4CH | 00H | LOAD_HIT_PRE | Load operations conflicting with a software prefetch to the same address | This event counts load operations sent to the L1 data cache while a previous Streaming SIMD Extensions (SSE) prefetch instruction to the same cache line has started prefetching but has not yet finished. |
| 4EH | 10H | L1D_PREFETCH. REQUESTS | L1 data cache prefetch requests | This event counts the number of times the L1 data cache requested to prefetch a data cache line. Requests can be rejected when the L2 cache is busy and resubmitted later or lost.<br>All requests are counted, including those that are rejected. |
| 60H | See Table 18-2 and Table 18-3 | BUS_REQUEST_ OUTSTANDING. (Core and Bus Agents) | Outstanding cacheable data read bus requests duration | This event counts the number of pending full cache line read transactions on the bus occurring in each cycle. A read transaction is pending from the cycle it is sent on the bus until the full cache line is received by the processor.<br>The event counts only full-line cacheable read requests from either the L1 data cache or the L2 prefetchers. It does not count Read for Ownership transactions, instruction byte fetch transactions, or any other bus transaction. |
| 61H | See Table 18-3. | BUS_BNR_DRV. (Bus Agents) | Number of Bus Not Ready signals asserted | This event counts the number of Bus Not Ready (BNR) signals that the processor asserts on the bus to suspend additional bus requests by other bus agents.<br>A bus agent asserts the BNR signal when the number of data and snoop transactions is close to the maximum that the bus can handle. To obtain the number of bus cycles during which the BNR signal is asserted, multiply the event count by two.<br>While this signal is asserted, new transactions cannot be submitted on the bus. As a result, transaction latency may have higher impact on program performance. |
| 62H | See Table 18-3 | BUS_DRDY_ CLOCKS.(Bus Agents) | Bus cycles when data is sent on the bus | This event counts the number of bus cycles during which the DRDY (Data Ready) signal is asserted on the bus. The DRDY signal is asserted when data is sent on the bus. With the 'THIS_AGENT' mask this event counts the number of bus cycles during which this agent (the processor) writes data on the bus back to memory or to other bus agents. This includes all explicit and implicit data writebacks, as well as partial writes.<br>With the 'ALL_AGENTS' mask, this event counts the number of bus cycles during which any bus agent sends data on the bus. This includes all data reads and writes on the bus. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 63H | See Table 18-2 and Table 18-3 | BUS_LOCK_ CLOCKS.(Core and Bus Agents) | Bus cycles when a LOCK signal asserted | This event counts the number of bus cycles, during which the LOCK signal is asserted on the bus. A LOCK signal is asserted when there is a locked memory access, due to:<br>▪ uncacheable memory<br>▪ locked operation that spans two cache lines<br>▪ page-walk from an uncacheable page table<br>Bus locks have a very high performance penalty and it is highly recommended to avoid such accesses. |
| 64H | See Table 18-2 | BUS_DATA_ RCV.(Core) | Bus cycles while processor receives data | This event counts the number of bus cycles during which the processor is busy receiving data. |
| 65H | See Table 18-2 and Table 18-3 | BUS_TRANS_BRD.(Core and Bus Agents) | Burst read bus transactions | This event counts the number of burst read transactions including:<br>▪ L1 data cache read misses (and L1 data cache hardware prefetches)<br>▪ L2 hardware prefetches by the DPL and L2 streamer<br>▪ IFU read misses of cacheable lines.<br>It does not include RFO transactions. |
| 66H | See Table 18-2 and Table 18-3. | BUS_TRANS_RFO.(Core and Bus Agents) | RFO bus transactions | This event counts the number of Read For Ownership (RFO) bus transactions, due to store operations that miss the L1 data cache and the L2 cache. It also counts RFO bus transactions due to locked operations. |
| 67H | See Table 18-2 and Table 18-3. | BUS_TRANS_WB. (Core and Bus Agents) | Explicit writeback bus transactions | This event counts all explicit writeback bus transactions due to dirty line evictions. It does not count implicit writebacks due to invalidation by a snoop request. |
| 68H | See Table 18-2 and Table 18-3 | BUS_TRANS_ IFETCH.(Core and Bus Agents) | Instruction-fetch bus transactions | This event counts all instruction fetch full cache line bus transactions. |
| 69H | See Table 18-2 and Table 18-3 | BUS_TRANS_ INVAL.(Core and Bus Agents) | Invalidate bus transactions | This event counts all invalidate transactions. Invalidate transactions are generated when:<br>▪ A store operation hits a shared line in the L2 cache.<br>▪ A full cache line write misses the L2 cache or hits a shared line in the L2 cache. |
| 6AH | See Table 18-2 and Table 18-3 | BUS_TRANS_ PWR.(Core and Bus Agents) | Partial write bus transaction | This event counts partial write bus transactions. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 6BH | See Table 18-2 and Table 18-3 | BUS_TRANS _P.(Core and Bus Agents) | Partial bus transactions | This event counts all (read and write) partial bus transactions. |
| 6CH | See Table 18-2 and Table 18-3 | BUS_TRANS_IO.(Core and Bus Agents) | IO bus transactions | This event counts the number of completed I/O bus transactions as a result of IN and OUT instructions. The count does not include memory mapped IO. |
| 6DH | See Table 18-2 and Table 18-3 | BUS_TRANS_ DEF.(Core and Bus Agents) | Deferred bus transactions | This event counts the number of deferred transactions. |
| 6EH | See Table 18-2 and Table 18-3 | BUS_TRANS_ BURST.(Core and Bus Agents) | Burst (full cache-line) bus transactions | This event counts burst (full cache line) transactions including:<br>▪ Burst reads<br>▪ RFOs<br>▪ Explicit writebacks<br>▪ Write combine lines |
| 6FH | See Table 18-2 and Table 18-3 | BUS_TRANS_ MEM.(Core and Bus Agents) | Memory bus transactions | This event counts all memory bus transactions including:<br>▪ Burst transactions<br>▪ Partial reads and writes - invalidate transactions<br>The BUS_TRANS_MEM count is the sum of BUS_TRANS_BURST, BUS_TRANS_P and BUS_TRANS_IVAL. |
| 70H | See Table 18-2 and Table 18-3 | BUS_TRANS_ ANY.(Core and Bus Agents) | All bus transactions | This event counts all bus transactions. This includes:<br>▪ Memory transactions<br>▪ IO transactions (non memory-mapped)<br>▪ Deferred transaction completion<br>▪ Other less frequent transactions, such as interrupts |
| 77H | See Table 18-2 and Table 18-6 | EXT_SNOOP. (Bus Agents, Snoop Response) | External snoops | This event counts the snoop responses to bus transactions. Responses can be counted separately by type and by bus agent.<br>With the 'THIS_AGENT' mask, the event counts snoop responses from this processor to bus transactions sent by this processor. With the 'ALL_AGENTS' mask the event counts all snoop responses seen on the bus. |
| 78H | See Table 18-2 and Table 18-7 | CMP_SNOOP.(Core, Snoop Type) | L1 data cache snooped by other core | This event counts the number of times the L1 data cache is snooped for a cache line that is needed by the other core in the same processor. The cache line is either missing in the L1 instruction or data caches of the other core, or is available for reading only and the other core wishes to write the cache line. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| | | | | The snoop operation may change the cache line state. If the other core issued a read request that hit this core in E state, typically the state changes to S state in this core. If the other core issued a read for ownership request (due a write miss or hit to S state) that hits this core's cache line in E or S state, this typically results in invalidation of the cache line in this core. If the snoop hits a line in M state, the state is changed at a later opportunity.<br>These snoops are performed through the L1 data cache store port. Therefore, frequent snoops may conflict with extensive stores to the L1 data cache, which may increase store latency and impact performance. |
| 7AH | See Table 18-3 | BUS_HIT_DRV.<br>(Bus Agents) | HIT signal asserted | This event counts the number of bus cycles during which the processor drives the HIT# pin to signal HIT snoop response. |
| 7BH | See Table 18-3 | BUS_HITM_DRV.<br>(Bus Agents) | HITM signal asserted | This event counts the number of bus cycles during which the processor drives the HITM# pin to signal HITM snoop response. |
| 7DH | See Table 18-2 | BUSQ_EMPTY.<br>(Core) | Bus queue empty | This event counts the number of cycles during which the core did not have any pending transactions in the bus queue. It also counts when the core is halted and the other core is not halted.<br>This event can count occurrences for this core or both cores. |
| 7EH | See Table 18-2 and Table 18-3 | SNOOP_STALL_ DRV.(Core and Bus Agents) | Bus stalled for snoops | This event counts the number of times that the bus snoop stall signal is asserted. To obtain the number of bus cycles during which snoops on the bus are prohibited, multiply the event count by two.<br>During the snoop stall cycles, no new bus transactions requiring a snoop response can be initiated on the bus. A bus agent asserts a snoop stall signal if it cannot response to a snoop request within three bus cycles. |
| 7FH | See Table 18-2 | BUS_IO_WAIT.<br>(Core) | IO requests waiting in the bus queue | This event counts the number of core cycles during which IO requests wait in the bus queue. With the SELF modifier this event counts IO requests per core.<br>With the BOTH_CORE modifier, this event increments by one for any cycle for which there is a request from either core. |
| 80H | 00H | L1I_READS | Instruction fetches | This event counts all instruction fetches, including uncacheable fetches that bypass the Instruction Fetch Unit (IFU). |
| 81H | 00H | L1I_MISSES | Instruction Fetch Unit misses | This event counts all instruction fetches that miss the Instruction Fetch Unit (IFU) or produce memory requests. This includes uncacheable fetches.<br>An instruction fetch miss is counted only once and not once for every cycle it is outstanding. |
| 82H | 02H | ITLB.SMALL_MISS | ITLB small page misses | This event counts the number of instruction fetches from small pages that miss the ITLB. |
| 82H | 10H | ITLB.LARGE_MISS | ITLB large page misses | This event counts the number of instruction fetches from large pages that miss the ITLB. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 82H | 40H | ITLB.FLUSH | ITLB flushes | This event counts the number of ITLB flushes. This usually happens upon CR3 or CR0 writes, which are executed by the operating system during process switches. |
| 82H | 12H | ITLB.MISSES | ITLB misses | This event counts the number of instruction fetches from either small or large pages that miss the ITLB. |
| 83H | 02H | INST_QUEUE.FULL | Cycles during which the instruction queue is full | This event counts the number of cycles during which the instruction queue is full. In this situation, the core front-end stops fetching more instructions. This is an indication of very long stalls in the back-end pipeline stages. |
| 86H | 00H | CYCLES_L1I_ MEM_STALLED | Cycles during which instruction fetches stalled | This event counts the number of cycles for which an instruction fetch stalls, including stalls due to any of the following reasons:<br>▪ instruction Fetch Unit cache misses<br>▪ instruction TLB misses<br>▪ instruction TLB faults |
| 87H | 00H | ILD_STALL | Instruction Length Decoder stall cycles due to a length changing prefix | This event counts the number of cycles during which the instruction length decoder uses the slow length decoder. Usually, instruction length decoding is done in one cycle. When the slow decoder is used, instruction decoding requires 6 cycles.<br>The slow decoder is used in the following cases:<br>▪ operand override prefix (66H) preceding an instruction with immediate data<br>▪ address override prefix (67H) preceding an instruction with a modr/m in real, big real, 16-bit protected or 32-bit protected modes<br>To avoid instruction length decoding stalls, generate code using imm8 or imm32 values instead of imm16 values. If you must use an imm16 value, store the value in a register using "mov reg, imm32" and use the register format of the instruction. |
| 88H | 00H | BR_INST_EXEC | Branch instructions executed | This event counts all executed branches (not necessarily retired). This includes only instructions and not micro-op branches.<br>Frequent branching is not necessarily a major performance issue. However frequent branch mispredictions may be a problem. |
| 89H | 00H | BR_MISSP_EXEC | Mispredicted branch instructions executed | This event counts the number of mispredicted branch instructions that were executed. |
| 8AH | 00H | BR_BAC_ MISSP_EXEC | Branch instructions mispredicted at decoding | This event counts the number of branch instructions that were mispredicted at decoding. |
| 8BH | 00H | BR_CND_EXEC | Conditional branch instructions executed. | This event counts the number of conditional branch instructions executed, but not necessarily retired. |
| 8CH | 00H | BR_CND_ MISSP_EXEC | Mispredicted conditional branch instructions executed | This event counts the number of mispredicted conditional branch instructions that were executed. |
| 8DH | 00H | BR_IND_EXEC | Indirect branch instructions executed | This event counts the number of indirect branch instructions that were executed. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 8EH | 00H | BR_IND_MISSP _EXEC | Mispredicted indirect branch instructions executed | This event counts the number of mispredicted indirect branch instructions that were executed. |
| 8FH | 00H | BR_RET_EXEC | RET instructions executed | This event counts the number of RET instructions that were executed. |
| 90H | 00H | BR_RET_ MISSP_EXEC | Mispredicted RET instructions executed | This event counts the number of mispredicted RET instructions that were executed. |
| 91H | 00H | BR_RET_BAC_ MISSP_EXEC | RET instructions executed mispredicted at decoding | This event counts the number of RET instructions that were executed and were mispredicted at decoding. |
| 92H | 00H | BR_CALL_EXEC | CALL instructions executed | This event counts the number of CALL instructions executed. |
| 93H | 00H | BR_CALL_ MISSP_EXEC | Mispredicted CALL instructions executed | This event counts the number of mispredicted CALL instructions that were executed. |
| 94H | 00H | BR_IND_CALL_ EXEC | Indirect CALL instructions executed | This event counts the number of indirect CALL instructions that were executed. |
| 97H | 00H | BR_TKN_ BUBBLE_1 | Branch predicted taken with bubble 1 | The events BR_TKN_BUBBLE_1 and BR_TKN_BUBBLE_2 together count the number of times a taken branch prediction incurred a one-cycle penalty. The penalty incurs when:<br>▪ Too many taken branches are placed together. To avoid this, unroll loops and add a non-taken branch in the middle of the taken sequence.<br>▪ The branch target is unaligned. To avoid this, align the branch target. |
| 98H | 00H | BR_TKN_ BUBBLE_2 | Branch predicted taken with bubble 2 | The events BR_TKN_BUBBLE_1 and BR_TKN_BUBBLE_2 together count the number of times a taken branch prediction incurred a one-cycle penalty. The penalty incurs when:<br>▪ Too many taken branches are placed together. To avoid this, unroll loops and add a non-taken branch in the middle of the taken sequence.<br>▪ The branch target is unaligned. To avoid this, align the branch target. |
| A0H | 00H | RS_UOPS_ DISPATCHED | Micro-ops dispatched for execution | This event counts the number of micro-ops dispatched for execution. Up to six micro-ops can be dispatched in each cycle. |
| A1H | 01H | RS_UOPS_ DISPATCHED.PORT0 | Cycles micro-ops dispatched for execution on port 0 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Issue Ports are described in *Intel® 64 and IA-32 Architectures Optimization Reference Manual*. Use IA32_PMC0 only. |
| A1H | 02H | RS_UOPS_ DISPATCHED.PORT1 | Cycles micro-ops dispatched for execution on port 1 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only. |
| A1H | 04H | RS_UOPS_ DISPATCHED.PORT2 | Cycles micro-ops dispatched for execution on port 2 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| A1H | 08H | RS_UOPS_ DISPATCHED.PORT3 | Cycles micro-ops dispatched for execution on port 3 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only. |
| A1H | 10H | RS_UOPS_ DISPATCHED.PORT4 | Cycles micro-ops dispatched for execution on port 4 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only. |
| A1H | 20H | RS_UOPS_ DISPATCHED.PORT5 | Cycles micro-ops dispatched for execution on port 5 | This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only. |
| AAH | 01H | MACRO_INSTS. DECODED | Instructions decoded | This event counts the number of instructions decoded (but not necessarily executed or retired). |
| AAH | 08H | MACRO_INSTS. CISC_DECODED | CISC Instructions decoded | This event counts the number of complex instructions decoded. Complex instructions usually have more than four micro-ops. Only one complex instruction can be decoded at a time. |
| ABH | 01H | ESP.SYNCH | ESP register content synchron-ization | This event counts the number of times that the ESP register is explicitly used in the address expression of a load or store operation, after it is implicitly used, for example by a push or a pop instruction.<br>ESP synch micro-op uses resources from the rename pipe-stage and up to retirement. The expected ratio of this event divided by the number of ESP implicit changes is 0,2. If the ratio is higher, consider rearranging your code to avoid ESP synchronization events. |
| ABH | 02H | ESP.ADDITIONS | ESP register automatic additions | This event counts the number of ESP additions performed automatically by the decoder. A high count of this event is good, since each automatic addition performed by the decoder saves a micro-op from the execution units.<br>To maximize the number of ESP additions performed automatically by the decoder, choose instructions that implicitly use the ESP, such as PUSH, POP, CALL, and RET instructions whenever possible. |
| B0H | 00H | SIMD_UOPS_EXEC | SIMD micro-ops executed (excluding stores) | This event counts all the SIMD micro-ops executed. It does not count MOVQ and MOVD stores from register to memory. |
| B1H | 00H | SIMD_SAT_UOP_ EXEC | SIMD saturated arithmetic micro-ops executed | This event counts the number of SIMD saturated arithmetic micro-ops executed. |
| B3H | 01H | SIMD_UOP_ TYPE_EXEC.MUL | SIMD packed multiply micro-ops executed | This event counts the number of SIMD packed multiply micro-ops executed. |
| B3H | 02H | SIMD_UOP_TYPE_EXEC.SHI FT | SIMD packed shift micro-ops executed | This event counts the number of SIMD packed shift micro-ops executed. |
| B3H | 04H | SIMD_UOP_TYPE_EXEC.PA CK | SIMD pack micro-ops executed | This event counts the number of SIMD pack micro-ops executed. |
| B3H | 08H | SIMD_UOP_TYPE_EXEC.UN PACK | SIMD unpack micro-ops executed | This event counts the number of SIMD unpack micro-ops executed. |
| B3H | 10H | SIMD_UOP_TYPE_EXEC.LO GICAL | SIMD packed logical micro-ops executed | This event counts the number of SIMD packed logical micro-ops executed. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| B3H | 20H | SIMD_UOP_TYPE_EXEC.ARITHMETIC | SIMD packed arithmetic micro-ops executed | This event counts the number of SIMD packed arithmetic micro-ops executed. |
| C0H | 00H | INST_RETIRED.ANY_P | Instructions retired | This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continue counting during hardware interrupts, traps, and inside interrupt handlers.<br>INST_RETIRED.ANY_P is an architectural performance event. |
| C0H | 01H | INST_RETIRED.LOADS | Instructions retired, which contain a load | This event counts the number of instructions retired that contain a load operation. |
| C0H | 02H | INST_RETIRED.STORES | Instructions retired, which contain a store | This event counts the number of instructions retired that contain a store operation. |
| C0H | 04H | INST_RETIRED.OTHER | Instructions retired, with no load or store operation | This event counts the number of instructions retired that do not contain a load or a store operation. |
| C1H | 01H | X87_OPS_RETIRED.FXCH | FXCH instructions retired | This event counts the number of FXCH instructions retired. Modern compilers generate more efficient code and are less likely to use this instruction. If you obtain a high count for this event consider recompiling the code. |
| C1H | FEH | X87_OPS_RETIRED.ANY | Retired floating-point computational operations (precise event) | This event counts the number of floating-point computational operations retired. It counts:<br>▪ floating point computational operations executed by the assist handler<br>▪ sub-operations of complex floating-point instructions like transcendental instructions<br>This event does not count:<br>▪ floating-point computational operations that cause traps or assists.<br>▪ floating-point loads and stores.<br>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event. |
| C2H | 01H | UOPS_RETIRED.LD_IND_BR | Fused load+op or load+indirect branch retired | This event counts the number of retired micro-ops that fused a load with another operation. This includes:<br>▪ Fusion of a load and an arithmetic operation, such as with the following instruction: ADD EAX, [EBX] where the content of the memory location specified by EBX register is loaded, added to EXA register, and the result is stored in EAX.<br>▪ Fusion of a load and a branch in an indirect branch operation, such as with the following instructions:<br>▪ JMP [RDI+200]<br>▪ RET<br>▪ Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code is using the processor resources effectively. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| C2H | 02H | UOPS_RETIRED. STD_STA | Fused store address + data retired | This event counts the number of store address calculations that are fused with store data emission into one micro-op. Traditionally, each store operation required two micro-ops.<br>This event counts fusion of retired micro-ops only. Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code is using the processor resources effectively. |
| C2H | 04H | UOPS_RETIRED. MACRO_FUSION | Retired instruction pairs fused into one micro-op | This event counts the number of times CMP or TEST instructions were fused with a conditional branch instruction into one micro-op. It counts fusion by retired micro-ops only.<br>Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code uses the processor resources more effectively. |
| C2H | 07H | UOPS_RETIRED. FUSED | Fused micro-ops retired | This event counts the total number of retired fused micro-ops. The counts include the following fusion types:<br>▪ Fusion of load operation with an arithmetic operation or with an indirect branch (counted by event UOPS_RETIRED.LD_IND_BR)<br>▪ Fusion of store address and data (counted by event UOPS_RETIRED.STD_STA)<br>▪ Fusion of CMP or TEST instruction with a conditional branch instruction (counted by event UOPS_RETIRED.MACRO_FUSION)<br>Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code is using the processor resources effectively. |
| C2H | 08H | UOPS_RETIRED. NON_FUSED | Non-fused micro-ops retired | This event counts the number of micro-ops retired that were not fused. |
| C2H | 0FH | UOPS_RETIRED. ANY | Micro-ops retired | This event counts the number of micro-ops retired. The processor decodes complex macro instructions into a sequence of simpler micro-ops. Most instructions are composed of one or two micro-ops.<br>Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. In some cases micro-op sequences are fused or whole instructions are fused into one micro-op.<br>See other UOPS_RETIRED events for differentiating retired fused and non-fused micro-ops. |
| C3H | 01H | MACHINE_ NUKES.SMC | Self-Modifying Code detected | This event counts the number of times that a program writes to a code section. Self-modifying code causes a sever penalty in all Intel 64 and IA-32 processors. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| C3H | 04H | MACHINE_NUKES.MEM_ORDER | Execution pipeline restart due to memory ordering conflict or memory disambiguation misprediction | This event counts the number of times the pipeline is restarted due to either multi-threaded memory ordering conflicts or memory disambiguation misprediction.<br>A multi-threaded memory ordering conflict occurs when a store, which is executed in another core, hits a load that is executed out of order in this core but not yet retired. As a result, the load needs to be restarted to satisfy the memory ordering model.<br>See Chapter 8, "Multiple-Processor Management" in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.<br>To count memory disambiguation mispredictions, use the event MEMORY_DISAMBIGUATION.RESET. |
| C4H | 00H | BR_INST_RETIRED.ANY | Retired branch instructions | This event counts the number of branch instructions retired. This is an architectural performance event. |
| C4H | 01H | BR_INST_RETIRED.PRED_NOT_TAKEN | Retired branch instructions that were predicted not-taken | This event counts the number of branch instructions retired that were correctly predicted to be not-taken. |
| C4H | 02H | BR_INST_RETIRED.MISPRED_NOT_TAKEN | Retired branch instructions that were mispredicted not-taken | This event counts the number of branch instructions retired that were mispredicted and not-taken. |
| C4H | 04H | BR_INST_RETIRED.PRED_TAKEN | Retired branch instructions that were predicted taken | This event counts the number of branch instructions retired that were correctly predicted to be taken. |
| C4H | 08H | BR_INST_RETIRED.MISPRED_TAKEN | Retired branch instructions that were mispredicted taken | This event counts the number of branch instructions retired that were mispredicted and taken. |
| C4H | 0CH | BR_INST_RETIRED.TAKEN | Retired taken branch instructions | This event counts the number of branches retired that were taken. |
| C5H | 00H | BR_INST_RETIRED.MISPRED | Retired mispredicted branch instructions. (precise event) | This event counts the number of retired branch instructions that were mispredicted by the processor. A branch misprediction occurs when the processor predicts that the branch would be taken, but it is not, or vice-versa.<br>This is an architectural performance event. |
| C6H | 01H | CYCLES_INT_MASKED | Cycles during which interrupts are disabled | This event counts the number of cycles during which interrupts are disabled. |
| C6H | 02H | CYCLES_INT_PENDING_AND_MASKED | Cycles during which interrupts are pending and disabled | This event counts the number of cycles during which there are pending interrupts but interrupts are disabled. |
| C7H | 01H | SIMD_INST_RETIRED.PACKED_SINGLE | Retired SSE packed-single instructions | This event counts the number of SSE packed-single instructions retired. |
| C7H | 02H | SIMD_INST_RETIRED.SCALAR_SINGLE | Retired SSE scalar-single instructions | This event counts the number of SSE scalar-single instructions retired. |
| C7H | 04H | SIMD_INST_RETIRED.PACKED_DOUBLE | Retired SSE2 packed-double instructions | This event counts the number of SSE2 packed-double instructions retired. |
| C7H | 08H | SIMD_INST_RETIRED.SCALAR_DOUBLE | Retired SSE2 scalar-double instructions | This event counts the number of SSE2 scalar-double instructions retired. |

Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| C7H | 10H | SIMD_INST_ RETIRED.VECTOR | Retired SSE2 vector integer instructions | This event counts the number of SSE2 vector integer instructions retired. |
| C7H | 1FH | SIMD_INST_ RETIRED.ANY | Retired Streaming SIMD instructions (precise event) | This event counts the overall number of retired SIMD instructions that use XMM registers. To count each type of SIMD instruction separately, use the following events:<br>▪ SIMD_INST_RETIRED.PACKED_SINGLE<br>▪ SIMD_INST_RETIRED.SCALAR_SINGLE<br>▪ SIMD_INST_RETIRED.PACKED_DOUBLE<br>▪ SIMD_INST_RETIRED.SCALAR_DOUBLE<br>▪ and SIMD_INST_RETIRED.VECTOR<br>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event. |
| C8H | 00H | HW_INT_RCV | Hardware interrupts received | This event counts the number of hardware interrupts received by the processor. |
| C9H | 00H | ITLB_MISS_ RETIRED | Retired instructions that missed the ITLB | This event counts the number of retired instructions that missed the ITLB when they were fetched. |
| CAH | 01H | SIMD_COMP_ INST_RETIRED. PACKED_SINGLE | Retired computational SSE packed-single instructions | This event counts the number of computational SSE packed-single instructions retired. Computational instructions perform arithmetic computations (for example: add, multiply and divide).<br>Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |
| CAH | 02H | SIMD_COMP_ INST_RETIRED. SCALAR_SINGLE | Retired computational SSE scalar-single instructions | This event counts the number of computational SSE scalar-single instructions retired. Computational instructions perform arithmetic computations (for example: add, multiply and divide).<br>Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |
| CAH | 04H | SIMD_COMP_ INST_RETIRED. PACKED_DOUBLE | Retired computational SSE2 packed-double instructions | This event counts the number of computational SSE2 packed-double instructions retired. Computational instructions perform arithmetic computations (for example: add, multiply and divide).<br>Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |
| CAH | 08H | SIMD_COMP_INST_RETIRE D.SCALAR_DOUBLE | Retired computational SSE2 scalar-double instructions | This event counts the number of computational SSE2 scalar-double instructions retired. Computational instructions perform arithmetic computations (for example: add, multiply and divide).<br>Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| CBH | 01H | MEM_LOAD_ RETIRED.L1D _MISS | Retired loads that miss the L1 data cache (precise event) | This event counts the number of retired load operations that missed the L1 data cache. This includes loads from cache lines that are currently being fetched, due to a previous L1 data cache miss to the same cache line.<br>This event counts loads from cacheable memory only. The event does not count loads by software prefetches.<br>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.<br>Use IA32_PMC0 only. |
| CBH | 02H | MEM_LOAD_ RETIRED.L1D_ LINE_MISS | L1 data cache line missed by retired loads (precise event) | This event counts the number of load operations that miss the L1 data cache and send a request to the L2 cache to fetch the missing cache line. That is the missing cache line fetching has not yet started.<br>The event count is equal to the number of cache lines fetched from the L2 cache by retired loads.<br>This event counts loads from cacheable memory only. The event does not count loads by software prefetches.<br>The event might not be counted if the load is blocked (see LOAD_BLOCK events).<br>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.<br>Use IA32_PMC0 only. |
| CBH | 04H | MEM_LOAD_ RETIRED.L2_MISS | Retired loads that miss the L2 cache (precise event) | This event counts the number of retired load operations that missed the L2 cache.<br>This event counts loads from cacheable memory only. It does not count loads by software prefetches.<br>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.<br>Use IA32_PMC0 only. |

Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| CBH | 08H | MEM_LOAD_ RETIRED.L2_LINE_MISS | L2 cache line missed by retired loads (precise event) | This event counts the number of load operations that miss the L2 cache and result in a bus request to fetch the missing cache line. That is the missing cache line fetching has not yet started.<br>This event count is equal to the number of cache lines fetched from memory by retired loads.<br>This event counts loads from cacheable memory only. The event does not count loads by software prefetches.<br>The event might not be counted if the load is blocked (see LOAD_BLOCK events).<br>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.<br>Use IA32_PMC0 only. |
| CBH | 10H | MEM_LOAD_ RETIRED.DTLB_ MISS | Retired loads that miss the DTLB (precise event) | This event counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault.<br>This event counts loads from cacheable memory only. The event does not count loads by software prefetches.<br>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.<br>Use IA32_PMC0 only. |
| CCH | 01H | FP_MMX_TRANS_TO_MMX | Transitions from Floating Point to MMX Instructions | This event counts the first MMX instructions following a floating-point instruction. Use this event to estimate the penalties for the transitions between floating-point and MMX states. |
| CCH | 02H | FP_MMX_TRANS_TO_FP | Transitions from MMX Instructions to Floating Point Instructions | This event counts the first floating-point instructions following any MMX instruction. Use this event to estimate the penalties for the transitions between floating-point and MMX states. |
| CDH | 00H | SIMD_ASSIST | SIMD assists invoked | This event counts the number of SIMD assists invoked. SIMD assists are invoked when an EMMS instruction is executed, changing the MMX state in the floating point stack. |
| CEH | 00H | SIMD_INSTR_ RETIRED | SIMD Instructions retired | This event counts the number of retired SIMD instructions that use MMX registers. |
| CFH | 00H | SIMD_SAT_INSTR_RETIRED | Saturated arithmetic instructions retired | This event counts the number of saturated arithmetic SIMD instructions that retired. |
| D2H | 01H | RAT_STALLS. ROB_READ_PORT | ROB read port stalls cycles | This event counts the number of cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the out-of-order pipeline.<br>Note that, at this stage in the pipeline, additional stalls may occur at the same cycle and prevent the stalled micro-ops from entering the pipe. In such a case, micro-ops retry entering the execution pipe in the next cycle and the ROB-read-port stall is counted again. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| D2H | 02H | RAT_STALLS. PARTIAL_CYCLES | Partial register stall cycles | This event counts the number of cycles instruction execution latency became longer than the defined latency because the instruction uses a register that was partially written by previous instructions. |
| D2H | 04H | RAT_STALLS. FLAGS | Flag stall cycles | This event counts the number of cycles during which execution stalled due to several reasons, one of which is a partial flag register stall.<br>A partial register stall may occur when two conditions are met:<br>▪ an instruction modifies some, but not all, of the flags in the flag register<br>▪ the next instruction, which depends on flags, depends on flags that were not modified by this instruction |
| D2H | 08H | RAT_STALLS. FPSW | FPU status word stall | This event indicates that the FPU status word (FPSW) is written. To obtain the number of times the FPSW is written divide the event count by 2.<br>The FPSW is written by instructions with long latency; a small count may indicate a high penalty. |
| D2H | 0FH | RAT_STALLS. ANY | All RAT stall cycles | This event counts the number of stall cycles due to conditions described by:<br>▪ RAT_STALLS.ROB_READ_PORT<br>▪ RAT_STALLS.PARTIAL<br>▪ RAT_STALLS.FLAGS<br>▪ RAT_STALLS.FPSW. |
| D4H | 01H | SEG_RENAME_ STALLS.ES | Segment rename stalls - ES | This event counts the number of stalls due to the lack of renaming resources for the ES segment register. If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires. |
| D4H | 02H | SEG_RENAME_ STALLS.DS | Segment rename stalls - DS | This event counts the number of stalls due to the lack of renaming resources for the DS segment register. If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires. |
| D4H | 04H | SEG_RENAME_ STALLS.FS | Segment rename stalls - FS | This event counts the number of stalls due to the lack of renaming resources for the FS segment register.<br>If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires. |
| D4H | 08H | SEG_RENAME_ STALLS.GS | Segment rename stalls - GS | This event counts the number of stalls due to the lack of renaming resources for the GS segment register.<br>If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires. |
| D4H | 0FH | SEG_RENAME_ STALLS.ANY | Any (ES/DS/FS/GS) segment rename stall | This event counts the number of stalls due to the lack of renaming resources for the ES, DS, FS, and GS segment registers.<br>If a segment is renamed but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires. |

Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| D5H | 01H | SEG_REG_ RENAMES.ES | Segment renames - ES | This event counts the number of times the ES segment register is renamed. |
| D5H | 02H | SEG_REG_ RENAMES.DS | Segment renames - DS | This event counts the number of times the DS segment register is renamed. |
| D5H | 04H | SEG_REG_ RENAMES.FS | Segment renames - FS | This event counts the number of times the FS segment register is renamed. |
| D5H | 08H | SEG_REG_ RENAMES.GS | Segment renames - GS | This event counts the number of times the GS segment register is renamed. |
| D5H | 0FH | SEG_REG_ RENAMES.ANY | Any (ES/DS/FS/GS) segment rename | This event counts the number of times any of the four segment registers (ES/DS/FS/GS) is renamed. |
| DCH | 01H | RESOURCE_ STALLS.ROB_FULL | Cycles during which the ROB full | This event counts the number of cycles when the number of instructions in the pipeline waiting for retirement reaches the limit the processor can handle.<br>A high count for this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, and other instructions that depend on these cannot execute until the former instructions complete execution). In this situation new instructions can not enter the pipe and start execution. |
| DCH | 02H | RESOURCE_ STALLS.RS_FULL | Cycles during which the RS full | This event counts the number of cycles when the number of instructions in the pipeline waiting for execution reaches the limit the processor can handle.<br>A high count of this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, and other instructions that depend on these cannot execute until the former instructions complete execution). In this situation new instructions can not enter the pipe and start execution. |
| DCH | 04 | RESOURCE_ STALLS.LD_ST | Cycles during which the pipeline has exceeded load or store limit or waiting to commit all stores | This event counts the number of cycles while resource-related stalls occur due to:<br>▪ The number of load instructions in the pipeline reached the limit the processor can handle. The stall ends when a loading instruction retires.<br>▪ The number of store instructions in the pipeline reached the limit the processor can handle. The stall ends when a storing instruction commits its data to the cache or memory.<br>▪ There is an instruction in the pipe that can be executed only when all previous stores complete and their data is committed in the caches or memory. For example, the SFENCE and MFENCE instructions require this behavior. |
| DCH | 08H | RESOURCE_ STALLS.FPCW | Cycles stalled due to FPU control word write | This event counts the number of cycles while execution was stalled due to writing the floating-point unit (FPU) control word. |
| DCH | 10H | RESOURCE_ STALLS.BR_MISS_CLEAR | Cycles stalled due to branch misprediction | This event counts the number of cycles after a branch misprediction is detected at execution until the branch and all older micro-ops retire. During this time new micro-ops cannot enter the out-of-order pipeline. |

**Table 19-19. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

| Event Num | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| DCH | 1FH | RESOURCE_ STALLS.ANY | Resource related stalls | This event counts the number of cycles while resource-related stalls occurs for any conditions described by the following events:<br>▪ RESOURCE_STALLS.ROB_FULL<br>▪ RESOURCE_STALLS.RS_FULL<br>▪ RESOURCE_STALLS.LD_ST<br>▪ RESOURCE_STALLS.FPCW<br>▪ RESOURCE_STALLS.BR_MISS_CLEAR |
| E0H | 00H | BR_INST_ DECODED | Branch instructions decoded | This event counts the number of branch instructions decoded. |
| E4H | 00H | BOGUS_BR | Bogus branches | This event counts the number of byte sequences that were mistakenly detected as taken branch instructions.<br>This results in a BACLEAR event. This occurs mainly after task switches. |
| E6H | 00H | BACLEARS | BACLEARS asserted | This event counts the number of times the front end is resteered, mainly when the BPU cannot provide a correct prediction and this is corrected by other branch handling mechanisms at the front and. This can occur if the code has many branches such that they cannot be consumed by the BPU.<br>Each BACLEAR asserted costs approximately 7 cycles of instruction fetch. The effect on total execution time depends on the surrounding code. |
| F0 | 00H | PREF_RQSTS_UP | Upward prefetches issued from DPL | This event counts the number of upward prefetches issued from the Data Prefetch Logic (DPL) to the L2 cache. A prefetch request issued to the L2 cache cannot be cancelled and the requested cache line is fetched to the L2 cache. |
| F8 | 00H | PREF_RQSTS_DN | Downward prefetches issued from DPL. | This event counts the number of downward prefetches issued from the Data Prefetch Logic (DPL) to the L2 cache. A prefetch request issued to the L2 cache cannot be cancelled and the requested cache line is fetched to the L2 cache. |

## 19.10 PERFORMANCE MONITORING EVENTS FOR PROCESSORS BASED ON THE SILVERMONT MICROARCHITECTURE

Processors based on the Silvermont microarchitecture support the architectural performance-monitoring events listed in Table 19-1 and fixed-function performance events using fixed counter. In addition, they also support the following non-architectural performance-monitoring events listed in Table 19-20.

**Table 19-20. Performance Events for Silvermont Microarchitecture**

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 03H | 01H | REHABQ.LD_BLOCK_ST_FORWARD | Loads blocked due to store forward restriction | This event counts the number of retired loads that were prohibited from receiving forwarded data from the store because of address mismatch. |
| 03H | 02H | REHABQ.LD_BLOCK_STD_NOTREADY | Loads blocked due to store data not ready | This event counts the cases where a forward was technically possible, but did not occur because the store data was not available at the right time |
| 03H | 04H | REHABQ.ST_SPLITS | Store uops that split cache line boundary | This event counts the number of retire stores that experienced cache line boundary splits |
| 03H | 08H | REHABQ.LD_SPLITS | Load uops that split cache line boundary | This event counts the number of retire loads that experienced cache line boundary splits |
| 03H | 10H | REHABQ.LOCK | Uops with lock semantics | This event counts the number of retired memory operations with lock semantics. These are either implicit locked instructions such as the XCHG instruction or instructions with an explicit LOCK prefix (F0H). |
| 03H | 20H | REHABQ.STA_FULL | Store address buffer full | This event counts the number of retired stores that are delayed because there is not a store address buffer available. |
| 03H | 40H | REHABQ.ANY_LD | Any reissued load uops | This event counts the number of load uops reissued from Rehabq |
| 03H | 80H | REHABQ.ANY_ST | Any reissued store uops | This event counts the number of store uops reissued from Rehabq |
| REAHBQ is an internal queue in the Silvermont microarchitecture that holds memory reference micro-ops which cannot complete for one reason or another. The micro-ops remain in the REHABQ until they can be re-issued and successfully completed.<br>Examples of bottlenecks that cause micro-ops to go into REHABQ include, but are not limited to: cache line splits, blocked store forward and data not ready. There are many other conditions that might cause a load or store to be sent to the REHABQ-- for instance, if an older store has an unknown address, all subsequent stores must be sent to the REHABQ until that older stores address becomes known | | | | |
| 04H | 01H | MEM_UOPS_RETIRED.L1_MISS_LOADS | Loads retired that missed L1 data cache | This event counts the number of load ops retired that miss in L1 Data cache. Note that prefetch misses will not be counted. |
| 04H | 02H | MEM_UOPS_RETIRED.L2_HIT_LOADS | Loads retired that hit L2 | This event counts the number of load micro-ops retired that hit L2. |
| 04H | 04H | MEM_UOPS_RETIRED.L2_MISS_LOADS | Loads retired that missed L2 | This event counts the number of load micro-ops retired that missed L2. |
| 04H | 08H | MEM_UOPS_RETIRED.DTLB_MISS_LOADS | Loads missed DTLB | This event counts the number of load ops retired that had DTLB miss. |
| 04H | 10H | MEM_UOPS_RETIRED.UTLB_MISS | Loads missed UTLB | This event counts the number of load ops retired that had UTLB miss. |
| 04H | 20H | MEM_UOPS_RETIRED.HITM | Cross core or cross module hitm | This event counts the number of load ops retired that got data from the other core or from the other module. |
| 04H | 40H | MEM_UOPS_RETIRED.ALL_LOADS | All Loads | This event counts the number of load ops retired |

**Table 19-20. Performance Events for Silvermont Microarchitecture**

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 04H | 80H | MEM_UOP_RETIRED.ALL_STORES | All Stores | This event counts the number of store ops retired |
| 05H | 01H | PAGE_WALKS.D_SIDE_CYCLES | Duration of D-side page-walks in core cycles | This event counts every cycle when a D-side (walks due to a load) page walk is in progress. Page walk duration divided by number of page walks is the average duration of page-walks.<br>Edge trigger bit must be cleared. Set Edge to count the number of page walks. |
| 05H | 02H | PAGE_WALKS.I_SIDE_CYCLES | Duration of I-side page-walks in core cycles | This event counts every cycle when a I-side (walks due to an instruction fetch) page walk is in progress. Page walk duration divided by number of page walks is the average duration of page-walks.<br>Edge trigger bit must be cleared. Set Edge to count the number of page walks. |
| 05H | 03H | PAGE_WALKS.WALKS | Total number of page-walks that are completed (I-side and D-side) | This event counts when a data (D) page walk or an instruction (I) page walk is completed or started. Since a page walk implies a TLB miss, the number of TLB misses can be counted by counting the number of pagewalks.<br>Edge trigger bit must be set. Clear Edge to count the number of cycles. |
| 2EH | 41H | LONGEST_LAT_CACHE.MISS | L2 cache request misses | This event counts the total number of L2 cache references and the number of L2 cache misses respectively.<br>L3 is not supported in Silvermont microarchitecture. |
| 2EH | 4FH | LONGEST_LAT_CACHE.REFERENCE | L2 cache requests from this core | This event counts requests originating from the core that references a cache line in the L2 cache.<br>L3 is not supported in Silvermont microarchitecture. |
| 30H | 00H | L2_REJECT_XQ.ALL | Counts the number of request from the L2 that were not accepted into the XQ | This event counts the number of demand and prefetch transactions that the L2 XQ rejects due to a full or near full condition which likely indicates back pressure from the IDI link. The XQ may reject transactions from the L2Q (non-cacheable requests), BBS (L2 misses) and WOB (L2 write-back victims) |
| When a memory reference misses the 1st level cache, the request goes to the L2 Queue (L2Q). If the request also misses the 2nd level cache, the request is sent to the XQ, where it waits for an opportunity to be issued to memory across the IDI link. Note that since the L2 is shared between a pair of processor cores, a single L2Q is shared between those two cores. Similarly, there is a single XQ for a pair of processors, situated between the L2Q and the IDI link.<br>The XQ will fill up when the response rate from the IDI link is smaller than the rate at which new requests arrive at the XQ. The event L2_reject_XQ indicates that a request is unable to move from the L2 Queue to the XQ because the XQ is full, and thus indicates that the memory system is oversubscribed | | | | |
| 31H | 00H | CORE_REJECT_L2Q.ALL | Counts the number of request that were not accepted into the L2Q because the L2Q is FULL. | This event counts the number of demand and L1 prefetcher requests rejected by the L2Q due to a full or nearly full condition which likely indicates back pressure from L2Q. It also counts requests that would have gone directly to the XQ, but are rejected due to a full or nearly full condition, indicating back pressure from the IDI link. The L2Q may also reject transactions from a core to insure fairness between cores, or to delay a core's dirty eviction when the address conflicts incoming external snoops. (Note that L2 prefetcher requests that are dropped are not counted by this event.). |

## Table 19-20. Performance Events for Silvermont Microarchitecture

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| The core_reject event indicates that a request from the core cannot be accepted at the L2Q. However, there are several additional reasons why a request might be rejected from the L2Q. Beyond rejecting a request because the L2Q is full, a request from one core can be rejected to maintain fairness to the other core. That is, one core is not permitted to monopolize the shared connection to the L2Q/cache/XQ/IDI links, and might have its requests rejected even when there is room available in the L2Q. In addition, if the request from the core is a dirty L1 cache eviction, the hardware must insure that this eviction does not conflict with any pending request in the L2Q. (pending requests can include an external snoop). In the event of a conflict, the dirty eviction request might be rejected even when there is room in the L2Q.<br>Thus, while the L2_reject_XQ event indicates that the request rate to memory from both cores exceeds the response rate of the memory, the Core_reject event is more subtle. It can indicate that the request rate to the L2Q exceeds the response rate from the XQ, or it can indicate the request rate to the L2Q exceeds the response rate from the L2, or it can indicate that one core is attempting to request more than its fair share of response from the L2Q. Or, it can be an indicator of conflict between dirty evictions and other pending requests.<br>In short, the L2_reject_XQ event indicates memory oversubscription. The Core_reject event can indicate either (1) memory oversubscription, (2) L2 oversubscription, (3) rejecting one cores requests to insure fairness to the other core, or (4) a conflict between dirty evictions and other pending requests. | | | | |
| 3CH | 00H | CPU_CLK_UNHALTED.CORE_P | Core cycles when core is not halted | This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. In mobile systems the core frequency may change from time to time. For this reason this event may have a changing ratio with regards to time. |
| N/A | 01H | CPU_CLK_UNHALTED.CORE | Instructions retired | This uses the fixed counter 1 to count the same condition as CPU_CLK_UNHALTED.CORE_P does. |
| 3CH | 01H | CPU_CLK_UNHALTED.REF_P | Reference cycles when core is not halted | This event counts the number of reference cycles that the core is not in a halt state. The core enters the halt state when it is running the HLT instruction.<br>In mobile systems the core frequency may change from time. This event is not affected by core frequency changes but counts as if the core is running at the maximum frequency all the time. |
| N/A | 02H | CPU_CLK_UNHALTED.REF_TSC | Instructions retired | This uses the fixed counter 2 to count the same condition as CPU_CLK_UNHALTED.REF_P does. |
| 80H | 01H | ICACHE.HIT | Instruction fetches from Icache | This event counts all instruction fetches from the instruction cache. |
| 80H | 02H | ICACHE.MISSES | Icache miss | This event counts all instruction fetches that miss the Instruction cache or produce memory requests. This includes uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding. |
| 80H | 03H | ICACHE.ACCESSES | Instruction fetches | This event counts all instruction fetches, including uncacheable fetches. |
| B6H | 04H | NIP_STALL.ICACHE_MISS | Counts the number of cycles the NIP stalls because of an icache miss. | Counts the number of cycles the NIP stalls because of an icache miss. This is a cumulative count of cycles the NIP stalled for all icache misses |
| B7H | 01H | OFFCORE_RESPONSE_0 | see Section 18.6.2 | Requires MSR_OFFCORE_RESP0 to specify request type and response. |
| B7H | 02H | OFFCORE_RESPONSE_1 | see Section 18.6.2 | Requires MSR_OFFCORE_RESP1 to specify request type and response. |

## Table 19-20. Performance Events for Silvermont Microarchitecture

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| C0H | 00H | INST_RETIRED.ANY_P | Instructions retired (PEBS supported with IA32_PMC0). | This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers. |
| N/A | 00H | INST_RETIRED.ANY | Instructions retired | This uses the fixed counter 0 to count the same condition as INST_RETIRED.ANY_P does. |
| C2H | 01H | UOPS_RETIRED.MS | MSROM micro-ops retired | This event counts the number of micro-ops retired that were supplied from MSROM. |
| C2H | 10H | UOPS_RETIRED.ALL | Micro-ops retired | This event counts the number of micro-ops retired. |
| The processor decodes complex macro instructions into a sequence of simpler micro-ops. Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. In some cases micro-op sequences are fused or whole instructions are fused into one micro-op. See other UOPS_RETIRED events for differentiating retired fused and non-fused micro-ops. | | | | |
| C3H | 01H | MACHINE_CLEARS.SMC | Self-Modifying Code detected | This event counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel® architecture processors. |
| C3H | 02H | MACHINE_CLEARS.MEMORY_ORDERING | Stalls due to Memory ordering | This event counts the number of times that pipeline was cleared due to memory ordering issues. |
| C3H | 04H | MACHINE_CLEARS.FP_ASSIST | Stalls due to FP assists | This event counts the number of times that pipeline stalled due to FP operations needing assists. |
| C3H | 08H | MACHINE_CLEARS.ALL | Stalls due to any causes | This event counts the number of times that pipeline stalled due to due to any causes (including SMC, MO, FP assist, etc). |
| There are many conditions that might cause a machine clear (including the receipt of an interrupt, or a trap or a fault). All those conditions (including but not limited to MO, SMC and FP) are captured in the ANY event. In addition, some conditions can be specifically counted (i.e. SMC, MO, FP). However, the sum of SMC, MO and FP machine clears will not necessarily equal the number of ANY.<br>FP Assist: Most of the time, the floating point execute unit can properly produce the correct output bits. On rare occasions, it needs a little help. When help is needed, a machine clear is asserted against the instruction. After this machine clear (as described above), the front end of the machine begins to deliver instructions that will figure out exactly what FP operation was asked for, and they will do the extra work to produce the correct FP result (for instance, if the result was a floating point denormal, sometimes the hardware asks the help to produce the correctly rounded IEEE compliant result).<br>SMC: (Self modifying code) The SMC happens when the machine fears that an instruction “in flight” is being changed. For instance, if you wrote a piece of code that wrote to the instruction stream ahead of where you were executing. In the Silvermont microarchitecture, the detection works in a 1K aligned region.<br>If you write to memory within 1K of where you are executing, the hardware may get concerned that an instruction is being modified and a machine clear might be signaled. Since the machine clear allows the store pipeline to drain, when front end restart occurs the correct instructions (after the write) will be executed. | | | | |
| MO: (Memory order) The MO machine clear happens when a snoop request occurs and the machine is uncertain if memory ordering will be preserved. For instance, suppose you have two loads, one to address X followed by another to address Y in the program order. Both loads have been issued; however, load to Y completes first and all the dependent ops on this load continue with the data loaded by this load. Load to X is still waiting for the data. Suppose that at the same time another processor writes to the same address Y and causes a snoop to address Y.<br>This presents a problem: the load to Y got the old value, but we have not yet finished loading X. So the other processor saw the loads in a different order by not consuming the latest value from the store to address Y. So we need to un-do everything from the load to address Y so that we will see the post-write data. Note we do not have to un-do load Y if there were no other pending reads-- the fact that the load to X is not yet finished causes this ordering problem. | | | | |
| C4H | 00H | BR_INST_RETIRED.ALL_BRANCHES | Retired branch instructions | This event counts the number of branch instructions retired. |

## Table 19-20. Performance Events for Silvermont Microarchitecture

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| C4H | 7EH | BR_INST_RETIRED.JCC | Retired branch instructions that were conditional jumps | This event counts the number of branch instructions retired that were conditional jumps. |
| C4H | BFH | BR_INST_RETIRED.FAR_BRANCH | Retired far branch instructions | This event counts the number of far branch instructions retired. |
| C4H | EBH | BR_INST_RETIRED.NON_RETURN_IND | Retired instructions of near indirect Jmp or call | This event counts the number of branch instructions retired that were near indirect call or near indirect jmp. |
| C4H | F7H | BR_INST_RETIRED.RETURN | Retired near return instructions | This event counts the number of near RET branch instructions retired |
| C4H | F9H | BR_INST_RETIRED.CALL | Retired near call instructions | This event counts the number of near CALL branch instructions retired |
| C4H | FBH | BR_INST_RETIRED.IND_CALL | Retired near indirect call instructions | This event counts the number of near indirect CALL branch instructions retired |
| C4H | FDH | BR_INST_RETIRED.REL_CALL | Retired near relative call instructions | This event counts the number of near relative CALL branch instructions retired |
| C4H | FEH | BR_INST_RETIRED.TAKEN_JCC | Retired conditional jumps that were predicted taken | This event counts the number of branch instructions retired that were conditional jumps and predicted taken. |
| C5H | 00H | BR_MISP_RETIRED.ALL_BRANCHES | Retired mispredicted branch instructions | This event counts the number of mispredicted branch instructions retired. |
| C5H | 7EH | BR_MISP_RETIRED.JCC | Retired mispredicted conditional jumps | This event counts the number of mispredicted branch instructions retired that were conditional jumps. |
| C5H | BFH | BR_MISP_RETIRED.FAR | Retired mispredicted far branch instructions | This event counts the number of mispredicted far branch instructions retired. |
| C5H | EBH | BR_MISP_RETIRED.NON_RETURN_IND | Retired mispredicted instructions of near indirect Jmp or call | This event counts the number of mispredicted branch instructions retired that were near indirect call or near indirect jmp. |
| C5H | F7H | BR_MISP_RETIRED.RETURN | Retired mispredicted near return instructions | This event counts the number of mispredicted near RET branch instructions retired |
| C5H | F9H | BR_MISP_RETIRED.CALL | Retired mispredicted near call instructions | This event counts the number of mispredicted near CALL branch instructions retired |
| C5H | FBH | BR_MISP_RETIRED.IND_CALL | Retired mispredicted near indirect call instructions | This event counts the number of mispredicted near indirect CALL branch instructions retired |
| C5H | FDH | BR_MISP_RETIRED.REL_CALL | Retired mispredicted near relative call instructions | This event counts the number of mispredicted near relative CALL branch instructions retired |
| C5H | FEH | BR_MISP_RETIRED.TAKEN_JCC | Retired mispredicted conditional jumps that were predicted taken | This event counts the number of mispredicted branch instructions retired that were conditional jumps and predicted taken. |
| CAH | 01H | NO_ALLOC_CYCLES.ROB_FULL | Counts the number of cycles when no uops are allocated and the ROB is full (less than 2 entries available) | Counts the number of cycles when no uops are allocated and the ROB is full (less than 2 entries available) |

## Table 19-20. Performance Events for Silvermont Microarchitecture

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| CAH | 20H | NO_ALLOC_CYCLES.RAT_STALL | Counts the number of cycles when no uops are allocated and a RATstall is asserted. | Counts the number of cycles when no uops are allocated and a RATstall is asserted. |
| CAH | 3FH | NO_ALLOC_CYCLES.ALL | Front end not delivering | This event counts the number of cycles when the front-end does not provide any instructions to be allocated for any reason |
| CAH | 50H | NO_ALLOC_CYCLES.NOT_DELIVERED | Front end not delivering backend not stalled | This event counts the number of cycles when the front-end does not provide any instructions to be allocated but the back end is not stalled |
| The front-end is responsible for fetching the instruction, decoding into micro-ops (uops) and putting them into a micro-op queue to be consumed by back end. The back-end then takes these micro-ops, allocates the required resources. When all resources are ready, micro-ops are executed. If the back-end is not ready to accept micro-ops from the front-end, then we do not want to count these as front-end bottlenecks. However, whenever we have bottlenecks in the back-end, we will have allocation unit stalls and eventually forcing the front-end to wait until the back-end is ready to receive more UOPS. This event counts the cycles only when back-end is requesting more micro-uops and front-end is not able to provide them. | | | | |
| CBH | 01H | RS_FULL_STALL.MEC | MEC RS full | This event counts the number of cycles the allocation pipe line stalled due to the RS for the MEC cluster is full |
| CBH | 1FH | RS_FULL_STALL.ALL | Any RS full | This event counts the number of cycles that the allocation pipe line stalled due to any one of the RS is full |
| The Silvermont microarchitecture has an allocation pipeline (AKA the RAT) that moves UOPS from the front end to the backend. At the end of the allocate pipe a UOP needs to be written into one of 6 reservation stations (the RS). Each RS holds UOPS that are to be sent to a specific execution (or memory) cluster. Each RS has a finite capacity, and it may accumulate UOPS when it is unable to send a UOP to its execution cluster. Typical reasons why an RS may fill include, but are not limited to, execution of long latency UOPS like divide, or inability to schedule UOPS due to dependencies, or too many outstanding memory references. When the RS becomes full, it is unable to accept more UOPS, and it will stall the allocation pipeline. The RS_FULL_STALL.ANY event will be asserted on any cycle when the allocation is stalled for any one of the RSs being full and not for other reasons. (i.e. the allocate pipeline might be stalled for some other reason, but if RS is not full, the RS_FULL_STALL.ANY will not count) The subevents allow discovery of exactly which RS (or RSs) that are full that prevent further allocation. | | | | |
| CDH | 01H | CYCLES_DIV_BUSY.ANY | Divider Busy | This event counts the number of cycles the divider is busy. |
| This event counts the cycles when the divide unit is unable to accept a new divide UOP because it is busy processing a previously dispatched UOP. The cycles will be counted irrespective of whether or not another divide UOP is waiting to enter the divide unit (from the RS). This event will count cycles while a divide is in progress even if the RS is empty. | | | | |
| E6H | 01H | BACLEARS.ALL | BACLEARS asserted for any branch | This event counts the number of baclears for any type of branch. |
| E6H | 08H | BACLEARS.RETURN | BACLEARS asserted for return branch | This event counts the number of baclears for return branches. |
| E6H | 10H | BACLEARS.COND | BACLEARS asserted for conditional branch | This event counts the number of baclears for conditional branches. |
| E7H | 01H | MS_DECODED.MS_ENTRY | MS Decode starts | This event counts the number of times the MSROM starts a flow of UOPS. |

## 19.11 PERFORMANCE MONITORING EVENTS FOR INTEL® ATOM™ PROCESSORS

Processors based on the Intel® Atom™ microarchitecture support the architectural performance-monitoring events listed in Table 19-1 and fixed-function performance events using fixed counter listed in Table 19-18. In addition, they also support the following non-architectural performance-monitoring events listed in Table 19-21.

**Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors**

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 02H | 81H | STORe_FORWARDS.GOOD | Good store forwards | This event counts the number of times store data was forwarded directly to a load. |
| 06H | 00H | SEGMENT_REG_LOADS.ANY | Number of segment register loads | This event counts the number of segment register load operations. Instructions that load new values into segment registers cause a penalty. This event indicates performance issues in 16-bit code. If this event occurs frequently, it may be useful to calculate the number of instructions retired per segment register load. If the resulting calculation is low (on average a small number of instructions are executed between segment register loads), then the code's segment register usage should be optimized.<br>As a result of branch misprediction, this event is speculative and may include segment register loads that do not actually occur. However, most segment register loads are internally serialized and such speculative effects are minimized. |
| 07H | 01H | PREFETCH.PREFETCHT0 | Streaming SIMD Extensions (SSE) PrefetchT0 instructions executed. | This event counts the number of times the SSE instruction prefetchT0 is executed. This instruction prefetches the data to the L1 data cache and L2 cache. |
| 07H | 06H | PREFETCH.SW_L2 | Streaming SIMD Extensions (SSE) PrefetchT1 and PrefetchT2 instructions executed | This event counts the number of times the SSE instructions prefetchT1 and prefetchT2 are executed. These instructions prefetch the data to the L2 cache. |
| 07H | 08H | PREFETCH.PREFETCHNTA | Streaming SIMD Extensions (SSE) Prefetch NTA instructions executed | This event counts the number of times the SSE instruction prefetchNTA is executed. This instruction prefetches the data to the L1 data cache. |
| 08H | 07H | DATA_TLB_MISSES.DTLB_MISS | Memory accesses that missed the DTLB | This event counts the number of Data Table Lookaside Buffer (DTLB) misses. The count includes misses detected as a result of speculative accesses. Typically a high count for this event indicates that the code accesses a large number of data pages. |
| 08H | 05H | DATA_TLB_MISSES.DTLB_MISS_LD | DTLB misses due to load operations | This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to load operations. This count includes misses detected as a result of speculative accesses. |
| 08H | 09H | DATA_TLB_MISSES.L0_DTLB_MISS_LD | L0_DTLB misses due to load operations | This event counts the number of L0_DTLB misses due to load operations. This count includes misses detected as a result of speculative accesses. |
| 08H | 06H | DATA_TLB_MISSES.DTLB_MISS_ST | DTLB misses due to store operations | This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to store operations. This count includes misses detected as a result of speculative accesses. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 0CH | 03H | PAGE_WALKS.WALKS | Number of page-walks executed | This event counts the number of page-walks executed due to either a DTLB or ITLB miss. The page walk duration, PAGE_WALKS.CYCLES, divided by number of page walks is the average duration of a page walk. This can hint to whether most of the page-walks are satisfied by the caches or cause an L2 cache miss.<br>Edge trigger bit must be set. |
| 0CH | 03H | PAGE_WALKS.CYCLES | Duration of page-walks in core cycles | This event counts the duration of page-walks in core cycles. The paging mode in use typically affects the duration of page walks. Page walk duration divided by number of page walks is the average duration of page-walks. This can hint at whether most of the page-walks are satisfied by the caches or cause an L2 cache miss.<br>Edge trigger bit must be cleared. |
| 10H | 01H | X87_COMP_OPS_EXE.ANY.S | Floating point computational micro-ops executed | This event counts the number of x87 floating point computational micro-ops executed. |
| 10H | 81H | X87_COMP_OPS_EXE.ANY.AR | Floating point computational micro-ops retired | This event counts the number of x87 floating point computational micro-ops retired. |
| 11H | 01H | FP_ASSIST | Floating point assists | This event counts the number of floating point operations executed that required micro-code assist intervention. These assists are required in the following cases:<br>X87 instructions:<br>1. NaN or denormal are loaded to a register or used as input from memory<br>2. Division by 0<br>3. Underflow output |
| 11H | 81H | FP_ASSIST.AR | Floating point assists | This event counts the number of floating point operations executed that required micro-code assist intervention. These assists are required in the following cases:<br>X87 instructions:<br>1. NaN or denormal are loaded to a register or used as input from memory<br>2. Division by 0<br>3. Underflow output |
| 12H | 01H | MUL.S | Multiply operations executed | This event counts the number of multiply operations executed. This includes integer as well as floating point multiply operations. |
| 12H | 81H | MUL.AR | Multiply operations retired | This event counts the number of multiply operations retired. This includes integer as well as floating point multiply operations. |
| 13H | 01H | DIV.S | Divide operations executed | This event counts the number of divide operations executed. This includes integer divides, floating point divides and square-root operations executed. |
| 13H | 81H | DIV.AR | Divide operations retired | This event counts the number of divide operations retired. This includes integer divides, floating point divides and square-root operations executed. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 14H | 01H | CYCLES_DIV_BUSY | Cycles the driver is busy | This event counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE. |
| 21H | See Table 18-2 | L2_ADS | Cycles L2 address bus is in use | This event counts the number of cycles the L2 address bus is being used for accesses to the L2 cache or bus queue.<br>This event can count occurrences for this core or both cores. |
| 22H | See Table 18-2 | L2_DBUS_BUSY | Cycles the L2 cache data bus is busy | This event counts core cycles during which the L2 cache data bus is busy transferring data from the L2 cache to the core. It counts for all L1 cache misses (data and instruction) that hit the L2 cache. The count will increment by two for a full cache-line request. |
| 24H | See Table 18-2 and Table 18-4 | L2_LINES_IN | L2 cache misses | This event counts the number of cache lines allocated in the L2 cache. Cache lines are allocated in the L2 cache as a result of requests from the L1 data and instruction caches and the L2 hardware prefetchers to cache lines that are missing in the L2 cache.<br>This event can count occurrences for this core or both cores. This event can also count demand requests and L2 hardware prefetch requests together or separately. |
| 25H | See Table 18-2 | L2_M_LINES_IN | L2 cache line modifications | This event counts whenever a modified cache line is written back from the L1 data cache to the L2 cache.<br>This event can count occurrences for this core or both cores. |
| 26H | See Table 18-2 and Table 18-4 | L2_LINES_OUT | L2 cache lines evicted | This event counts the number of L2 cache lines evicted.<br>This event can count occurrences for this core or both cores. This event can also count evictions due to demand requests and L2 hardware prefetch requests together or separately. |
| 27H | See Table 18-2 and Table 18-4 | L2_M_LINES_OUT | Modified lines evicted from the L2 cache | This event counts the number of L2 modified cache lines evicted. These lines are written back to memory unless they also exist in a shared-state in one of the L1 data caches.<br>This event can count occurrences for this core or both cores. This event can also count evictions due to demand requests and L2 hardware prefetch requests together or separately. |
| 28H | See Table 18-2 and Table 18-5 | L2_IFETCH | L2 cacheable instruction fetch requests | This event counts the number of instruction cache line requests from the ICache. It does not include fetch requests from uncacheable memory. It does not include ITLB miss accesses.<br>This event can count occurrences for this core or both cores. This event can also count accesses to cache lines at different MESI states. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 29H | See Table 18-2, Table 18-4 and Table 18-5 | L2_LD | L2 cache reads | This event counts L2 cache read requests coming from the L1 data cache and L2 prefetchers.<br>This event can count occurrences for this core or both cores. This event can count occurrences<br>- for this core or both cores.<br>- due to demand requests and L2 hardware prefetch requests together or separately.<br>- of accesses to cache lines at different MESI states. |
| 2AH | See Table 18-2 and Table 18-5 | L2_ST | L2 store requests | This event counts all store operations that miss the L1 data cache and request the data<br>from the L2 cache.<br>This event can count occurrences for this core or both cores. This event can also count accesses to cache lines at different MESI states. |
| 2BH | See Table 18-2 and Table 18-5 | L2_LOCK | L2 locked accesses | This event counts all locked accesses to cache lines that miss the L1 data cache.<br>This event can count occurrences for this core or both cores. This event can also count accesses to cache lines at different MESI states. |
| 2EH | See Table 18-2, Table 18-4 and Table 18-5 | L2_RQSTS | L2 cache requests | This event counts all completed L2 cache requests. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, instruction fetches, and all L2 hardware prefetch requests.<br>This event can count occurrences<br>- for this core or both cores.<br>- due to demand requests and L2 hardware prefetch requests together, or separately.<br>- of accesses to cache lines at different MESI states. |
| 2EH | 41H | L2_RQSTS.SELF.DEMAND.I_STATE | L2 cache demand requests from this core that missed the L2 | This event counts all completed L2 cache demand requests from this core that miss the L2 cache. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.<br>**This is an architectural performance event.** |
| 2EH | 4FH | L2_RQSTS.SELF.DEMAND.MESI | L2 cache demand requests from this core | This event counts all completed L2 cache demand requests from this core. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.<br>**This is an architectural performance event.** |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 30H | See Table 18-2, Table 18-4 and Table 18-5 | L2_REJECT_BUSQ | Rejected L2 cache requests | This event indicates that a pending L2 cache request that requires a bus transaction is delayed from moving to the bus queue. Some of the reasons for this event are:<br>- The bus queue is full.<br>- The bus queue already holds an entry for a cache line in the same set.<br>The number of events is greater or equal to the number of requests that were rejected.<br>- for this core or both cores.<br>- due to demand requests and L2 hardware prefetch requests together, or separately.<br>- of accesses to cache lines at different MESI states. |
| 32H | See Table 18-2 | L2_NO_REQ | Cycles no L2 cache requests are pending | This event counts the number of cycles that no L2 cache requests are pending. |
| 3AH | 00H | EIST_TRANS | Number of Enhanced Intel SpeedStep(R) Technology (EIST) transitions | This event counts the number of Enhanced Intel SpeedStep(R) Technology (EIST) transitions that include a frequency change, either with or without VID change. This event is incremented only while the counting core is in C0 state. In situations where an EIST transition was caused by hardware as a result of CxE state transitions, those EIST transitions will also be registered in this event.<br>Enhanced Intel Speedstep Technology transitions are commonly initiated by OS, but can be initiated by HW internally. For example: CxE states are C-states (C1,C2,C3...) which not only place the CPU into a sleep state by turning off the clock and other components, but also lower the voltage (which reduces the leakage power consumption). The same is true for thermal throttling transition which uses Enhanced Intel Speedstep Technology internally. |
| 3BH | C0H | THERMAL_TRIP | Number of thermal trips | This event counts the number of thermal trips. A thermal trip occurs whenever the processor temperature exceeds the thermal trip threshold temperature. Following a thermal trip, the processor automatically reduces frequency and voltage. The processor checks the temperature every millisecond, and returns to normal when the temperature falls below the thermal trip threshold temperature. |

**Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)**

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 3CH | 00H | CPU_CLK_UNHALTED.CORE_P | Core cycles when core is not halted | This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. This event is a component in many key event ratios.<br>In mobile systems the core frequency may change from time to time. For this reason this event may have a changing ratio with regards to time. In systems with a constant core frequency, this event can give you a measurement of the elapsed time while the core was not in halt state by dividing the event count by the core frequency.<br>-This is an architectural performance event.<br>- The event CPU_CLK_UNHALTED.CORE_P is counted by a programmable counter.<br>- The event CPU_CLK_UNHALTED.CORE is counted by a designated fixed counter, leaving the two programmable counters available for other events. |
| 3CH | 01H | CPU_CLK_UNHALTED.BUS | Bus cycles when core is not halted | This event counts the number of bus cycles while the core is not in the halt state. This event can give you a measurement of the elapsed time while the core was not in the halt state, by dividing the event count by the bus frequency. The core enters the halt state when it is running the HLT instruction.<br>The event also has a constant ratio with CPU_CLK_UNHALTED.REF event, which is the maximum bus to processor frequency ratio.<br>Non-halted bus cycles are a component in many key event ratios. |
| 3CH | 02H | CPU_CLK_UNHALTED.NO_OTHER | Bus cycles when core is active and the other is halted | This event counts the number of bus cycles during which the core remains non-halted, and the other core on the processor is halted.<br>This event can be used to determine the amount of parallelism exploited by an application or a system. Divide this event count by the bus frequency to determine the amount of time that only one core was in use. |
| 40H | 21H | L1D_CACHE.LD | L1 Cacheable Data Reads | This event counts the number of data reads from cacheable memory. |
| 40H | 22H | L1D_CACHE.ST | L1 Cacheable Data Writes | This event counts the number of data writes to cacheable memory. |
| 60H | See Table 18-2 and Table 18-3 | BUS_REQUEST_OUTSTANDING | Outstanding cacheable data read bus requests duration | This event counts the number of pending full cache line read transactions on the bus occurring in each cycle. A read transaction is pending from the cycle it is sent on the bus until the full cache line is received by the processor. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 61H | See Table 18-3 | BUS_BNR_DRV | Number of Bus Not Ready signals asserted | This event counts the number of Bus Not Ready (BNR) signals that the processor asserts on the bus to suspend additional bus requests by other bus agents. A bus agent asserts the BNR signal when the number of data and snoop transactions is close to the maximum that the bus can handle.<br>While this signal is asserted, new transactions cannot be submitted on the bus. As a result, transaction latency may have higher impact on program performance. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |
| 62H | See Table 18-3 | BUS_DRDY_CLOCKS | Bus cycles when data is sent on the bus | This event counts the number of bus cycles during which the DRDY (Data Ready) signal is asserted on the bus. The DRDY signal is asserted when data is sent on the bus.<br>This event counts the number of bus cycles during which this agent (the processor) writes data on the bus back to memory or to other bus agents. This includes all explicit and implicit data writebacks, as well as partial writes.<br>**NOTE:** This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |
| 63H | See Table 18-2 and Table 18-3 | BUS_LOCK_CLOCKS | Bus cycles when a LOCK signal is asserted. | This event counts the number of bus cycles, during which the LOCK signal is asserted on the bus. A LOCK signal is asserted when there is a locked memory access, due to:<br>- Uncacheable memory<br>- Locked operation that spans two cache lines<br>- Page-walk from an uncacheable page table.<br>Bus locks have a very high performance penalty and it is highly recommended to avoid such accesses. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |
| 64H | See Table 18-2 | BUS_DATA_RCV | Bus cycles while processor receives data | This event counts the number of cycles during which the processor is busy receiving data. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |
| 65H | See Table 18-2 and Table 18-3 | BUS_TRANS_BRD | Burst read bus transactions | This event counts the number of burst read transactions including:<br>- L1 data cache read misses (and L1 data cache hardware prefetches)<br>- L2 hardware prefetches by the DPL and L2 streamer<br>- IFU read misses of cacheable lines.<br>It does not include RFO transactions. |
| 66H | See Table 18-2 and Table 18-3 | BUS_TRANS_RFO | RFO bus transactions | This event counts the number of Read For Ownership (RFO) bus transactions, due to store operations that miss the L1 data cache and the L2 cache. This event also counts RFO bus transactions due to locked operations. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 67H | See Table 18-2 and Table 18-3 | BUS_TRANS_WB | Explicit writeback bus transactions | This event counts all explicit writeback bus transactions due to dirty line evictions. It does not count implicit writebacks due to invalidation by a snoop request. |
| 68H | See Table 18-2 and Table 18-3 | BUS_TRANS_IFETCH | Instruction-fetch bus transactions. | This event counts all instruction fetch full cache line bus transactions. |
| 69H | See Table 18-2 and Table 18-3 | BUS_TRANS_INVAL | Invalidate bus transactions | This event counts all invalidate transactions. Invalidate transactions are generated when:<br>- A store operation hits a shared line in the L2 cache.<br>- A full cache line write misses the L2 cache or hits a shared line in the L2 cache. |
| 6AH | See Table 18-2 and Table 18-3 | BUS_TRANS_PWR | Partial write bus transaction. | This event counts partial write bus transactions. |
| 6BH | See Table 18-2 and Table 18-3 | BUS_TRANS_P | Partial bus transactions | This event counts all (read and write) partial bus transactions. |
| 6CH | See Table 18-2 and Table 18-3 | BUS_TRANS_IO | IO bus transactions | This event counts the number of completed I/O bus transactions as a result of IN and OUT instructions. The count does not include memory mapped IO. |
| 6DH | See Table 18-2 and Table 18-3 | BUS_TRANS_DEF | Deferred bus transactions | This event counts the number of deferred transactions. |
| 6EH | See Table 18-2 and Table 18-3 | BUS_TRANS_BURST | Burst (full cache-line) bus transactions. | This event counts burst (full cache line) transactions including:<br>- Burst reads<br>- RFOs<br>- Explicit writebacks<br>- Write combine lines |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| 6FH | See Table 18-2 and Table 18-3 | BUS_TRANS_MEM | Memory bus transactions | This event counts all memory bus transactions including:<br>- burst transactions<br>- partial reads and writes<br>- invalidate transactions<br>The BUS_TRANS_MEM count is the sum of BUS_TRANS_BURST, BUS_TRANS_P and BUS_TRANS_INVAL. |
| 70H | See Table 18-2 and Table 18-3 | BUS_TRANS_ANY | All bus transactions | This event counts all bus transactions. This includes:<br>- Memory transactions<br>- IO transactions (non memory-mapped)<br>- Deferred transaction completion<br>- Other less frequent transactions, such as interrupts |
| 77H | See Table 18-2 and Table 18-5 | EXT_SNOOP | External snoops | This event counts the snoop responses to bus transactions. Responses can be counted separately by type and by bus agent. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |
| 7AH | See Table 18-3 | BUS_HIT_DRV | HIT signal asserted | This event counts the number of bus cycles during which the processor drives the HIT# pin to signal HIT snoop response. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |
| 7BH | See Table 18-3 | BUS_HITM_DRV | HITM signal asserted | This event counts the number of bus cycles during which the processor drives the HITM# pin to signal HITM snoop response. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |
| 7DH | See Table 18-2 | BUSQ_EMPTY | Bus queue is empty | This event counts the number of cycles during which the core did not have any pending transactions in the bus queue.<br>**NOTE:** This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |
| 7EH | See Table 18-2 and Table 18-3 | SNOOP_STALL_DRV | Bus stalled for snoops | This event counts the number of times that the bus snoop stall signal is asserted. During the snoop stall cycles no new bus transactions requiring a snoop response can be initiated on the bus. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled. |
| 7FH | See Table 18-2 | BUS_IO_WAIT | IO requests waiting in the bus queue | This event counts the number of core cycles during which IO requests wait in the bus queue. This event counts IO requests from the core. |
| 80H | 03H | ICACHE.ACCESSES | Instruction fetches | This event counts all instruction fetches, including uncacheable fetches. |
| 80H | 02H | ICACHE.MISSES | Icache miss | This event counts all instruction fetches that miss the Instruction cache or produce memory requests. This includes uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding. |
| 82H | 04H | ITLB.FLUSH | ITLB flushes | This event counts the number of ITLB flushes. |
| 82H | 02H | ITLB.MISSES | ITLB misses | This event counts the number of instruction fetches that miss the ITLB. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| AAH | 02H | MACRO_INSTS.CISC_DECODED | CISC macro instructions decoded | This event counts the number of complex instructions decoded, but not necessarily executed or retired. Only one complex instruction can be decoded at a time. |
| AAH | 03H | MACRO_INSTS.ALL_DECODED | All Instructions decoded | This event counts the number of instructions decoded. |
| B0H | 00H | SIMD_UOPS_EXEC.S | SIMD micro-ops executed (excluding stores) | This event counts all the SIMD micro-ops executed. This event does not count MOVQ and MOVD stores from register to memory. |
| B0H | 80H | SIMD_UOPS_EXEC.AR | SIMD micro-ops retired (excluding stores) | This event counts the number of SIMD saturated arithmetic micro-ops executed. |
| B1H | 00H | SIMD_SAT_UOP_EXEC.S | SIMD saturated arithmetic micro-ops executed | This event counts the number of SIMD saturated arithmetic micro-ops executed. |
| B1H | 80H | SIMD_SAT_UOP_EXEC.AR | SIMD saturated arithmetic micro-ops retired | This event counts the number of SIMD saturated arithmetic micro-ops retired. |
| B3H | 01H | SIMD_UOP_TYPE_EXEC.MUL.S | SIMD packed multiply micro-ops executed | This event counts the number of SIMD packed multiply micro-ops executed. |
| B3H | 81H | SIMD_UOP_TYPE_EXEC.MUL.AR | SIMD packed multiply micro-ops retired | This event counts the number of SIMD packed multiply micro-ops retired. |
| B3H | 02H | SIMD_UOP_TYPE_EXEC.SHIFT.S | SIMD packed shift micro-ops executed | This event counts the number of SIMD packed shift micro-ops executed. |
| B3H | 82H | SIMD_UOP_TYPE_EXEC.SHIFT.AR | SIMD packed shift micro-ops retired | This event counts the number of SIMD packed shift micro-ops retired. |
| B3H | 04H | SIMD_UOP_TYPE_EXEC.PACK.S | SIMD pack micro-ops executed | This event counts the number of SIMD pack micro-ops executed. |
| B3H | 84H | SIMD_UOP_TYPE_EXEC.PACK.AR | SIMD pack micro-ops retired | This event counts the number of SIMD pack micro-ops retired. |
| B3H | 08H | SIMD_UOP_TYPE_EXEC.UNPACK.S | SIMD unpack micro-ops executed | This event counts the number of SIMD unpack micro-ops executed. |
| B3H | 88H | SIMD_UOP_TYPE_EXEC.UNPACK.AR | SIMD unpack micro-ops retired | This event counts the number of SIMD unpack micro-ops retired. |
| B3H | 10H | SIMD_UOP_TYPE_EXEC.LOGICAL.S | SIMD packed logical micro-ops executed | This event counts the number of SIMD packed logical micro-ops executed. |
| B3H | 90H | SIMD_UOP_TYPE_EXEC.LOGICAL.AR | SIMD packed logical micro-ops retired | This event counts the number of SIMD packed logical micro-ops retired. |
| B3H | 20H | SIMD_UOP_TYPE_EXEC.ARITHMETIC.S | SIMD packed arithmetic micro-ops executed | This event counts the number of SIMD packed arithmetic micro-ops executed. |
| B3H | A0H | SIMD_UOP_TYPE_EXEC.ARITHMETIC.AR | SIMD packed arithmetic micro-ops retired | This event counts the number of SIMD packed arithmetic micro-ops retired. |
| C0H | 00H | INST_RETIRED.ANY_P | Instructions retired (precise event). | This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| N/A | 00H | INST_RETIRED.ANY | Instructions retired | This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers. |
| C2H | 10H | UOPS_RETIRED.ANY | Micro-ops retired | This event counts the number of micro-ops retired. The processor decodes complex macro instructions into a sequence of simpler micro-ops. Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. In some cases micro-op sequences are fused or whole instructions are fused into one micro-op. See other UOPS_RETIRED events for differentiating retired fused and non-fused micro-ops. |
| C3H | 01H | MACHINE_CLEARS.SMC | Self-Modifying Code detected | This event counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel® architecture processors. |
| C4H | 00H | BR_INST_RETIRED.ANY | Retired branch instructions | This event counts the number of branch instructions retired. **This is an architectural performance event.** |
| C4H | 01H | BR_INST_RETIRED.PRED_NOT_TAKEN | Retired branch instructions that were predicted not-taken | This event counts the number of branch instructions retired that were correctly predicted to be not-taken. |
| C4H | 02H | BR_INST_RETIRED.MISPRED_NOT_TAKEN | Retired branch instructions that were mispredicted not-taken | This event counts the number of branch instructions retired that were mispredicted and not-taken. |
| C4H | 04H | BR_INST_RETIRED.PRED_TAKEN | Retired branch instructions that were predicted taken | This event counts the number of branch instructions retired that were correctly predicted to be taken. |
| C4H | 08H | BR_INST_RETIRED.MISPRED_TAKEN | Retired branch instructions that were mispredicted taken | This event counts the number of branch instructions retired that were mispredicted and taken. |
| C4H | 0AH | BR_INST_RETIRED.MISPRED | Retired mispredicted branch instructions (precise event) | This event counts the number of retired branch instructions that were mispredicted by the processor. A branch misprediction occurs when the processor predicts that the branch would be taken, but it is not, or vice-versa. Mispredicted branches degrade the performance because the processor starts executing instructions along a wrong path it predicts. When the misprediction is discovered, all the instructions executed in the wrong path must be discarded, and the processor must start again on the correct path.<br>Using the Profile-Guided Optimization (PGO) features of the Intel® C++ compiler may help reduce branch mispredictions. See the compiler documentation for more information on this feature. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| | | | | To determine the branch misprediction ratio, divide the BR_INST_RETIRED.MISPRED event count by the number of BR_INST_RETIRED.ANY event count. To determine the number of mispredicted branches per instruction, divide the number of mispredicted branches by the INST_RETIRED.ANY event count. To measure the impact of the branch mispredictions use the event RESOURCE_STALLS.BR_MISS_CLEAR.<br>**Tips:**<br>- See the optimization guide for tips on reducing branch mispredictions.<br>- PGO's purpose is to have straight line code for the most frequent execution paths, reducing branches taken and increasing the "basic block" size, possibly also reducing the code footprint or working-set. |
| C4H | 0CH | BR_INST_RETIRED.TAKEN | Retired taken branch instructions | This event counts the number of branches retired that were taken. |
| C4H | 0FH | BR_INST_RETIRED.ANY1 | Retired branch instructions | This event counts the number of branch instructions retired that were mispredicted. This event is a duplicate of BR_INST_RETIRED.MISPRED. |
| C5H | 00H | BR_INST_RETIRED.MISPRED | Retired mispredicted branch instructions (precise event). | This event counts the number of retired branch instructions that were mispredicted by the processor. A branch misprediction occurs when the processor predicts that the branch would be taken, but it is not, or vice-versa. Mispredicted branches degrade the performance because the processor starts executing instructions along a wrong path it predicts. When the misprediction is discovered, all the instructions executed in the wrong path must be discarded, and the processor must start again on the correct path.<br>Using the Profile-Guided Optimization (PGO) features of the Intel® C++ compiler may help reduce branch mispredictions. See the compiler documentation for more information on this feature.<br>To determine the branch misprediction ratio, divide the BR_INST_RETIRED.MISPRED event count by the number of BR_INST_RETIRED.ANY event count. To determine the number of mispredicted branches per instruction, divide the number of mispredicted branches by the INST_RETIRED.ANY event count. To measure the impact of the branch mispredictions use the event RESOURCE_STALLS.BR_MISS_CLEAR.<br>**Tips:**<br>- See the optimization guide for tips on reducing branch mispredictions.<br>- PGO's purpose is to have straight line code for the most frequent execution paths, reducing branches taken and increasing the "basic block" size, possibly also reducing the code footprint or working-set. |
| C6H | 01H | CYCLES_INT_MASKED.CYCLES_INT_MASKED | Cycles during which interrupts are disabled | This event counts the number of cycles during which interrupts are disabled. |
| C6H | 02H | CYCLES_INT_MASKED.CYCLES_INT_PENDING_AND_MASKED | Cycles during which interrupts are pending and disabled | This event counts the number of cycles during which there are pending interrupts but interrupts are disabled. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| C7H | 01H | SIMD_INST_RETIRED.PACKED_SINGLE | Retired Streaming SIMD Extensions (SSE) packed-single instructions | This event counts the number of SSE packed-single instructions retired. |
| C7H | 02H | SIMD_INST_RETIRED.SCALAR_SINGLE | Retired Streaming SIMD Extensions (SSE) scalar-single instructions | This event counts the number of SSE scalar-single instructions retired. |
| C7H | 04H | SIMD_INST_RETIRED.PACKED_DOUBLE | Retired Streaming SIMD Extensions 2 (SSE2) packed-double instructions | This event counts the number of SSE2 packed-double instructions retired. |
| C7H | 08H | SIMD_INST_RETIRED.SCALAR_DOUBLE | Retired Streaming SIMD Extensions 2 (SSE2) scalar-double instructions. | This event counts the number of SSE2 scalar-double instructions retired. |
| C7H | 10H | SIMD_INST_RETIRED.VECTOR | Retired Streaming SIMD Extensions 2 (SSE2) vector instructions. | This event counts the number of SSE2 vector instructions retired. |
| C7H | 1FH | SIMD_INST_RETIRED.ANY | Retired Streaming SIMD instructions | This event counts the overall number of SIMD instructions retired. To count each type of SIMD instruction separately, use the following events:<br>SIMD_INST_RETIRED.PACKED_SINGLE, SIMD_INST_RETIRED.SCALAR_SINGLE, SIMD_INST_RETIRED.PACKED_DOUBLE, SIMD_INST_RETIRED.SCALAR_DOUBLE, and SIMD_INST_RETIRED.VECTOR. |
| C8H | 00H | HW_INT_RCV | Hardware interrupts received | This event counts the number of hardware interrupts received by the processor. This event will count twice for dual-pipe micro-ops. |
| CAH | 01H | SIMD_COMP_INST_RETIRED.PACKED_SINGLE | Retired computational Streaming SIMD Extensions (SSE) packed-single instructions. | This event counts the number of computational SSE packed-single instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |
| CAH | 02H | SIMD_COMP_INST_RETIRED.SCALAR_SINGLE | Retired computational Streaming SIMD Extensions (SSE) scalar-single instructions. | This event counts the number of computational SSE scalar-single instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |
| CAH | 04H | SIMD_COMP_INST_RETIRED.PACKED_DOUBLE | Retired computational Streaming SIMD Extensions 2 (SSE2) packed-double instructions. | This event counts the number of computational SSE2 packed-double instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |

Table 19-21. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

| Event Num. | Umask Value | Event Name | Definition | Description and Comment |
|---|---|---|---|---|
| CAH | 08H | SIMD_COMP_INST_RETIRED.SCALAR_DOUBLE | Retired computational Streaming SIMD Extensions 2 (SSE2) scalar-double instructions | This event counts the number of computational SSE2 scalar-double instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event. |
| CBH | 01H | MEM_LOAD_RETIRED.L2_HIT | Retired loads that hit the L2 cache (precise event) | This event counts the number of retired load operations that missed the L1 data cache and hit the L2 cache. |
| CBH | 02H | MEM_LOAD_RETIRED.L2_MISS | Retired loads that miss the L2 cache (precise event) | This event counts the number of retired load operations that missed the L2 cache. |
| CBH | 04H | MEM_LOAD_RETIRED.DTLB_MISS | Retired loads that miss the DTLB (precise event) | This event counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault. |
| CDH | 00H | SIMD_ASSIST | SIMD assists invoked | This event counts the number of SIMD assists invoked. SIMD assists are invoked when an EMMS instruction is executed after MMX™ technology code has changed the MMX state in the floating point stack. For example, these assists are required in the following cases:<br>Streaming SIMD Extensions (SSE) instructions:<br>1. Denormal input when the DAZ (Denormals Are Zeros) flag is off<br>2. Underflow result when the FTZ (Flush To Zero) flag is off |
| CEH | 00H | SIMD_INSTR_RETIRED | SIMD Instructions retired | This event counts the number of SIMD instructions that retired. |
| CFH | 00H | SIMD_SAT_INSTR_RETIRED | Saturated arithmetic instructions retired | This event counts the number of saturated arithmetic SIMD instructions that retired. |
| E0H | 01H | BR_INST_DECODED | Branch instructions decoded | This event counts the number of branch instructions decoded. |
| E4H | 01H | BOGUS_BR | Bogus branches | This event counts the number of byte sequences that were mistakenly detected as taken branch instructions. This results in a BACLEAR event and the BTB is flushed. This occurs mainly after task switches. |
| E6H | 01H | BACLEARS.ANY | BACLEARS asserted | This event counts the number of times the front end is redirected for a branch prediction, mainly when an early branch prediction is corrected by other branch handling mechanisms in the front-end. This can occur if the code has many branches such that they cannot be consumed by the branch predictor. Each Baclear asserted costs approximately 7 cycles. The effect on total execution time depends on the surrounding code. |

## 19.12 PERFORMANCE MONITORING EVENTS FOR INTEL® CORE™ SOLO AND INTEL® CORE™ DUO PROCESSORS

Table 19-22 lists non-architectural performance events for Intel® Core™ Duo processors. If a non-architectural event requires qualification in core specificity, it is indicated in the comment column. Table 19-22 also applies to Intel® Core™ Solo processors; bits in the unit mask corresponding to core-specificity are reserved and should be 00B.

**Table 19-22. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors**

| Event Num. | Event Mask Mnemonic | Umask Value | Description | Comment |
|---|---|---|---|---|
| 03H | LD_Blocks | 00H | Load operations delayed due to store buffer blocks.<br>The preceding store may be blocked due to unknown address, unknown data, or conflict due to partial overlap between the load and store. | |
| 04H | SD_Drains | 00H | Cycles while draining store buffers. | |
| 05H | Misalign_Mem_Ref | 00H | Misaligned data memory references (MOB splits of loads and stores). | |
| 06H | Seg_Reg_Loads | 00H | Segment register loads. | |
| 07H | SSE_PrefNta_Ret | 00H | SSE software prefetch instruction PREFETCHNTA retired. | |
| 07H | SSE_PrefT1_Ret | 01H | SSE software prefetch instruction PREFETCHT1 retired. | |
| 07H | SSE_PrefT2_Ret | 02H | SSE software prefetch instruction PREFETCHT2 retired. | |
| 07H | SSE_NTStores_Ret | 03H | SSE streaming store instruction retired. | |
| 10H | FP_Comps_Op_Exe | 00H | FP computational Instruction executed. FADD, FSUB, FCOM, FMULs, MUL, IMUL, FDIVs, DIV, IDIV, FPREMs, FSQRT are included; but exclude FADD or FMUL used in the middle of a transcendental instruction. | |
| 11H | FP_Assist | 00H | FP exceptions experienced microcode assists. | IA32_PMC1 only. |
| 12H | Mul | 00H | Multiply operations (a speculative count, including FP and integer multiplies). | IA32_PMC1 only. |
| 13H | Div | 00H | Divide operations (a speculative count, including FP and integer divisions). | IA32_PMC1 only. |
| 14H | Cycles_Div_Busy | 00H | Cycles the divider is busy. | IA32_PMC0 only. |
| 21H | L2_ADS | 00H | L2 Address strobes. | Requires core-specificity |
| 22H | Dbus_Busy | 00H | Core cycle during which data bus was busy (increments by 4). | Requires core-specificity |
| 23H | Dbus_Busy_Rd | 00H | Cycles data bus is busy transferring data to a core (increments by 4). | Requires core-specificity |
| 24H | L2_Lines_In | 00H | L2 cache lines allocated. | Requires core-specificity and HW prefetch qualification |
| 25H | L2_M_Lines_In | 00H | L2 Modified-state cache lines allocated. | Requires core-specificity |
| 26H | L2_Lines_Out | 00H | L2 cache lines evicted. | Requires core-specificity and HW prefetch qualification |
| 27H | L2_M_Lines_Out | 00H | L2 Modified-state cache lines evicted. | |

**Table 19-22. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic | Umask Value | Description | Comment |
|---|---|---|---|---|
| 28H | L2_IFetch | Requires MESI qualification | L2 instruction fetches from instruction fetch unit (includes speculative fetches). | Requires core-specificity |
| 29H | L2_LD | Requires MESI qualification | L2 cache reads. | Requires core-specificity |
| 2AH | L2_ST | Requires MESI qualification | L2 cache writes (includes speculation). | Requires core-specificity |
| 2EH | L2_Rqsts | Requires MESI qualification | L2 cache reference requests. | Requires core-specificity, HW prefetch qualification |
| 30H | L2_Reject_Cycles | Requires MESI qualification | Cycles L2 is busy and rejecting new requests. | |
| 32H | L2_No_Request_ Cycles | Requires MESI qualification | Cycles there is no request to access L2. | |
| 3AH | EST_Trans_All | 00H | Any Intel Enhanced SpeedStep(R) Technology transitions. | |
| 3AH | EST_Trans_All | 10H | Intel Enhanced SpeedStep Technology frequency transitions. | |
| 3BH | Thermal_Trip | C0H | Duration in a thermal trip based on the current core clock. | Use edge trigger to count occurrence |
| 3CH | NonHlt_Ref_Cycles | 01H | Non-halted bus cycles. | |
| 3CH | Serial_Execution_ Cycles | 02H | Non-halted bus cycles of this core executing code while the other core is halted. | |
| 40H | DCache_Cache_LD | Requires MESI qualification | L1 cacheable data read operations. | |
| 41H | DCache_Cache_ST | Requires MESI qualification | L1 cacheable data write operations. | |
| 42H | DCache_Cache_ Lock | Requires MESI qualification | L1 cacheable lock read operations to invalid state. | |
| 43H | Data_Mem_Ref | 01H | L1 data read and writes of cacheable and non-cacheable types. | |
| 44H | Data_Mem_Cache_ Ref | 02H | L1 data cacheable read and write operations. | |
| 45H | DCache_Repl | 0FH | L1 data cache line replacements. | |
| 46H | DCache_M_Repl | 00H | L1 data M-state cache line allocated. | |
| 47H | DCache_M_Evict | 00H | L1 data M-state cache line evicted. | |
| 48H | DCache_Pend_Miss | 00H | Weighted cycles of L1 miss outstanding. | Use Cmask =1 to count duration. |
| 49H | Dtlb_Miss | 00H | Data references that missed TLB. | |
| 4BH | SSE_PrefNta_Miss | 00H | PREFETCHNTA missed all caches. | |
| 4BH | SSE_PrefT1_Miss | 01H | PREFETCHT1 missed all caches. | |
| 4BH | SSE_PrefT2_Miss | 02H | PREFETCHT2 missed all caches. | |
| 4BH | SSE_NTStores_ Miss | 03H | SSE streaming store instruction missed all caches. | |
| 4FH | L1_Pref_Req | 00H | L1 prefetch requests due to DCU cache misses. | May overcount if request re-submitted |

**Table 19-22. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic | Umask Value | Description | Comment |
|---|---|---|---|---|
| 60H | Bus_Req_ Outstanding | 00; Requires core-specificity, and agent specificity | Weighted cycles of cacheable bus data read requests. This event counts full-line read request from DCU or HW prefetcher, but not RFO, write, instruction fetches, or others. | Use Cmask =1 to count duration.<br>Use Umask bit 12 to include HWP or exclude HWP separately. |
| 61H | Bus_BNR_Clocks | 00H | External bus cycles while BNR asserted. | |
| 62H | Bus_DRDY_Clocks | 00H | External bus cycles while DRDY asserted. | Requires agent specificity |
| 63H | Bus_Locks_Clocks | 00H | External bus cycles while bus lock signal asserted. | Requires core specificity |
| 64H | Bus_Data_Rcv | 40H | Number of data chunks received by this processor. | |
| 65H | Bus_Trans_Brd | See comment. | Burst read bus transactions (data or code). | Requires core specificity |
| 66H | Bus_Trans_RFO | See comment. | Completed read for ownership (RFO) transactions. | Requires agent specificity<br>Requires core specificity<br>Each transaction counts its address strobe<br>Retried transaction may be counted more than once |
| 68H | Bus_Trans_Ifetch | See comment. | Completed instruction fetch transactions. | |
| 69H | Bus_Trans_Inval | See comment. | Completed invalidate transactions. | |
| 6AH | Bus_Trans_Pwr | See comment. | Completed partial write transactions. | |
| 6BH | Bus_Trans_P | See comment. | Completed partial transactions (include partial read + partial write + line write). | |
| 6CH | Bus_Trans_IO | See comment. | Completed I/O transactions (read and write). | |
| 6DH | Bus_Trans_Def | 20H | Completed defer transactions. | Requires core specificity<br>Retried transaction may be counted more than once |
| 67H | Bus_Trans_WB | C0H | Completed writeback transactions from DCU (does not include L2 writebacks). | Requires agent specificity<br>Each transaction counts its address strobe<br>Retried transaction may be counted more than once |
| 6EH | Bus_Trans_Burst | C0H | Completed burst transactions (full line transactions include reads, write, RFO, and writebacks). | |
| 6FH | Bus_Trans_Mem | C0H | Completed memory transactions. This includes Bus_Trans_Burst + Bus_Trans_P+Bus_Trans_Inval. | |
| 70H | Bus_Trans_Any | C0H | Any completed bus transactions. | |
| 77H | Bus_Snoops | 00H | Counts any snoop on the bus. | Requires MESI qualification<br>Requires agent specificity |
| 78H | DCU_Snoop_To_ Share | 01H | DCU snoops to share-state L1 cache line due to L1 misses. | Requires core specificity |
| 7DH | Bus_Not_In_Use | 00H | Number of cycles there is no transaction from the core. | Requires core specificity |
| 7EH | Bus_Snoop_Stall | 00H | Number of bus cycles while bus snoop is stalled. | |
| 80H | ICache_Reads | 00H | Number of instruction fetches from ICache, streaming buffers (both cacheable and uncacheable fetches). | |
| 81H | ICache_Misses | 00H | Number of instruction fetch misses from ICache, streaming buffers. | |
| 85H | ITLB_Misses | 00H | Number of iITLB misses. | |

**Table 19-22. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic | Umask Value | Description | Comment |
|---|---|---|---|---|
| 86H | IFU_Mem_Stall | 00H | Cycles IFU is stalled while waiting for data from memory. | |
| 87H | ILD_Stall | 00H | Number of instruction length decoder stalls (Counts number of LCP stalls). | |
| 88H | Br_Inst_Exec | 00H | Branch instruction executed (includes speculation). | |
| 89H | Br_Missp_Exec | 00H | Branch instructions executed and mispredicted at execution (includes branches that do not have prediction or mispredicted). | |
| 8AH | Br_BAC_Missp_ Exec | 00H | Branch instructions executed that were mispredicted at front end. | |
| 8BH | Br_Cnd_Exec | 00H | Conditional branch instructions executed. | |
| 8CH | Br_Cnd_Missp_ Exec | 00H | Conditional branch instructions executed that were mispredicted. | |
| 8DH | Br_Ind_Exec | 00H | Indirect branch instructions executed. | |
| 8EH | Br_Ind_Missp_Exec | 00H | Indirect branch instructions executed that were mispredicted. | |
| 8FH | Br_Ret_Exec | 00H | Return branch instructions executed. | |
| 90H | Br_Ret_Missp_Exec | 00H | Return branch instructions executed that were mispredicted. | |
| 91H | Br_Ret_BAC_Missp_ Exec | 00H | Return branch instructions executed that were mispredicted at the front end. | |
| 92H | Br_Call_Exec | 00H | Return call instructions executed. | |
| 93H | Br_Call_Missp_Exec | 00H | Return call instructions executed that were mispredicted. | |
| 94H | Br_Ind_Call_Exec | 00H | Indirect call branch instructions executed. | |
| A2H | Resource_Stall | 00H | Cycles while there is a resource related stall (renaming, buffer entries) as seen by allocator. | |
| B0H | MMX_Instr_Exec | 00H | Number of MMX instructions executed (does not include MOVQ and MOVD stores). | |
| B1H | SIMD_Int_Sat_Exec | 00H | Number of SIMD Integer saturating instructions executed. | |
| B3H | SIMD_Int_Pmul_ Exec | 01H | Number of SIMD Integer packed multiply instructions executed. | |
| B3H | SIMD_Int_Psft_Exec | 02H | Number of SIMD Integer packed shift instructions executed. | |
| B3H | SIMD_Int_Pck_Exec | 04H | Number of SIMD Integer pack operations instruction executed. | |
| B3H | SIMD_Int_Upck_ Exec | 08H | Number of SIMD Integer unpack instructions executed. | |
| B3H | SIMD_Int_Plog_ Exec | 10H | Number of SIMD Integer packed logical instructions executed. | |
| B3H | SIMD_Int_Pari_Exec | 20H | Number of SIMD Integer packed arithmetic instructions executed. | |
| C0H | Instr_Ret | 00H | Number of instruction retired (Macro fused instruction count as 2). | |

Table 19-22. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)

| Event Num. | Event Mask Mnemonic | Umask Value | Description | Comment |
|---|---|---|---|---|
| C1H | FP_Comp_Instr_Ret | 00H | Number of FP compute instructions retired (X87 instruction or instruction that contain X87 operations). | Use IA32_PMC0 only. |
| C2H | Uops_Ret | 00H | Number of micro-ops retired (include fused uops). | |
| C3H | SMC_Detected | 00H | Number of times self-modifying code condition detected. | |
| C4H | Br_Instr_Ret | 00H | Number of branch instructions retired. | |
| C5H | Br_MisPred_Ret | 00H | Number of mispredicted branch instructions retired. | |
| C6H | Cycles_Int_Masked | 00H | Cycles while interrupt is disabled. | |
| C7H | Cycles_Int_Pedning_ Masked | 00H | Cycles while interrupt is disabled and interrupts are pending. | |
| C8H | HW_Int_Rx | 00H | Number of hardware interrupts received. | |
| C9H | Br_Taken_Ret | 00H | Number of taken branch instruction retired. | |
| CAH | Br_MisPred_Taken_ Ret | 00H | Number of taken and mispredicted branch instructions retired. | |
| CCH | MMX_FP_Trans | 00H | Number of transitions from MMX to X87. | |
| CCH | FP_MMX_Trans | 01H | Number of transitions from X87 to MMX. | |
| CDH | MMX_Assist | 00H | Number of EMMS executed. | |
| CEH | MMX_Instr_Ret | 00H | Number of MMX instruction retired. | |
| D0H | Instr_Decoded | 00H | Number of instruction decoded. | |
| D7H | ESP_Uops | 00H | Number of ESP folding instruction decoded. | |
| D8H | SIMD_FP_SP_Ret | 00H | Number of SSE/SSE2 single precision instructions retired (packed and scalar). | |
| D8H | SIMD_FP_SP_S_ Ret | 01H | Number of SSE/SSE2 scalar single precision instructions retired. | |
| D8H | SIMD_FP_DP_P_ Ret | 02H | Number of SSE/SSE2 packed double precision instructions retired. | |
| D8H | SIMD_FP_DP_S_ Ret | 03H | Number of SSE/SSE2 scalar double precision instructions retired. | |
| D8H | SIMD_Int_128_Ret | 04H | Number of SSE2 128 bit integer instructions retired. | |
| D9H | SIMD_FP_SP_P_ Comp_Ret | 00H | Number of SSE/SSE2 packed single precision compute instructions retired (does not include AND, OR, XOR). | |
| D9H | SIMD_FP_SP_S_ Comp_Ret | 01H | Number of SSE/SSE2 scalar single precision compute instructions retired (does not include AND, OR, XOR). | |
| D9H | SIMD_FP_DP_P_ Comp_Ret | 02H | Number of SSE/SSE2 packed double precision compute instructions retired (does not include AND, OR, XOR). | |
| D9H | SIMD_FP_DP_S_ Comp_Ret | 03H | Number of SSE/SSE2 scalar double precision compute instructions retired (does not include AND, OR, XOR). | |
| DAH | Fused_Uops_Ret | 00H | All fused uops retired. | |

**Table 19-22. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)**

| Event Num. | Event Mask Mnemonic | Umask Value | Description | Comment |
|---|---|---|---|---|
| DAH | Fused_Ld_Uops_ Ret | 01H | Fused load uops retired. | |
| DAH | Fused_St_Uops_Ret | 02H | Fused store uops retired. | |
| DBH | Unfusion | 00H | Number of unfusion events in the ROB (due to exception). | |
| E0H | Br_Instr_Decoded | 00H | Branch instructions decoded. | |
| E2H | BTB_Misses | 00H | Number of branches the BTB did not produce a prediction. | |
| E4H | Br_Bogus | 00H | Number of bogus branches. | |
| E6H | BAClears | 00H | Number of BAClears asserted. | |
| F0H | Pref_Rqsts_Up | 00H | Number of hardware prefetch requests issued in forward streams. | |
| F8H | Pref_Rqsts_Dn | 00H | Number of hardware prefetch requests issued in backward streams. | |

## 19.13 PENTIUM® 4 AND INTEL® XEON® PROCESSOR PERFORMANCE-MONITORING EVENTS

Tables 19-23, 19-24 and  list performance-monitoring events that can be counted or sampled on processors based on Intel NetBurst® microarchitecture. Table 19-23 lists the non-retirement events, and Table 19-24 lists the at-retirement events. Tables 19-26, 19-27, and 19-28 describes three sets of parameters that are available for three of the at-retirement counting events defined in Table 19-24. Table 19-29 shows which of the non-retirement and at retirement events are logical processor specific (TS) (see Section 18.13.4, "Performance Monitoring Events") and which are non-logical processor specific (TI).

Some of the Pentium 4 and Intel Xeon processor performance-monitoring events may be available only to specific models. The performance-monitoring events listed in Tables 19-23 and 19-24 apply to processors with CPUID signature that matches family encoding 15, model encoding 0, 1, 2 3, 4, or 6. Table  applies to processors with a CPUID signature that matches family encoding 15, model encoding 3, 4 or 6.

The functionality of performance-monitoring events in Pentium 4 and Intel Xeon processors is also available when IA-32e mode is enabled.

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| TC_deliver_mode | | | This event counts the duration (in clock cycles) of the operating modes of the trace cache and decode engine in the processor package. The mode is specified by one or more of the event mask bits. |
| | ESCR restrictions | MSR_TC_ESCR0<br>MSR_TC_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 4, 5<br>ESCR1: 6, 7 | |
| | ESCR Event Select | 01H | ESCR[31:25] |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | ESCR Event Mask | Bit | ESCR[24:9] |
| | | 0: DD | Both logical processors are in deliver mode. |
| | | 1: DB | Logical processor 0 is in deliver mode and logical processor 1 is in build mode. |
| | | 2: DI | Logical processor 0 is in deliver mode and logical processor 1 is either halted, under a machine clear condition or transitioning to a long microcode flow. |
| | | 3: BD | Logical processor 0 is in build mode and logical processor 1 is in deliver mode. |
| | | 4: BB | Both logical processors are in build mode. |
| | | 5: BI | Logical processor 0 is in build mode and logical processor 1 is either halted, under a machine clear condition or transitioning to a long microcode flow. |
| | | 6: ID | Logical processor 0 is either halted, under a machine clear condition or transitioning to a long microcode flow. Logical processor 1 is in deliver mode. |
| | | 7: IB | Logical processor 0 is either halted, under a machine clear condition or transitioning to a long microcode flow. Logical processor 1 is in build mode. |
| | CCCR Select | 01H | CCCR[15:13] |
| | Event Specific Notes | | If only one logical processor is available from a physical processor package, the event mask should be interpreted as logical processor 1 is halted. Event mask bit 2 was previously known as "DELIVER", bit 5 was previously known as "BUILD". |
| BPU_fetch_ request | | | This event counts instruction fetch requests of specified request type by the Branch Prediction unit. Specify one or more mask bits to qualify the request type(s). |
| | ESCR restrictions | MSR_BPU_ESCR0 MSR_BPU_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 0, 1 ESCR1: 2, 3 | |
| | ESCR Event Select | 03H | ESCR[31:25] |
| | ESCR Event Mask | Bit 0: TCMISS | ESCR[24:9] Trace cache lookup miss |
| | CCCR Select | 00H | CCCR[15:13] |
| ITLB_reference | | | This event counts translations using the Instruction Translation Look-aside Buffer (ITLB). |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | ESCR restrictions | MSR_ITLB_ESCR0<br>MSR_ITLB_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 0, 1<br>ESCR1: 2, 3 | |
| | ESCR Event Select | 18H | ESCR[31:25] |

| | CCCR Select | 07H | CCCR[15:13] |
| | Event Specific Notes | | 1: The implementation of this event in current Pentium 4 and Xeon processors treats either a load operation or a request for ownership (RFO) request as a "read" type operation.<br>2: Currently this event causes both over and undercounting by as much as a factor of two due to an erratum.<br>3: It is possible for a transaction that is started as a prefetch to change the transaction's internal status, making it no longer a prefetch. or change the access result status (hit, miss) as seen by this event. |
| IOQ_allocation | | | This event counts the various types of transactions on the bus. A count is generated each time a transaction is allocated into the IOQ that matches the specified mask bits. An allocated entry can be a sector (64 bytes) or a chunks of 8 bytes.<br>Requests are counted once per retry. The event mask bits constitute 4 bit fields. A transaction type is specified by interpreting the values of each bit field.<br>Specify one or more event mask bits in a bit field to select the value of the bit field.<br>Each field (bits 0-4 are one field) are independent of and can be ORed with the others. The request type field is further combined with bit 5 and 6 to form a binary expression. Bits 7 and 8 form a bit field to specify the memory type of the target address.<br>Bits 13 and 14 form a bit field to specify the source agent of the request. Bit 15 affects read operation only. The event is triggered by evaluating the logical expression: (((Request type) OR Bit 5 OR Bit 6) OR (Memory type)) AND (Source agent). |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |

| | CCCR Select | 06H | CCCR[15:13] |
| | Event Specific Notes | | 1: If PREFETCH bit is cleared, sectors fetched using prefetch are excluded in the counts. If PREFETCH bit is set, all sectors or chunks read are counted.<br><br>2: Specify the edge trigger in CCCR to avoid double counting. |
| | | | 3: The mapping of interpreted bit field values to transaction types may differ with different processor model implementations of the Pentium 4 processor family. Applications that program performance monitoring events should use CPUID to determine processor models when using this event. The logic equations that trigger the event are model-specific (see 4a and 4b below).<br><br>4a:For Pentium 4 and Xeon Processors starting with CPUID Model field encoding equal to 2 or greater, this event is triggered by evaluating the logical expression ((Request type) and (Bit 5 or Bit 6) and (Memory type) and (Source agent)).<br><br>4b:For Pentium 4 and Xeon Processors with CPUID Model field encoding less than 2, this event is triggered by evaluating the logical expression [((Request type) or Bit 5 or Bit 6) or (Memory type)] and (Source agent). Note that event mask bits for memory type are ignored if either ALL_READ or ALL_WRITE is specified. |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | | | 5: This event is known to ignore CPL in early implementations of Pentium 4 and Xeon Processors. Both user requests and OS requests are included in the count. This behavior is fixed starting with Pentium 4 and Xeon Processors with CPUID signature F27H (Family 15, Model 2, Stepping 7).<br>6: For write-through (WT) and write-protected (WP) memory types, this event counts reads as the number of 64-byte sectors. Writes are counted by individual chunks.<br>7: For uncacheable (UC) memory types, this events counts the number of 8-byte chunks allocated.<br>8: For Pentium 4 and Xeon Processors with CPUID Signature less than F27H, only MSR_FSB_ESCR0 is available. |
| IOQ_active_ entries | | | This event counts the number of entries (clipped at 15) in the IOQ that are active. An allocated entry can be a sector (64 bytes) or a chunks of 8 bytes.<br>The event must be programmed in conjunction with IOQ_allocation. Specify one or more event mask bits to select the transactions that is counted. |
| | ESCR restrictions | MSR_FSB_ESCR1 | |
| | Counter numbers per ESCR | ESCR1: 2, 3 | |
| | ESCR Event Select | 01AH | ESCR[30:25] |

| | Event Specific Notes | | 1: Specified desired mask bits in ESCR0 and ESCR1.<br>2: See the ioq_allocation event for descriptions of the mask bits.<br>3: Edge triggering should not be used when counting cycles. |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | | | 4: The mapping of interpreted bit field values to transaction types may differ across different processor model implementations of the Pentium 4 processor family. Applications that programs performance monitoring events should use the CPUID instruction to detect processor models when using this event. The logical expression that triggers this event as describe below:<br>5a:For Pentium 4 and Xeon Processors starting with CPUID MODEL field encoding equal to 2 or greater, this event is triggered by evaluating the logical expression ((Request type) and (Bit 5 or Bit 6) and (Memory type) and (Source agent)). |
| | | | 5b:For Pentium 4 and Xeon Processors starting with CPUID MODEL field encoding less than 2, this event is triggered by evaluating the logical expression [((Request type) or Bit 5 or Bit 6) or (Memory type)] and (Source agent). Event mask bits for memory type are ignored if either ALL_READ or ALL_WRITE is specified.<br>5c: This event is known to ignore CPL in the current implementations of Pentium 4 and Xeon Processors Both user requests and OS requests are included in the count. |
| | | | 6: An allocated entry can be a full line (64 bytes) or in individual chunks of 8 bytes. |
| FSB_data_ activity | | | This event increments once for each DRDY or DBSY event that occurs on the front side bus. The event allows selection of a specific DRDY or DBSY event. |
| | ESCR restrictions | MSR_FSB_ESCR0<br>MSR_FSB_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 0, 1<br>ESCR1: 2, 3 | |
| | ESCR Event Select | 17H | ESCR[31:25] |
| | ESCR Event Mask | | ESCR[24:9] |
| | | Bit 0:<br>DRDY_DRV | Count when this processor drives data onto the bus - includes writes and implicit writebacks.<br>Asserted two processor clock cycles for partial writes and 4 processor clocks (usually in consecutive bus clocks) for full line writes. |
| | | 1: DRDY_OWN | Count when this processor reads data from the bus - includes loads and some PIC transactions. Asserted two processor clock cycles for partial reads and 4 processor clocks (usually in consecutive bus clocks) for full line reads.<br>Count DRDY events that we drive.<br>Count DRDY events sampled that we own. |
| | | 2: DRDY_OTHER | Count when data is on the bus but not being sampled by the processor. It may or may not be being driven by this processor.<br>Asserted two processor clock cycles for partial transactions and 4 processor clocks (usually in consecutive bus clocks) for full line transactions. |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | | 3: DBSY_DRV | Count when this processor reserves the bus for use in the next bus cycle in order to drive data. Asserted for two processor clock cycles for full line writes and not at all for partial line writes.<br>May be asserted multiple times (in consecutive bus clocks) if we stall the bus waiting for a cache lock to complete. |
| | | 4: DBSY_OWN | Count when some agent reserves the bus for use in the next bus cycle to drive data that this processor will sample.<br>Asserted for two processor clock cycles for full line writes and not at all for partial line writes. May be asserted multiple times (all one bus clock apart) if we stall the bus for some reason. |
| | | 5:DBSY_OTHER | Count when some agent reserves the bus for use in the next bus cycle to drive data that this processor will NOT sample. It may or may not be being driven by this processor.<br>Asserted two processor clock cycles for partial transactions and 4 processor clocks (usually in consecutive bus clocks) for full line transactions. |
| | CCCR Select | 06H | CCCR[15:13] |
| | Event Specific Notes | | Specify edge trigger in the CCCR MSR to avoid double counting.<br>DRDY_OWN and DRDY_OTHER are mutually exclusive; similarly for DBSY_OWN and DBSY_OTHER. |
| BSQ_allocation | | | This event counts allocations in the Bus Sequence Unit (BSQ) according to the specified mask bit encoding. The event mask bits consist of four sub-groups:<br>▪ request type,<br>▪ request length<br>▪ memory type<br>▪ and sub-group consisting mostly of independent bits (bits 5, 6, 7, 8, 9, and 10)<br>Specify an encoding for each sub-group. |
| | ESCR restrictions | MSR_BSU_ESCR0 | |
| | Counter numbers per ESCR | ESCR0: 0, 1 | |
| | ESCR Event Select | 05H | ESCR[31:25] |
| | ESCR Event Mask | Bit<br>0: REQ_TYPE0<br>1: REQ_TYPE1<br><br><br><br><br>2: REQ_LEN0<br>3: REQ_LEN1 | ESCR[24:9]<br>Request type encoding (bit 0 and 1) are:<br>0 – Read (excludes read invalidate)<br>1 – Read invalidate<br>2 – Write (other than writebacks)<br>3 – Writeback (evicted from cache). (public)<br>Request length encoding (bit 2, 3) are:<br>0 – 0 chunks<br>1 – 1 chunks<br>3 – 8 chunks |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | | 5: REQ_IO_TYPE | Request type is input or output. |
| | | 6: REQ_LOCK_ TYPE | Request type is bus lock. |
| | | 7: REQ_CACHE_ TYPE | Request type is cacheable. |
| | | 8: REQ_SPLIT_ TYPE | Request type is a bus 8-byte chunk split across 8-byte boundary. |
| | | 9: REQ_DEM_TYPE | Request type is a demand if set. Request type is HW.SW prefetch if 0. |
| | | 10: REQ_ORD_ TYPE | Request is an ordered type. |
| | | 11: MEM_TYPE0<br>12: MEM_TYPE1<br>13: MEM_TYPE2 | Memory type encodings (bit 11-13) are:<br>0 – UC<br>1 – WC<br>4 – WT<br>5 – WP<br>6 – WB |
| | CCCR Select | 07H | CCCR[15:13] |
| | Event Specific Notes | | 1: Specify edge trigger in CCCR to avoid double counting.<br>2: A writebacks to 3rd level cache from 2nd level cache counts as a separate entry, this is in additional to the entry allocated for a request to the bus.<br>3: A read request to WB memory type results in a request to the 64-byte sector, containing the target address, followed by a prefetch request to an adjacent sector. |
| | | | 4: For Pentium 4 and Xeon processors with CPUID model encoding value equals to 0 and 1, an allocated BSQ entry includes both the demand sector and prefetched 2nd sector.<br>5: An allocated BSQ entry for a data chunk is any request less than 64 bytes.<br>6a: This event may undercount for requests of split type transactions if the data address straddled across modulo-64 byte boundary.<br>6b: This event may undercount for requests of read request of 16-byte operands from WC or UC address.<br>6c: This event may undercount WC partial requests originated from store operands that are dwords. |
| bsq_active_ entries | | | This event represents the number of BSQ entries (clipped at 15) currently active (valid) which meet the subevent mask criteria during allocation in the BSQ. Active request entries are allocated on the BSQ until de-allocated.<br>De-allocation of an entry does not necessarily imply the request is filled. This event must be programmed in conjunction with BSQ_allocation. Specify one or more event mask bits to select the transactions that is counted. |
| | ESCR restrictions | ESCR1 | |

## Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | Counter numbers per ESCR | ESCR1: 2, 3 | |
| | ESCR Event Select | 06H | ESCR[30:25] |
| | ESCR Event Mask | | ESCR[24:9] |
| | CCCR Select | 07H | CCCR[15:13] |
| | Event Specific Notes | | 1: Specified desired mask bits in ESCR0 and ESCR1.<br>2: See the BSQ_allocation event for descriptions of the mask bits.<br>3: Edge triggering should not be used when counting cycles. |
| | | | 4: This event can be used to estimate the latency of a transaction from allocation to de-allocation in the BSQ. The latency observed by BSQ_allocation includes the latency of FSB, plus additional overhead. |
| | | | 5: Additional overhead may include the time it takes to issue two requests (the sector by demand and the adjacent sector via prefetch). Since adjacent sector prefetches have lower priority that demand fetches, on a heavily used system there is a high probability that the adjacent sector prefetch will have to wait until the next bus arbitration.<br>6: For Pentium 4 and Xeon processors with CPUID model encoding value less than 3, this event is updated every clock.<br>7: For Pentium 4 and Xeon processors with CPUID model encoding value equals to 3 or 4, this event is updated every other clock. |
| SSE_input_assist | | | This event counts the number of times an assist is requested to handle problems with input operands for SSE/SSE2/SSE3 operations; most notably denormal source operands when the DAZ bit is not set. Set bit 15 of the event mask to use this event. |
| | ESCR restrictions | MSR_FIRM_ESCR0<br>MSR_FIRM_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 8, 9<br>ESCR1: 10, 11 | |
| | ESCR Event Select | 34H | ESCR[31:25] |
| | ESCR Event Mask | <br>15: ALL | ESCR[24:9]<br>Count assists for SSE/SSE2/SSE3 μops. |
| | CCCR Select | 01H | CCCR[15:13] |
| | Event Specific Notes | | 1: Not all requests for assists are actually taken. This event is known to overcount in that it counts requests for assists from instructions on the non-retired path that do not incur a performance penalty. An assist is actually taken only for non-bogus μops. Any appreciable counts for this event are an indication that the DAZ or FTZ bit should be set and/or the source code should be changed to eliminate the condition. |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | | | 2: Two common situations for an SSE/SSE2/SSE3 operation needing an assist are: (1) when a denormal constant is used as an input and the Denormals-Are-Zero (DAZ) mode is not set, (2) when the input operand uses the underflowed result of a previous SSE/SSE2/SSE3 operation and neither the DAZ nor Flush-To-Zero (FTZ) modes are set.<br>3: Enabling the DAZ mode prevents SSE/SSE2/SSE3 operations from needing assists in the first situation. Enabling the FTZ mode prevents SSE/SSE2/SSE3 operations from needing assists in the second situation. |
| packed_SP_uop | | | This event increments for each packed single-precision μop, specified through the event mask for detection. |
| | ESCR restrictions | MSR_FIRM_ESCR0<br>MSR_FIRM_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 8, 9<br>ESCR1: 10, 11 | |
| | ESCR Event Select | 08H | ESCR[31:25] |
| | ESCR Event Mask | Bit 15: ALL | ESCR[24:9]<br>Count all μops operating on packed single-precision operands. |
| | CCCR Select | 01H | CCCR[15:13] |

| | CCCR Select | 01H | CCCR[15:13] |
| | Event Specific Notes | | If an instruction contains more than one 64-bit MMX μops, each 64-bit MMX μop that is specified by the event mask will be counted. |
| 128bit_MMX_uop | | | This event increments for each integer SIMD SSE2 instruction, which operate on 128-bit SIMD operands. |
| | ESCR restrictions | MSR_FIRM_ESCR0<br>MSR_FIRM_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 8, 9<br>ESCR1: 10, 11 | |
| | ESCR Event Select | 1AH | ESCR[31:25] |
| | ESCR Event Mask | Bit 15: ALL | ESCR[24:9]<br>Count all μops operating on 128-bit SIMD integer operands in memory or XMM registers. |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | CCCR Select | 01H | CCCR[15:13] |
| | Event Specific Notes | | If an instruction contains more than one 128-bit MMX μops, each 128-bit MMX μop that is specified by the event mask will be counted. |
| x87_FP_uop | | | This event increments for each x87 floating-point μop, specified through the event mask for detection. |
| | ESCR restrictions | MSR_FIRM_ESCR0 MSR_FIRM_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 8, 9<br>ESCR1: 10, 11 | |
| | ESCR Event Select | 04H | ESCR[31:25] |
| | ESCR Event Mask | Bit 15: ALL | ESCR[24:9]<br>Count all x87 FP μops. |
| | CCCR Select | 01H | CCCR[15:13] |
| | Event Specific Notes | | 1: If an instruction contains more than one x87 FP μops, each x87 FP μop that is specified by the event mask will be counted.<br>2: This event does not count x87 FP μop for load, store, move between registers. |
| TC_misc | | | This event counts miscellaneous events detected by the TC. The counter will count twice for each occurrence. |
| | ESCR restrictions | MSR_TC_ESCR0 MSR_TC_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 4, 5<br>ESCR1: 6, 7 | |
| | ESCR Event Select | 06H | ESCR[31:25] |
| | CCCR Select | 01H | CCCR[15:13] |
| | ESCR Event Mask | Bit 4: FLUSH | ESCR[24:9]<br>Number of flushes |
| global_power _events | | | This event accumulates the time during which a processor is not stopped. |
| | ESCR restrictions | MSR_FSB_ESCR0<br>MSR_FSB_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 0, 1<br>ESCR1: 2, 3 | |
| | ESCR Event Select | 013H | ESCR[31:25] |
| | ESCR Event Mask | Bit 0: Running | ESCR[24:9]<br>The processor is active (includes the handling of HLT STPCLK and throttling. |
| | CCCR Select | 06H | CCCR[15:13] |
| tc_ms_xfer | | | This event counts the number of times that uop delivery changed from TC to MS ROM. |
| | ESCR restrictions | MSR_MS_ESCR0<br>MSR_MS_ESCR1 | |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | Counter numbers per ESCR | ESCR0: 4, 5<br>ESCR1: 6, 7 | |
| | ESCR Event Select | 05H | ESCR[31:25] |
| | ESCR Event Mask | <br>Bit 0: CISC | ESCR[24:9]<br>A TC to MS transfer occurred. |
| | CCCR Select | 0H | CCCR[15:13] |
| uop_queue_ writes | | | This event counts the number of valid uops written to the uop queue. Specify one or more mask bits to select the source type of writes. |
| | ESCR restrictions | MSR_MS_ESCR0<br>MSR_MS_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 4, 5<br>ESCR1: 6, 7 | |
| | ESCR Event Select | 09H | ESCR[31:25] |
| | ESCR Event Mask | <br>Bit<br>0: FROM_TC_ BUILD<br>1: FROM_TC_ DELIVER<br>2: FROM_ROM | ESCR[24:9]<br><br>The uops being written are from TC build mode.<br><br>The uops being written are from TC deliver mode.<br>The uops being written are from microcode ROM. |
| | CCCR Select | 0H | CCCR[15:13] |
| retired_mispred _branch_type | | | This event counts retiring mispredicted branches by type. |
| | ESCR restrictions | MSR_TBPU_ESCR0<br>MSR_TBPU_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 4, 5<br>ESCR1: 6, 7 | |
| | ESCR Event Select | 05H | ESCR[30:25] |
| | ESCR Event Mask | <br>Bit<br>1: CONDITIONAL<br>2: CALL | ESCR[24:9]<br><br>Conditional jumps.<br>Indirect call branches. |
| | | 3: RETURN<br>4: INDIRECT | Return branches.<br>Returns, indirect calls, or indirect jumps. |
| | CCCR Select | 02H | CCCR[15:13] |
| | Event Specific Notes | | This event may overcount conditional branches if:<br>▪ Mispredictions cause the trace cache and delivery engine to build new traces.<br>▪ When the processor's pipeline is being cleared. |
| retired_branch _type | | | This event counts retiring branches by type. Specify one or more mask bits to qualify the branch by its type. |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | ESCR restrictions | MSR_TBPU_ESCR0<br>MSR_TBPU_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 4, 5<br>ESCR1: 6, 7 | |
| | ESCR Event Select | 04H | ESCR[30:25] |
| | ESCR Event Mask | Bit<br>1: CONDITIONAL<br>2: CALL<br>3: RETURN<br>4: INDIRECT | ESCR[24:9]<br>Conditional jumps.<br>Direct or indirect calls.<br>Return branches.<br>Returns, indirect calls, or indirect jumps. |
| | CCCR Select | 02H | CCCR[15:13] |
| | Event Specific Notes | | This event may overcount conditional branches if :<br>▪ Mispredictions cause the trace cache and delivery engine to build new traces.<br>▪ When the processor's pipeline is being cleared. |
| resource_stall | | | This event monitors the occurrence or latency of stalls in the Allocator. |
| | ESCR restrictions | MSR_ALF_ESCR0<br>MSR_ALF_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 12, 13, 16<br>ESCR1: 14, 15, 17 | |
| | ESCR Event Select | 01H | ESCR[30:25] |
| | Event Masks | Bit<br>5: SBFULL | ESCR[24:9]<br>A Stall due to lack of store buffers. |
| | CCCR Select | 01H | CCCR[15:13] |
| | Event Specific Notes | | This event may not be supported in all models of the processor family. |
| WC_Buffer | | | This event counts Write Combining Buffer operations that are selected by the event mask. |
| | ESCR restrictions | MSR_DAC_ESCR0<br>MSR_DAC_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 8, 9<br>ESCR1: 10, 11 | |
| | ESCR Event Select | 05H | ESCR[30:25] |
| | Event Masks | Bit<br>0: WCB_EVICTS | ESCR[24:9]<br>WC Buffer evictions of all causes. |
| | | 1: WCB_FULL_ EVICT | WC Buffer eviction: no WC buffer is available. |

**Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | CCCR Select | 05H | CCCR[15:13] |
| | Event Specific Notes | | This event is useful for detecting the subset of 64K aliasing cases that are more costly (i.e. 64K aliasing cases involving stores) as long as there are no significant contributions due to write combining buffer full or hit-modified conditions. |
| b2b_cycles | | | This event can be configured to count the number back-to-back bus cycles using sub-event mask bits 1 through 6. |
| | ESCR restrictions | MSR_FSB_ESCR0<br>MSR_FSB_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 0, 1<br>ESCR1: 2, 3 | |
| | ESCR Event Select | 016H | ESCR[30:25] |
| | Event Masks | Bit | ESCR[24:9] |
| | CCCR Select | 03H | CCCR[15:13] |
| | Event Specific Notes | | This event may not be supported in all models of the processor family. |
| bnr | | | This event can be configured to count bus not ready conditions using sub-event mask bits 0 through 2. |
| | ESCR restrictions | MSR_FSB_ESCR0<br>MSR_FSB_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 0, 1<br>ESCR1: 2, 3 | |
| | ESCR Event Select | 08H | ESCR[30:25] |
| | Event Masks | Bit | ESCR[24:9] |
| | CCCR Select | 03H | CCCR[15:13] |
| | Event Specific Notes | | This event may not be supported in all models of the processor family. |
| snoop | | | This event can be configured to count snoop hit modified bus traffic using sub-event mask bits 2, 6 and 7. |
| | ESCR restrictions | MSR_FSB_ESCR0<br>MSR_FSB_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 0, 1<br>ESCR1: 2, 3 | |
| | ESCR Event Select | 06H | ESCR[30:25] |
| | Event Masks | Bit | ESCR[24:9] |
| | CCCR Select | 03H | CCCR[15:13] |
| | Event Specific Notes | | This event may not be supported in all models of the processor family. |
| Response | | | This event can be configured to count different types of responses using sub-event mask bits 1,2, 8, and 9. |
| | ESCR restrictions | MSR_FSB_ESCR0<br>MSR_FSB_ESCR1 | |

### Table 19-23. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | Counter numbers per ESCR | ESCR0: 0, 1<br>ESCR1: 2, 3 | |
| | ESCR Event Select | 04H | ESCR[30:25] |
| | Event Masks | Bit | ESCR[24:9] |
| | CCCR Select | 03H | CCCR[15:13] |
| | Event Specific Notes | | This event may not be supported in all models of the processor family. |

### Table 19-24. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| front_end_event | | | This event counts the retirement of tagged μops, which are specified through the front-end tagging mechanism. The event mask specifies bogus or non-bogus μops. |
| | ESCR restrictions | MSR_CRU_ESCR2<br>MSR_CRU_ESCR3 | |
| | Counter numbers per ESCR | ESCR2: 12, 13, 16<br>ESCR3: 14, 15, 17 | |
| | ESCR Event Select | 08H | ESCR[31:25] |
| | ESCR Event Mask | <br>Bit<br>0: NBOGUS<br>1: BOGUS | ESCR[24:9]<br><br>The marked μops are not bogus.<br>The marked μops are bogus. |
| | CCCR Select | 05H | CCCR[15:13] |
| | Can Support PEBS | Yes | |
| | Require Additional MSRs for tagging | Selected ESCRs and/or MSR_TC_ PRECISE_EVENT | See list of metrics supported by Front_end tagging in Table A-3 |
| execution_event | | | This event counts the retirement of tagged μops, which are specified through the execution tagging mechanism.<br>The event mask allows from one to four types of μops to be specified as either bogus or non-bogus μops to be tagged. |
| | ESCR restrictions | MSR_CRU_ESCR2<br>MSR_CRU_ESCR3 | |
| | Counter numbers per ESCR | ESCR2: 12, 13, 16<br>ESCR3: 14, 15, 17 | |
| | ESCR Event Select | 0CH | ESCR[31:25] |

**Table 19-24. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | ESCR Event Mask | Bit<br>0: NBOGUS0<br>1: NBOGUS1<br>2: NBOGUS2<br>3: NBOGUS3<br>4: BOGUS0<br>5: BOGUS1<br>6: BOGUS2<br>7: BOGUS3 | ESCR[24:9]<br><br>The marked μops are not bogus.<br>The marked μops are not bogus.<br>The marked μops are not bogus.<br>The marked μops are not bogus.<br>The marked μops are bogus.<br>The marked μops are bogus.<br>The marked μops are bogus.<br>The marked μops are bogus. |
| | CCCR Select | 05H | CCCR[15:13] |
| | Event Specific Notes | | Each of the 4 slots to specify the bogus/non-bogus μops must be coordinated with the 4 TagValue bits in the ESCR (for example, NBOGUS0 must accompany a '1' in the lowest bit of the TagValue field in ESCR, NBOGUS1 must accompany a '1' in the next but lowest bit of the TagValue field). |
| | Can Support PEBS | Yes | |
| | Require Additional MSRs for tagging | An ESCR for an upstream event | See list of metrics supported by execution tagging in Table A-4. |
| replay_event | | | This event counts the retirement of tagged μops, which are specified through the replay tagging mechanism. The event mask specifies bogus or non-bogus μops. |
| | ESCR restrictions | MSR_CRU_ESCR2<br>MSR_CRU_ESCR3 | |
| | Counter numbers per ESCR | ESCR2: 12, 13, 16<br>ESCR3: 14, 15, 17 | |
| | ESCR Event Select | 09H | ESCR[31:25] |
| | ESCR Event Mask | Bit<br>0: NBOGUS<br>1: BOGUS | ESCR[24:9]<br><br>The marked μops are not bogus.<br>The marked μops are bogus. |
| | CCCR Select | 05H | CCCR[15:13] |
| | Event Specific Notes | | Supports counting tagged μops with additional MSRs. |
| | Can Support PEBS | Yes | |
| | Require Additional MSRs for tagging | IA32_PEBS_ ENABLE<br>MSR_PEBS_ MATRIX_VERT<br>Selected ESCR | See list of metrics supported by replay tagging in Table A-5. |
| instr_retired | | | This event counts instructions that are retired during a clock cycle.<br>Mask bits specify bogus or non-bogus (and whether they are tagged using the front-end tagging mechanism). |

**Table 19-24. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | ESCR restrictions | MSR_CRU_ESCR0<br>MSR_CRU_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 12, 13, 16<br>ESCR1: 14, 15, 17 | |
| | ESCR Event Select | 02H | ESCR[31:25] |
| | ESCR Event Mask | <br>Bit<br>0: NBOGUSNTAG<br><br>1: NBOGUSTAG<br>2: BOGUSNTAG<br><br>3: BOGUSTAG | ESCR[24:9]<br><br>Non-bogus instructions that are not tagged.<br>Non-bogus instructions that are tagged.<br><br>Bogus instructions that are not tagged.<br>Bogus instructions that are tagged. |
| | CCCR Select | 04H | CCCR[15:13] |
| | Event Specific Notes | | 1: The event count may vary depending on the microarchitectural states of the processor when the event detection is enabled.<br>2: The event may count more than once for some instructions with complex uop flows and were interrupted before retirement. |
| | Can Support PEBS | No | |
| uops_retired | | | This event counts μops that are retired during a clock cycle. Mask bits specify bogus or non-bogus. |
| | ESCR restrictions | MSR_CRU_ESCR0<br>MSR_CRU_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 12, 13, 16<br>ESCR1: 14, 15, 17 | |
| | ESCR Event Select | 01H | ESCR[31:25] |
| | ESCR Event Mask | <br>Bit<br>0: NBOGUS<br>1: BOGUS | ESCR[24:9]<br><br>The marked μops are not bogus.<br>The marked μops are bogus. |
| | CCCR Select | 04H | CCCR[15:13] |
| | Event Specific Notes | | P6: EMON_UOPS_RETIRED |
| | Can Support PEBS | No | |
| uop_type | | | This event is used in conjunction with the front-end at-retirement mechanism to tag load and store μops. |
| | ESCR restrictions | MSR_RAT_ESCR0<br>MSR_RAT_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 12, 13, 16<br>ESCR1: 14, 15, 17 | |
| | ESCR Event Select | 02H | ESCR[31:25] |

## Table 19-24. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting (Contd.)

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | ESCR Event Mask | Bit<br>1: TAGLOADS<br>2: TAGSTORES | ESCR[24:9]<br>The μop is a load operation.<br>The μop is a store operation. |
| | CCCR Select | 02H | CCCR[15:13] |
| | Event Specific Notes | | Setting the TAGLOADS and TAGSTORES mask bits does not cause a counter to increment. They are only used to tag uops. |
| | Can Support PEBS | No | |
| branch_retired | | | This event counts the retirement of a branch. Specify one or more mask bits to select any combination of taken, not-taken, predicted and mispredicted. |
| | ESCR restrictions | MSR_CRU_ESCR2<br>MSR_CRU_ESCR3 | See Table 18-45 for the addresses of the ESCR MSRs |
| | Counter numbers per ESCR | ESCR2: 12, 13, 16<br>ESCR3: 14, 15, 17 | The counter numbers associated with each ESCR are provided. The performance counters and corresponding CCCRs can be obtained from Table 18-45. |
| | ESCR Event Select | 06H | ESCR[31:25] |
| | ESCR Event Mask | Bit<br>0: MMNP<br>1: MMNM<br>2: MMTP<br>3: MMTM | ESCR[24:9]<br>Branch not-taken predicted<br>Branch not-taken mispredicted<br>Branch taken predicted<br>Branch taken mispredicted |
| | | | |
| | CCCR Select | 05H | CCCR[15:13] |
| | Event Specific Notes | | P6: EMON_BR_INST_RETIRED |
| | Can Support PEBS | No | |
| mispred_branch_ retired | | | This event represents the retirement of mispredicted branch instructions. |
| | ESCR restrictions | MSR_CRU_ESCR0<br>MSR_CRU_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 12, 13, 16<br>ESCR1: 14, 15, 17 | |
| | ESCR Event Select | 03H | ESCR[31:25] |
| | ESCR Event Mask | Bit 0: NBOGUS | ESCR[24:9]<br>The retired instruction is not bogus. |
| | CCCR Select | 04H | CCCR[15:13] |
| | Can Support PEBS | No | |
| x87_assist | | | This event counts the retirement of x87 instructions that required special handling.<br>Specifies one or more event mask bits to select the type of assistance. |

**Table 19-24. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting (Contd.)**

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| | ESCR restrictions | MSR_CRU_ESCR2<br>MSR_CRU_ESCR3 | |
| | Counter numbers per ESCR | ESCR2: 12, 13, 16<br>ESCR3: 14, 15, 17 | |
| | ESCR Event Select | 03H | ESCR[31:25] |
| | ESCR Event Mask | <br>Bit<br>0: FPSU<br>1: FPSO<br>2: POAO<br>3: POAU<br>4: PREA | ESCR[24:9]<br><br>Handle FP stack underflow<br>Handle FP stack overflow<br>Handle x87 output overflow<br>Handle x87 output underflow<br>Handle x87 input assist |
| | CCCR Select | 05H | CCCR[15:13] |
| | Can Support PEBS | No | |
| machine_clear | | | This event increments according to the mask bit specified while the entire pipeline of the machine is cleared. Specify one of the mask bit to select the cause. |
| | ESCR restrictions | MSR_CRU_ESCR2<br>MSR_CRU_ESCR3 | |
| | Counter numbers per ESCR | ESCR2: 12, 13, 16<br>ESCR3: 14, 15, 17 | |
| | ESCR Event Select | 02H | ESCR[31:25] |
| | ESCR Event Mask | <br>Bit<br>0: CLEAR<br><br>2: MOCLEAR<br><br>6: SMCLEAR | ESCR[24:9]<br><br>Counts for a portion of the many cycles while the machine is cleared for any cause. Use Edge triggering for this bit only to get a count of occurrence versus a duration.<br>Increments each time the machine is cleared due to memory ordering issues.<br>Increments each time the machine is cleared due to self-modifying code issues. |
| | CCCR Select | 05H | CCCR[15:13] |
| | Can Support PEBS | No | |

### Table 19-25. Intel NetBurst® Microarchitecture Model-Specific Performance Monitoring Events (For Model Encoding 3, 4 or 6)

| Event Name | Event Parameters | Parameter Value | Description |
|---|---|---|---|
| instr_completed | | | This event counts instructions that have completed and retired during a clock cycle. Mask bits specify whether the instruction is bogus or non-bogus and whether they are: |
| | ESCR restrictions | MSR_CRU_ESCR0<br>MSR_CRU_ESCR1 | |
| | Counter numbers per ESCR | ESCR0: 12, 13, 16<br>ESCR1: 14, 15, 17 | |
| | ESCR Event Select | 07H | ESCR[31:25] |
| | ESCR Event Mask | <br>Bit<br>0: NBOGUS<br>1: BOGUS | ESCR[24:9]<br><br>Non-bogus instructions<br>Bogus instructions |
| | CCCR Select | 04H | CCCR[15:13] |
| | Event Specific Notes | | This metric differs from instr_retired, since it counts instructions completed, rather than the number of times that instructions started. |
| | Can Support PEBS | No | |

### Table 19-26. List of Metrics Available for Front_end Tagging (For Front_end Event Only)

| Front-end metric[1] | MSR_ TC_PRECISE_EVENT MSR Bit field | Additional MSR | Event mask value for Front_end_event |
|---|---|---|---|
| memory_loads | None | Set TAGLOADS bit in ESCR corresponding to event Uop_Type. | NBOGUS |
| memory_stores | None | Set TAGSTORES bit in the ESCR corresponding to event Uop_Type. | NBOGUS |

**NOTES:**

1. There may be some undercounting of front end events when there is an overflow or underflow of the floating point stack.

### Table 19-27. List of Metrics Available for Execution Tagging (For Execution Event Only)

| Execution metric | Upstream ESCR | TagValue in Upstream ESCR | Event mask value for execution_event |
|---|---|---|---|
| packed_SP_retired | Set ALL bit in event mask, TagUop bit in ESCR of packed_SP_uop. | 1 | NBOGUS0 |
| packed_DP_retired | Set ALL bit in event mask, TagUop bit in ESCR of packed_DP_uop. | 1 | NBOGUS0 |
| scalar_SP_retired | Set ALL bit in event mask, TagUop bit in ESCR of scalar_SP_uop. | 1 | NBOGUS0 |
| scalar_DP_retired | Set ALL bit in event mask, TagUop bit in ESCR of scalar_DP_uop. | 1 | NBOGUS0 |
| 128_bit_MMX_retired | Set ALL bit in event mask, TagUop bit in ESCR of 128_bit_MMX_uop. | 1 | NBOGUS0 |
| 64_bit_MMX_retired | Set ALL bit in event mask, TagUop bit in ESCR of 64_bit_MMX_uop. | 1 | NBOGUS0 |

### Table 19-27. List of Metrics Available for Execution Tagging (For Execution Event Only) (Contd.)

| Execution metric | Upstream ESCR | TagValue in Upstream ESCR | Event mask value for execution_event |
|---|---|---|---|
| X87_FP_retired | Set ALL bit in event mask, TagUop bit in ESCR of x87_FP_uop. | 1 | NBOGUS0 |
| X87_SIMD_memory_moves_retired | Set ALLP0, ALLP2 bits in event mask, TagUop bit in ESCR of X87_SIMD_ moves_uop. | 1 | NBOGUS0 |

### Table 19-28. List of Metrics Available for Replay Tagging (For Replay Event Only)

| Replay metric[1] | IA32_PEBS_ ENABLE Field to Set | MSR_PEBS_ MATRIX_VERT Bit Field to Set | Additional MSR/ Event | Event Mask Value for Replay_event |
|---|---|---|---|---|
| 1stL_cache_load _miss_retired | Bit 0, Bit 24, Bit 25 | Bit 0 | None | NBOGUS |
| 2ndL_cache_load _miss_retired[2] | Bit 1, Bit 24, Bit 25 | Bit 0 | None | NBOGUS |
| DTLB_load_miss _retired | Bit 2, Bit 24, Bit 25 | Bit 0 | None | NBOGUS |
| DTLB_store_miss _retired | Bit 2, Bit 24, Bit 25 | Bit 1 | None | NBOGUS |
| DTLB_all_miss _retired | Bit 2, Bit 24, Bit 25 | Bit 0, Bit 1 | None | NBOGUS |
| Tagged_mispred_ branch | Bit 15, Bit 16, Bit 24, Bit 25 | Bit 4 | None | NBOGUS |
| MOB_load _replay_retired[3] | Bit 9, Bit 24, Bit 25 | Bit 0 | Select MOB_load_replay event and set PARTIAL_DATA and UNALGN_ADDR bit. | NBOGUS |
| split_load_retired | Bit 10, Bit 24, Bit 25 | Bit 0 | Select load_port_replay event with the MSR_SAAT_ESCR1 MSR and set the SPLIT_LD mask bit. | NBOGUS |
| split_store_retired | Bit 10, Bit 24, Bit 25 | Bit 1 | Select store_port_replay event with the MSR_SAAT_ESCR0 MSR and set the SPLIT_ST mask bit. | NBOGUS |

**NOTES:**

1. Certain kinds of μops cannot be tagged. These include I/O operations, UC and locked accesses, returns, and far transfers.
2. 2nd-level misses retired does not count all 2nd-level misses. It only includes those references that are found to be misses by the fast detection logic and not those that are later found to be misses.
3. While there are several causes for a MOB replay, the event counted with this event mask setting is the case where the data from a load that would otherwise be forwarded is not an aligned subset of the data from a preceding store.

## 19.14 PERFORMANCE MONITORING EVENTS FOR INTEL® PENTIUM® M PROCESSORS

The Pentium M processor's performance-monitoring events are based on monitoring events for the P6 family of processors. All of these performance events are model specific for the Pentium M processor and are not available in this form in other processors. Table 19-30 lists the Performance-Monitoring events that were added in the Pentium M processor.

### Table 19-30. Performance Monitoring Events on Intel® Pentium® M Processors

| Name | Hex Values | Descriptions |
|---|---|---|
| Power Management | | |
| EMON_EST_TRANS | 58H | Number of Enhanced Intel SpeedStep technology transitions:<br>Mask = 00H - All transitions<br>Mask = 02H - Only Frequency transitions |
| EMON_THERMAL_TRIP | 59H | Duration/Occurrences in thermal trip; to count number of thermal trips: bit 22 in PerfEvtSel0/1 needs to be set to enable edge detect. |
| BPU | | |
| BR_INST_EXEC | 88H | Branch instructions that were executed (not necessarily retired). |
| BR_MISSP_EXEC | 89H | Branch instructions executed that were mispredicted at execution. |
| BR_BAC_MISSP_EXEC | 8AH | Branch instructions executed that were mispredicted at front end (BAC). |
| BR_CND_EXEC | 8BH | Conditional branch instructions that were executed. |
| BR_CND_MISSP_EXEC | 8CH | Conditional branch instructions executed that were mispredicted. |
| BR_IND_EXEC | 8DH | Indirect branch instructions executed. |
| BR_IND_MISSP_EXEC | 8EH | Indirect branch instructions executed that were mispredicted. |
| BR_RET_EXEC | 8FH | Return branch instructions executed. |
| BR_RET_MISSP_EXEC | 90H | Return branch instructions executed that were mispredicted at execution. |
| BR_RET_BAC_MISSP_EXEC | 91H | Return branch instructions executed that were mispredicted at front end (BAC). |
| BR_CALL_EXEC | 92H | CALL instruction executed. |
| BR_CALL_MISSP_EXEC | 93H | CALL instruction executed and miss predicted. |
| BR_IND_CALL_EXEC | 94H | Indirect CALL instructions executed. |
| Decoder | | |
| EMON_SIMD_INSTR_RETIRED | CEH | Number of retired MMX instructions. |
| EMON_SYNCH_UOPS | D3H | Sync micro-ops |
| EMON_ESP_UOPS | D7H | Total number of micro-ops |
| EMON_FUSED_UOPS_RET | DAH | Number of retired fused micro-ops:<br>Mask = 0 - Fused micro-ops<br>Mask = 1 - Only load+Op micro-ops<br>Mask = 2 - Only std+sta micro-ops |
| EMON_UNFUSION | DBH | Number of unfusion events in the ROB, happened on a FP exception to a fused $\mu$op. |
| Prefetcher | | |
| EMON_PREF_RQSTS_UP | F0H | Number of upward prefetches issued |
| EMON_PREF_RQSTS_DN | F8H | Number of downward prefetches issued |

A number of P6 family processor performance monitoring events are modified for the Pentium M processor. Table 19-31 lists the performance monitoring events that were changed in the Pentium M processor, and differ from performance monitoring events for the P6 family of processors.

**Table 19-31. Performance Monitoring Events Modified on Intel® Pentium® M Processors**

| Name | Hex Values | Descriptions | |
|---|---|---|---|
| CPU_CLK_UNHALTED | 79H | Number of cycles during which the processor is not halted, and not in a thermal trip. | |
| EMON_SSE_SSE2_INST_ RETIRED | D8H | Streaming SIMD Extensions Instructions Retired:<br>Mask = 0 – SSE packed single and scalar single<br>Mask = 1 – SSE scalar-single<br>Mask = 2 – SSE2 packed-double<br>Mask = 3 – SSE2 scalar-double | |
| EMON_SSE_SSE2_COMP_INST_ RETIRED | D9H | Computational SSE Instructions Retired:<br>Mask = 0 – SSE packed single<br>Mask = 1 – SSE Scalar-single<br>Mask = 2 – SSE2 packed-double<br>Mask = 3 – SSE2 scalar-double | |
| L2_LD | 29H | L2 data loads | Mask[0] = 1 – count I state lines<br>Mask[1] = 1 – count S state lines<br>Mask[2] = 1 – count E state lines<br>Mask[3] = 1 – count M state lines<br>Mask[5:4]:<br>00H – Excluding hardware-prefetched lines<br>01H - Hardware-prefetched lines only<br>02H/03H – All (HW-prefetched lines and non HW -- Prefetched lines) |
| L2_LINES_IN | 24H | L2 lines allocated | |
| L2_LINES_OUT | 26H | L2 lines evicted | |
| L2_M_LINES_OUT | 27H | Lw M-state lines evicted | |

## 19.15 P6 FAMILY PROCESSOR PERFORMANCE-MONITORING EVENTS

Table 19-32 lists the events that can be counted with the performance-monitoring counters and read with the RDPMC instruction for the P6 family processors. The unit column gives the microarchitecture or bus unit that produces the event; the event number column gives the hexadecimal number identifying the event; the mnemonic event name column gives the name of the event; the unit mask column gives the unit mask required (if any); the description column describes the event; and the comments column gives additional information about the event.

All of these performance events are model specific for the P6 family processors and are not available in this form in the Pentium 4 processors or the Pentium processors. Some events (such as those added in later generations of the P6 family processors) are only available in specific processors in the P6 family. All performance event encodings not listed in Table 19-32 are reserved and their use will result in undefined counter results.

See the end of the table for notes related to certain entries in the table.

### Table 19-32. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description | Comments |
|---|---|---|---|---|---|
| Data Cache Unit (DCU) | 43H | DATA_MEM_REFS | 00H | All loads from any memory type. All stores to any memory type. Each part of a split is counted separately. The internal logic counts not only memory loads and stores, but also internal retries.<br>80-bit floating-point accesses are double counted, since they are decomposed into a 16-bit exponent load and a 64-bit mantissa load. Memory accesses are only counted when they are actually performed (such as a load that gets squashed because a previous cache miss is outstanding to the same address, and which finally gets performed, is only counted once).<br>Does not include I/O accesses, or other nonmemory accesses. | |
| | 45H | DCU_LINES_IN | 00H | Total lines allocated in DCU. | |
| | 46H | DCU_M_LINES_IN | 00H | Number of M state lines allocated in DCU. | |
| | 47H | DCU_M_LINES_ OUT | 00H | Number of M state lines evicted from DCU.<br>This includes evictions via snoop HITM, intervention or replacement. | |
| | 48H | DCU_MISS_ OUTSTANDING | 00H | Weighted number of cycles while a DCU miss is outstanding, incremented by the number of outstanding cache misses at any particular time.<br>Cacheable read requests only are considered.<br>Uncacheable requests are excluded.<br>Read-for-ownerships are counted, as well as line fills, invalidates, and stores. | An access that also misses the L2 is short-changed by 2 cycles (i.e., if counts N cycles, should be N+2 cycles).<br>Subsequent loads to the same cache line will not result in any additional counts.<br>Count value not precise, but still useful. |
| Instruction Fetch Unit (IFU) | 80H | IFU_IFETCH | 00H | Number of instruction fetches, both cacheable and noncacheable, including UC fetches. | |
| | 81H | IFU_IFETCH_ MISS | 00H | Number of instruction fetch misses<br>All instruction fetches that do not hit the IFU (i.e., that produce memory requests). This includes UC accesses. | |
| | 85H | ITLB_MISS | 00H | Number of ITLB misses. | |
| | 86H | IFU_MEM_STALL | 00H | Number of cycles instruction fetch is stalled, for any reason.<br>Includes IFU cache misses, ITLB misses, ITLB faults, and other minor stalls. | |
| | 87H | ILD_STALL | 00H | Number of cycles that the instruction length decoder is stalled. | |
| L2 Cache[1] | 28H | L2_IFETCH | MESI 0FH | Number of L2 instruction fetches.<br>This event indicates that a normal instruction fetch was received by the L2. | |

Table 19-32. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description | Comments |
|---|---|---|---|---|---|
| | | | | The count includes only L2 cacheable instruction fetches; it does not include UC instruction fetches.<br>It does not include ITLB miss accesses. | |
| | 29H | L2_LD | MESI 0FH | Number of L2 data loads.<br>This event indicates that a normal, unlocked, load memory access was received by the L2.<br>It includes only L2 cacheable memory accesses; it does not include I/O accesses, other nonmemory accesses, or memory accesses such as UC/WT memory accesses.<br>It does include L2 cacheable TLB miss memory accesses. | |
| | 2AH | L2_ST | MESI 0FH | Number of L2 data stores.<br>This event indicates that a normal, unlocked, store memory access was received by the L2.<br>it indicates that the DCU sent a read-for-ownership request to the L2. It also includes Invalid to Modified requests sent by the DCU to the L2.<br>It includes only L2 cacheable memory accesses; it does not include I/O accesses, other nonmemory accesses, or memory accesses such as UC/WT memory accesses.<br>It includes TLB miss memory accesses. | |
| | 24H | L2_LINES_IN | 00H | Number of lines allocated in the L2. | |
| | 26H | L2_LINES_OUT | 00H | Number of lines removed from the L2 for any reason. | |
| | 25H | L2_M_LINES_INM | 00H | Number of modified lines allocated in the L2. | |
| | 27H | L2_M_LINES_ OUTM | 00H | Number of modified lines removed from the L2 for any reason. | |
| | 2EH | L2_RQSTS | MESI 0FH | Total number of L2 requests. | |
| | 21H | L2_ADS | 00H | Number of L2 address strobes. | |
| | 22H | L2_DBUS_BUSY | 00H | Number of cycles during which the L2 cache data bus was busy. | |
| | 23H | L2_DBUS_BUSY_ RD | 00H | Number of cycles during which the data bus was busy transferring read data from L2 to the processor. | |
| External Bus Logic (EBL)[2] | 62H | BUS_DRDY_ CLOCKS | 00H (Self)<br>20H (Any) | Number of clocks during which DRDY# is asserted.<br>Utilization of the external system data bus during data transfers. | Unit Mask = 00H counts bus clocks when the processor is driving DRDY#.<br>Unit Mask = 20H counts in processor clocks when any agent is driving DRDY#. |

**Table 19-32. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description | Comments |
|---|---|---|---|---|---|
| | 63H | BUS_LOCK_ CLOCKS | 00H (Self)<br>20H (Any) | Number of clocks during which LOCK# is asserted on the external system bus.[3] | Always counts in processor clocks. |
| | 60H | BUS_REQ_ OUTSTANDING | 00H (Self) | Number of bus requests outstanding.<br>This counter is incremented by the number of cacheable read bus requests outstanding in any given cycle. | Counts only DCU full-line cacheable reads, not RFOs, writes, instruction fetches, or anything else. Counts "waiting for bus to complete" (last data chunk received). |
| | 65H | BUS_TRAN_BRD | 00H (Self)<br>20H (Any) | Number of burst read transactions. | |
| | 66H | BUS_TRAN_RFO | 00H (Self)<br>20H (Any) | Number of completed read for ownership transactions. | |
| | 67H | BUS_TRANS_WB | 00H (Self)<br>20H (Any) | Number of completed write back transactions. | |
| | 68H | BUS_TRAN_ IFETCH | 00H (Self)<br>20H (Any) | Number of completed instruction fetch transactions. | |
| | 69H | BUS_TRAN_INVA L | 00H (Self)<br>20H (Any) | Number of completed invalidate transactions. | |
| | 6AH | BUS_TRAN_PWR | 00H (Self)<br>20H (Any) | Number of completed partial write transactions. | |
| | 6BH | BUS_TRANS_P | 00H (Self)<br>20H (Any) | Number of completed partial transactions. | |
| | 6CH | BUS_TRANS_IO | 00H (Self)<br>20H (Any) | Number of completed I/O transactions. | |
| | 6DH | BUS_TRAN_DEF | 00H (Self)<br>20H (Any) | Number of completed deferred transactions. | |

**Table 19-32. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description | Comments |
|---|---|---|---|---|---|
| | 6EH | BUS_TRAN_ BURST | 00H (Self)<br>20H (Any) | Number of completed burst transactions. | |
| | 70H | BUS_TRAN_ANY | 00H (Self)<br>20H (Any) | Number of all completed bus transactions.<br>Address bus utilization can be calculated knowing the minimum address bus occupancy.<br>Includes special cycles, etc. | |
| | 6FH | BUS_TRAN_MEM | 00H (Self)<br>20H (Any) | Number of completed memory transactions. | |
| | 64H | BUS_DATA_RCV | 00H (Self) | Number of bus clock cycles during which this processor is receiving data. | |
| | 61H | BUS_BNR_DRV | 00H (Self) | Number of bus clock cycles during which this processor is driving the BNR# pin. | |
| | 7AH | BUS_HIT_DRV | 00H (Self) | Number of bus clock cycles during which this processor is driving the HIT# pin. | Includes cycles due to snoop stalls.<br>The event counts correctly, but BPM*i* (breakpoint monitor) pins function as follows based on the setting of the PC bits (bit 19 in the PerfEvtSel0 and PerfEvtSel1 registers):<br>▪ If the core-clock-to- bus-clock ratio is 2:1 or 3:1, and a PC bit is set, the BPM*i* pins will be asserted for a single clock when the counters overflow.<br>▪ If the PC bit is clear, the processor toggles the BPM*i* pins when the counter overflows.<br>▪ If the clock ratio is not 2:1 or 3:1, the BPM*i* pins will not function for these performance-monitoring counter events. |
| | 7BH | BUS_HITM_DRV | 00H (Self) | Number of bus clock cycles during which this processor is driving the HITM# pin. | Includes cycles due to snoop stalls.<br>The event counts correctly, but BPM*i* (breakpoint monitor) pins function as follows based on the setting of the PC bits (bit 19 in the PerfEvtSel0 and PerfEvtSel1 registers):<br>▪ If the core-clock-to- bus-clock ratio is 2:1 or 3:1, and a PC bit is set, the BPM*i* pins will be asserted for a single clock when the counters overflow. |

**Table 19-32. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description | Comments |
|---|---|---|---|---|---|
| | | | | | ▪ If the PC bit is clear, the processor toggles the BPM*i*pins when the counter overflows.<br>▪ If the clock ratio is not 2:1 or 3:1, the BPM*i* pins will not function for these performance-monitoring counter events. |
| | 7EH | BUS_SNOOP_ STALL | 00H (Self) | Number of clock cycles during which the bus is snoop stalled. | |
| Floating-Point Unit | C1H | FLOPS | 00H | Number of computational floating-point operations retired.<br>Excludes floating-point computational operations that cause traps or assists.<br>Includes floating-point computational operations executed by the assist handler.<br>Includes internal sub-operations for complex floating-point instructions like transcendentals.<br>Excludes floating-point loads and stores. | Counter 0 only. |
| | 10H | FP_COMP_OPS_ EXE | 00H | Number of computational floating-point operations executed.<br>The number of FADD, FSUB, FCOM, FMULs, integer MULs and IMULs, FDIVs, FPREMs, FSQRTS, integer DIVs, and IDIVs.<br>This number does not include the number of cycles, but the number of operations.<br>This event does not distinguish an FADD used in the middle of a transcendental flow from a separate FADD instruction. | Counter 0 only. |
| | 11H | FP_ASSIST | 00H | Number of floating-point exception cases handled by microcode. | Counter 1 only.<br>This event includes counts due to speculative execution. |
| | 12H | MUL | 00H | Number of multiplies.<br>This count includes integer as well as FP multiplies and is speculative. | Counter 1 only. |
| | 13H | DIV | 00H | Number of divides.<br>This count includes integer as well as FP divides and is speculative. | Counter 1 only. |
| | 14H | CYCLES_DIV_ BUSY | 00H | Number of cycles during which the divider is busy, and cannot accept new divides.<br>This includes integer and FP divides, FPREM, FPSQRT, etc. and is speculative. | Counter 0 only. |

**Table 19-32. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description | Comments |
|---|---|---|---|---|---|
| Memory Ordering | 03H | LD_BLOCKS | 00H | Number of load operations delayed due to store buffer blocks.<br>Includes counts caused by preceding stores whose addresses are unknown, preceding stores whose addresses are known but whose data is unknown, and preceding stores that conflicts with the load but which incompletely overlap the load. | |
| | 04H | SB_DRAINS | 00H | Number of store buffer drain cycles.<br>Incremented every cycle the store buffer is draining.<br>Draining is caused by serializing operations like CPUID, synchronizing operations like XCHG, interrupt acknowledgment, as well as other conditions (such as cache flushing). | |
| | 05H | MISALIGN_ MEM_REF | 00H | Number of misaligned data memory references.<br>Incremented by 1 every cycle, during which either the processor's load or store pipeline dispatches a misaligned μop.<br>Counting is performed if it is the first or second half, or if it is blocked, squashed, or missed.<br>In this context, misaligned means crossing a 64-bit boundary. | MISALIGN_MEM_ REF is only an approximation to the true number of misaligned memory references.<br>The value returned is roughly proportional to the number of misaligned memory accesses (the size of the problem). |
| | 07H | EMON_KNI_PREF _DISPATCHED | <br>00H<br>01H<br>02H<br>03H | Number of Streaming SIMD extensions prefetch/weakly-ordered instructions dispatched (speculative prefetches are included in counting):<br>0: prefetch NTA<br>1: prefetch T1<br>2: prefetch T2<br>3: weakly ordered stores | Counters 0 and 1. Pentium III processor only. |
| | 4BH | EMON_KNI_PREF _MISS | <br>00H<br>01H<br>02H<br>03H | Number of prefetch/weakly-ordered instructions that miss all caches:<br>0: prefetch NTA<br>1: prefetch T1<br>2: prefetch T2<br>3: weakly ordered stores | Counters 0 and 1. Pentium III processor only. |
| Instruction Decoding and Retirement | C0H | INST_RETIRED | 00H | Number of instructions retired. | A hardware interrupt received during/after the last iteration of the REP STOS flow causes the counter to undercount by 1 instruction. |
| | | | | | An SMI received while executing a HLT instruction will cause the performance counter to not count the RSM instruction and undercount by 1. |

**Table 19-32. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description | Comments |
|---|---|---|---|---|---|
| | C2H | UOPS_RETIRED | 00H | Number of μops retired. | |
| | D0H | INST_DECODED | 00H | Number of instructions decoded. | |
| | D8H | EMON_KNI_INST_RETIRED | 00H<br>01H | Number of Streaming SIMD extensions retired:<br>0: packed & scalar<br>1: scalar | Counters 0 and 1. Pentium III processor only. |
| | D9H | EMON_KNI_COMP_INST_RET | 00H<br>01H | Number of Streaming SIMD extensions computation instructions retired:<br>0: packed and scalar<br>1: scalar | Counters 0 and 1. Pentium III processor only. |
| Interrupts | C8H | HW_INT_RX | 00H | Number of hardware interrupts received. | |
| | C6H | CYCLES_INT_MASKED | 00H | Number of processor cycles for which interrupts are disabled. | |
| | C7H | CYCLES_INT_PENDING_AND_MASKED | 00H | Number of processor cycles for which interrupts are disabled and interrupts are pending. | |
| Branches | C4H | BR_INST_RETIRED | 00H | Number of branch instructions retired. | |
| | C5H | BR_MISS_PRED_RETIRED | 00H | Number of mispredicted branches retired. | |
| | C9H | BR_TAKEN_RETIRED | 00H | Number of taken branches retired. | |
| | CAH | BR_MISS_PRED_TAKEN_RET | 00H | Number of taken mispredictions branches retired. | |
| | E0H | BR_INST_DECODED | 00H | Number of branch instructions decoded. | |
| | E2H | BTB_MISSES | 00H | Number of branches for which the BTB did not produce a prediction. | |
| | E4H | BR_BOGUS | 00H | Number of bogus branches. | |
| | E6H | BACLEARS | 00H | Number of times BACLEAR is asserted.<br>This is the number of times that a static branch prediction was made, in which the branch decoder decided to make a branch prediction because the BTB did not. | |
| Stalls | A2H | RESOURCE_STALLS | 00H | Incremented by 1 during every cycle for which there is a resource related stall.<br>Includes register renaming buffer entries, memory buffer entries. | |

**Table 19-32. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description | Comments |
|---|---|---|---|---|---|
| | | | | Does not include stalls due to bus queue full, too many cache misses, etc.<br>In addition to resource related stalls, this event counts some other events.<br>Includes stalls arising during branch misprediction recovery, such as if retirement of the mispredicted branch is delayed and stalls arising while store buffer is draining from synchronizing operations. | |
| | D2H | PARTIAL_RAT_ STALLS | 00H | Number of cycles or events for partial stalls. This includes flag partial stalls. | |
| Segment Register Loads | 06H | SEGMENT_REG_ LOADS | 00H | Number of segment register loads. | |
| Clocks | 79H | CPU_CLK_ UNHALTED | 00H | Number of cycles during which the processor is not halted. | |
| MMX Unit | B0H | MMX_INSTR_ EXEC | 00H | Number of MMX Instructions Executed. | Available in Intel Celeron, Pentium II and Pentium II Xeon processors only.<br>Does not account for MOVQ and MOVD stores from register to memory. |
| | B1H | MMX_SAT_ INSTR_EXEC | 00H | Number of MMX Saturating Instructions Executed. | Available in Pentium II and Pentium III processors only. |
| | B2H | MMX_UOPS_ EXEC | 0FH | Number of MMX μops Executed. | Available in Pentium II and Pentium III processors only. |
| | B3H | MMX_INSTR_ TYPE_EXEC | 01H<br>02H<br>04H<br>08H<br>10H<br>20H | MMX packed multiply instructions executed.<br>MMX packed shift instructions executed.<br>MMX pack operation instructions executed.<br>MMX unpack operation instructions executed.<br>MMX packed logical instructions executed.<br>MMX packed arithmetic instructions executed. | Available in Pentium II and Pentium III processors only. |
| | CCH | FP_MMX_TRANS | 00H<br>01H | Transitions from MMX instruction to floating-point instructions.<br>Transitions from floating-point instructions to MMX instructions. | Available in Pentium II and Pentium III processors only. |
| | CDH | MMX_ASSIST | 00H | Number of MMX Assists (that is, the number of EMMS instructions executed). | Available in Pentium II and Pentium III processors only. |
| | CEH | MMX_INSTR_RET | 00H | Number of MMX Instructions Retired. | Available in Pentium II processors only. |
| Segment Register Renaming | D4H | SEG_RENAME_ STALLS | | Number of Segment Register Renaming Stalls: | Available in Pentium II and Pentium III processors only. |

**Table 19-32. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

| Unit | Event Num. | Mnemonic Event Name | Unit Mask | Description | Comments |
|---|---|---|---|---|---|
| | | | 02H | Segment register ES | |
| | | | 04H | Segment register DS | |
| | | | 08H | Segment register FS | |
| | | | 0FH | Segment register FS | |
| | | | | Segment registers ES + DS + FS + GS | |
| | D5H | SEG_REG_ RENAMES | | Number of Segment Register Renames: | Available in Pentium II and Pentium III processors only. |
| | | | 01H | Segment register ES | |
| | | | 02H | Segment register DS | |
| | | | 04H | Segment register FS | |
| | | | 08H | Segment register FS | |
| | | | 0FH | Segment registers ES + DS + FS + GS | |
| | D6H | RET_SEG_ RENAMES | 00H | Number of segment register rename events retired. | Available in Pentium II and Pentium III processors only. |

**NOTES:**

1. Several L2 cache events, where noted, can be further qualified using the Unit Mask (UMSK) field in the PerfEvtSel0 and PerfEvtSel1 registers. The lower 4 bits of the Unit Mask field are used in conjunction with L2 events to indicate the cache state or cache states involved.

   The P6 family processors identify cache states using the "MESI" protocol and consequently each bit in the Unit Mask field represents one of the four states: UMSK[3] = M (8H) state, UMSK[2] = E (4H) state, UMSK[1] = S (2H) state, and UMSK[0] = I (1H) state. UMSK[3:0] = MESI" (FH) should be used to collect data for all states; UMSK = 0H, for the applicable events, will result in nothing being counted.

2. All of the external bus logic (EBL) events, except where noted, can be further qualified using the Unit Mask (UMSK) field in the PerfEvtSel0 and PerfEvtSel1 registers.

   Bit 5 of the UMSK field is used in conjunction with the EBL events to indicate whether the processor should count transactions that are self- generated (UMSK[5] = 0) or transactions that result from any processor on the bus (UMSK[5] = 1).

3. L2 cache locks, so it is possible to have a zero count.

## 19.16 PENTIUM PROCESSOR PERFORMANCE-MONITORING EVENTS

Table 19-33 lists the events that can be counted with the performance-monitoring counters for the Pentium processor. The Event Number column gives the hexadecimal code that identifies the event and that is entered in the ES0 or ES1 (event select) fields of the CESR MSR. The Mnemonic Event Name column gives the name of the event, and the Description and Comments columns give detailed descriptions of the events. Most events can be counted with either counter 0 or counter 1; however, some events can only be counted with only counter 0 or only counter 1 (as noted).

**NOTE**

The events in the table that are shaded are implemented only in the Pentium processor with MMX technology.

### Table 19-33. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters

| Event Num. | Mnemonic Event Name | Description | Comments |
|---|---|---|---|
| 00H | DATA_READ | Number of memory data reads (internal data cache hit and miss combined). | Split cycle reads are counted individually. Data Memory Reads that are part of TLB miss processing are not included. These events may occur at a maximum of two per clock. I/O is not included. |
| 01H | DATA_WRITE | Number of memory data writes (internal data cache hit and miss combined); I/O not included. | Split cycle writes are counted individually. These events may occur at a maximum of two per clock. I/O is not included. |
| 0H2 | DATA_TLB_MISS | Number of misses to the data cache translation look-aside buffer. | |
| 03H | DATA_READ_MISS | Number of memory read accesses that miss the internal data cache whether or not the access is cacheable or noncacheable. | Additional reads to the same cache line after the first BRDY# of the burst line fill is returned but before the final (fourth) BRDY# has been returned, will not cause the counter to be incremented additional times.<br>Data accesses that are part of TLB miss processing are not included. Accesses directed to I/O space are not included. |
| 04H | DATA WRITE MISS | Number of memory write accesses that miss the internal data cache whether or not the access is cacheable or noncacheable. | Data accesses that are part of TLB miss processing are not included. Accesses directed to I/O space are not included. |
| 05H | WRITE_HIT_TO_ M-_OR_E-STATE_LINES | Number of write hits to exclusive or modified lines in the data cache. | These are the writes that may be held up if EWBE# is inactive. These events may occur a maximum of two per clock. |
| 06H | DATA_CACHE_ LINES_ WRITTEN_BACK | Number of dirty lines (all) that are written back, regardless of the cause. | Replacements and internal and external snoops can all cause writeback and are counted. |
| 07H | EXTERNAL_ SNOOPS | Number of accepted external snoops whether they hit in the code cache or data cache or neither. | Assertions of EADS# outside of the sampling interval are not counted, and no internal snoops are counted. |
| 08H | EXTERNAL_DATA_ CACHE_SNOOP_ HITS | Number of external snoops to the data cache. | Snoop hits to a valid line in either the data cache, the data line fill buffer, or one of the write back buffers are all counted as hits. |
| 09H | MEMORY ACCESSES IN BOTH PIPES | Number of data memory reads or writes that are paired in both pipes of the pipeline. | These accesses are not necessarily run in parallel due to cache misses, bank conflicts, etc. |
| 0AH | BANK CONFLICTS | Number of actual bank conflicts. | |
| 0BH | MISALIGNED DATA MEMORY OR I/O REFERENCES | Number of memory or I/O reads or writes that are misaligned. | A 2- or 4-byte access is misaligned when it crosses a 4-byte boundary; an 8-byte access is misaligned when it crosses an 8-byte boundary. Ten byte accesses are treated as two separate accesses of 8 and 2 bytes each. |
| 0CH | CODE READ | Number of instruction reads; whether the read is cacheable or noncacheable. | Individual 8-byte noncacheable instruction reads are counted. |
| 0DH | CODE TLB MISS | Number of instruction reads that miss the code TLB whether the read is cacheable or noncacheable. | Individual 8-byte noncacheable instruction reads are counted. |
| 0EH | CODE CACHE MISS | Number of instruction reads that miss the internal code cache; whether the read is cacheable or noncacheable. | Individual 8-byte noncacheable instruction reads are counted. |

**Table 19-33. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name | Description | Comments |
|---|---|---|---|
| 0FH | ANY SEGMENT REGISTER LOADED | Number of writes into any segment register in real or protected mode including the LDTR, GDTR, IDTR, and TR. | Segment loads are caused by explicit segment register load instructions, far control transfers, and task switches. Far control transfers and task switches causing a privilege level change will signal this event twice. Interrupts and exceptions may initiate a far control transfer. |
| 10H | Reserved | | |
| 11H | Reserved | | |
| 12H | Branches | Number of taken and not taken branches, including: conditional branches, jumps, calls, returns, software interrupts, and interrupt returns. | Also counted as taken branches are serializing instructions, VERR and VERW instructions, some segment descriptor loads, hardware interrupts (including FLUSH#), and programmatic exceptions that invoke a trap or fault handler. The pipe is not necessarily flushed.<br>The number of branches actually executed is measured, not the number of predicted branches. |
| 13H | BTB_HITS | Number of BTB hits that occur. | Hits are counted only for those instructions that are actually executed. |
| 14H | TAKEN_BRANCH_ OR_BTB_HIT | Number of taken branches or BTB hits that occur. | This event type is a logical OR of taken branches and BTB hits. It represents an event that may cause a hit in the BTB. Specifically, it is either a candidate for a space in the BTB or it is already in the BTB. |
| 15H | PIPELINE FLUSHES | Number of pipeline flushes that occur<br>Pipeline flushes are caused by BTB misses on taken branches, mispredictions, exceptions, interrupts, and some segment descriptor loads. | The counter will not be incremented for serializing instructions (serializing instructions cause the prefetch queue to be flushed but will not trigger the Pipeline Flushed event counter) and software interrupts (software interrupts do not flush the pipeline). |
| 16H | INSTRUCTIONS_ EXECUTED | Number of instructions executed (up to two per clock). | Invocations of a fault handler are considered instructions. All hardware and software interrupts and exceptions will also cause the count to be incremented. Repeat prefixed string instructions will only increment this counter once despite the fact that the repeat loop executes the same instruction multiple times until the loop criteria is satisfied.<br>This applies to all the Repeat string instruction prefixes (i.e., REP, REPE, REPZ, REPNE, and REPNZ). This counter will also only increment once per each HLT instruction executed regardless of how many cycles the processor remains in the HALT state. |
| 17H | INSTRUCTIONS_ EXECUTED_ V PIPE | Number of instructions executed in the V_pipe.<br>The event indicates the number of instructions that were paired. | This event is the same as the 16H event except it only counts the number of instructions actually executed in the V-pipe. |
| 18H | BUS_CYCLE_ DURATION | Number of clocks while a bus cycle is in progress.<br>This event measures bus use. | The count includes HLDA, AHOLD, and BOFF# clocks. |
| 19H | WRITE_BUFFER_ FULL_STALL_ DURATION | Number of clocks while the pipeline is stalled due to full write buffers. | Full write buffers stall data memory read misses, data memory write misses, and data memory write hits to S-state lines. Stalls on I/O accesses are not included. |

**Table 19-33. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name | Description | Comments |
|---|---|---|---|
| 1AH | WAITING_FOR_ DATA_MEMORY_ READ_STALL_ DURATION | Number of clocks while the pipeline is stalled while waiting for data memory reads. | Data TLB Miss processing is also included in the count. The pipeline stalls while a data memory read is in progress including attempts to read that are not bypassed while a line is being filled. |
| 1BH | STALL ON WRITE TO AN E- OR M-STATE LINE | Number of stalls on writes to E- or M-state lines. | |
| 1CH | LOCKED BUS CYCLE | Number of locked bus cycles that occur as the result of the LOCK prefix or LOCK instruction, page-table updates, and descriptor table updates. | Only the read portion of the locked read-modify-write is counted. Split locked cycles (SCYC active) count as two separate accesses. Cycles restarted due to BOFF# are not re-counted. |
| 1DH | I/O READ OR WRITE CYCLE | Number of bus cycles directed to I/O space. | Misaligned I/O accesses will generate two bus cycles. Bus cycles restarted due to BOFF# are not re-counted. |
| 1EH | NONCACHEABLE_ MEMORY_READS | Number of noncacheable instruction or data memory read bus cycles.<br>The count includes read cycles caused by TLB misses, but does not include read cycles to I/O space. | Cycles restarted due to BOFF# are not re-counted. |
| 1FH | PIPELINE_AGI_ STALLS | Number of address generation interlock (AGI) stalls.<br>An AGI occurring in both the U- and V-pipelines in the same clock signals this event twice. | An AGI occurs when the instruction in the execute stage of either of U- or V-pipelines is writing to either the index or base address register of an instruction in the D2 (address generation) stage of either the U- or V- pipelines. |
| 20H | Reserved | | |
| 21H | Reserved | | |
| 22H | FLOPS | Number of floating-point operations that occur. | Number of floating-point adds, subtracts, multiplies, divides, remainders, and square roots are counted. The transcendental instructions consist of multiple adds and multiplies and will signal this event multiple times. Instructions generating the divide-by-zero, negative square root, special operand, or stack exceptions will not be counted.<br>Instructions generating all other floating-point exceptions will be counted. The integer multiply instructions and other instructions which use the x87 FPU will be counted. |
| 23H | BREAKPOINT MATCH ON DR0 REGISTER | Number of matches on register DR0 breakpoint. | The counters is incremented regardless if the breakpoints are enabled or not. However, if breakpoints are not enabled, code breakpoint matches will not be checked for instructions executed in the V-pipe and will not cause this counter to be incremented. (They are checked on instruction executed in the U-pipe only when breakpoints are not enabled.)<br>These events correspond to the signals driven on the BP[3:0] pins. Refer to Chapter 17, "Debug, Branch Profile, TSC, and Resource Monitoring Features" for more information. |
| 24H | BREAKPOINT MATCH ON DR1 REGISTER | Number of matches on register DR1 breakpoint. | See comment for 23H event. |

### Table 19-33. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)

| Event Num. | Mnemonic Event Name | Description | Comments |
|---|---|---|---|
| 25H | BREAKPOINT MATCH ON DR2 REGISTER | Number of matches on register DR2 breakpoint. | See comment for 23H event. |
| 26H | BREAKPOINT MATCH ON DR3 REGISTER | Number of matches on register DR3 breakpoint. | See comment for 23H event. |
| 27H | HARDWARE INTERRUPTS | Number of taken INTR and NMI interrupts. | |
| 28H | DATA_READ_OR_ WRITE | Number of memory data reads and/or writes (internal data cache hit and miss combined). | Split cycle reads and writes are counted individually. Data Memory Reads that are part of TLB miss processing are not included. These events may occur at a maximum of two per clock. I/O is not included. |
| 29H | DATA_READ_MISS OR_WRITE MISS | Number of memory read and/or write accesses that miss the internal data cache, whether or not the access is cacheable or noncacheable. | Additional reads to the same cache line after the first BRDY# of the burst line fill is returned but before the final (fourth) BRDY# has been returned, will not cause the counter to be incremented additional times.<br>Data accesses that are part of TLB miss processing are not included. Accesses directed to I/O space are not included. |
| 2AH | BUS_OWNERSHIP_ LATENCY (Counter 0) | The time from LRM bus ownership request to bus ownership granted (that is, the time from the earlier of a PBREQ (0), PHITM# or HITM# assertion to a PBGNT assertion) | The ratio of the 2AH events counted on counter 0 and counter 1 is the average stall time due to bus ownership conflict. |
| 2AH | BUS OWNERSHIP TRANSFERS (Counter 1) | The number of buss ownership transfers (that is, the number of PBREQ (0) assertions | The ratio of the 2AH events counted on counter 0 and counter 1 is the average stall time due to bus ownership conflict. |
| 2BH | MMX_ INSTRUCTIONS_ EXECUTED_ U-PIPE (Counter 0) | Number of MMX instructions executed in the U-pipe | |
| 2BH | MMX_ INSTRUCTIONS_ EXECUTED_ V-PIPE (Counter 1) | Number of MMX instructions executed in the V-pipe | |
| 2CH | CACHE_M-STATE_LINE_ SHARING (Counter 0) | Number of times a processor identified a hit to a modified line due to a memory access in the other processor (PHITM (O)) | If the average memory latencies of the system are known, this event enables the user to count the Write Backs on PHITM(O) penalty and the Latency on Hit Modified(I) penalty. |
| 2CH | CACHE_LINE_ SHARING (Counter 1) | Number of shared data lines in the L1 cache (PHIT (O)) | |
| 2DH | EMMS_ INSTRUCTIONS_ EXECUTED (Counter 0) | Number of EMMS instructions executed | |

**Table 19-33. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name | Description | Comments |
|---|---|---|---|
| 2DH | TRANSITIONS_ BETWEEN_MMX_ AND_FP_ INSTRUCTIONS (Counter 1) | Number of transitions between MMX and floating-point instructions or vice versa<br>An even count indicates the processor is in MMX state. an odd count indicates it is in FP state. | This event counts the first floating-point instruction following an MMX instruction or first MMX instruction following a floating-point instruction.<br>The count may be used to estimate the penalty in transitions between floating-point state and MMX state. |
| 2EH | BUS_UTILIZATION_ DUE_TO_ PROCESSOR_ ACTIVITY (Counter 0) | Number of clocks the bus is busy due to the processor's own activity (the bus activity that is caused by the processor) | |
| 2EH | WRITES_TO_ NONCACHEABLE_ MEMORY (Counter 1) | Number of write accesses to noncacheable memory | The count includes write cycles caused by TLB misses and I/O write cycles.<br>Cycles restarted due to BOFF# are not re-counted. |
| 2FH | SATURATING_ MMX_ INSTRUCTIONS_ EXECUTED (Counter 0) | Number of saturating MMX instructions executed, independently of whether they actually saturated. | |
| 2FH | SATURATIONS_ PERFORMED (Counter 1) | Number of MMX instructions that used saturating arithmetic when at least one of its results actually saturated | If an MMX instruction operating on 4 doublewords saturated in three out of the four results, the counter will be incremented by one only. |
| 30H | NUMBER_OF_ CYCLES_NOT_IN_ HALT_STATE (Counter 0) | Number of cycles the processor is not idle due to HLT instruction | This event will enable the user to calculate "net CPI". Note that during the time that the processor is executing the HLT instruction, the Time-Stamp Counter is not disabled. Since this event is controlled by the Counter Controls CC0, CC1 it can be used to calculate the CPI at CPL=3, which the TSC cannot provide. |
| 30H | DATA_CACHE_ TLB_MISS_ STALL_DURATION (Counter 1) | Number of clocks the pipeline is stalled due to a data cache translation look-aside buffer (TLB) miss | |
| 31H | MMX_ INSTRUCTION_ DATA_READS (Counter 0) | Number of MMX instruction data reads | |
| 31H | MMX_ INSTRUCTION_ DATA_READ_ MISSES (Counter 1) | Number of MMX instruction data read misses | |
| 32H | FLOATING_POINT_S TALLS_DURATION (Counter 0) | Number of clocks while pipe is stalled due to a floating-point freeze | |
| 32H | TAKEN_BRANCHES (Counter 1) | Number of taken branches | |

**Table 19-33. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name | Description | Comments |
|---|---|---|---|
| 33H | D1_STARVATION_ AND_FIFO_IS_ EMPTY (Counter 0) | Number of times D1 stage cannot issue ANY instructions since the FIFO buffer is empty | The D1 stage can issue 0, 1, or 2 instructions per clock if those are available in an instructions FIFO buffer. |
| 33H | D1_STARVATION_ AND_ONLY_ONE_ INSTRUCTION_IN_ FIFO (Counter 1) | Number of times the D1 stage issues a single instruction (since the FIFO buffer had just one instruction ready) | The D1 stage can issue 0, 1, or 2 instructions per clock if those are available in an instructions FIFO buffer.<br>When combined with the previously defined events, Instruction Executed (16H) and Instruction Executed in the V-pipe (17H), this event enables the user to calculate the numbers of time pairing rules prevented issuing of two instructions. |
| 34H | MMX_ INSTRUCTION_ DATA_WRITES (Counter 0) | Number of data writes caused by MMX instructions | |
| 34H | MMX_ INSTRUCTION_ DATA_WRITE_ MISSES (Counter 1) | Number of data write misses caused by MMX instructions | |
| 35H | PIPELINE_ FLUSHES_DUE_ TO_WRONG_ BRANCH_ PREDICTIONS (Counter 0) | Number of pipeline flushes due to wrong branch predictions resolved in either the E-stage or the WB-stage | The count includes any pipeline flush due to a branch that the pipeline did not follow correctly. It includes cases where a branch was not in the BTB, cases where a branch was in the BTB but was mispredicted, and cases where a branch was correctly predicted but to the wrong address.<br>Branches are resolved in either the Execute stage (E-stage) or the Writeback stage (WB-stage). In the later case, the misprediction penalty is larger by one clock. The difference between the 35H event count in counter 0 and counter 1 is the number of E-stage resolved branches. |
| 35H | PIPELINE_ FLUSHES_DUE_ TO_WRONG_ BRANCH_ PREDICTIONS_ RESOLVED_IN_ WB-STAGE (Counter 1) | Number of pipeline flushes due to wrong branch predictions resolved in the WB-stage | See note for event 35H (Counter 0). |
| 36H | MISALIGNED_ DATA_MEMORY_ REFERENCE_ON_ MMX_ INSTRUCTIONS (Counter 0) | Number of misaligned data memory references when executing MMX instructions | |
| 36H | PIPELINE_ ISTALL_FOR_MMX_ INSTRUCTION_ DATA_MEMORY_ READS (Counter 1) | Number clocks during pipeline stalls caused by waits form MMX instruction data memory reads | T3: |

**Table 19-33. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

| Event Num. | Mnemonic Event Name | Description | Comments |
|---|---|---|---|
| 37H | MISPREDICTED_ OR_ UNPREDICTED_ RETURNS (Counter 1) | Number of returns predicted incorrectly or not predicted at all | The count is the difference between the total number of executed returns and the number of returns that were correctly predicted. Only RET instructions are counted (for example, IRET instructions are not counted). |
| 37H | PREDICTED_ RETURNS (Counter 1) | Number of predicted returns (whether they are predicted correctly and incorrectly | Only RET instructions are counted (for example, IRET instructions are not counted). |
| 38H | MMX_MULTIPLY_ UNIT_INTERLOCK (Counter 0) | Number of clocks the pipe is stalled since the destination of previous MMX multiply instruction is not ready yet | The counter will not be incremented if there is another cause for a stall. For each occurrence of a multiply interlock, this event will be counted twice (if the stalled instruction comes on the next clock after the multiply) or by once (if the stalled instruction comes two clocks after the multiply). |
| 38H | MOVD/MOVQ_ STORE_STALL_ DUE_TO_ PREVIOUS_MMX_ OPERATION (Counter 1) | Number of clocks a MOVD/MOVQ instruction store is stalled in D2 stage due to a previous MMX operation with a destination to be used in the store instruction. | |
| 39H | RETURNS (Counter 0) | Number or returns executed. | Only RET instructions are counted; IRET instructions are not counted. Any exception taken on a RET instruction and any interrupt recognized by the processor on the instruction boundary prior to the execution of the RET instruction will also cause this counter to be incremented. |
| 39H | Reserved | | |
| 3AH | BTB_FALSE_ ENTRIES (Counter 0) | Number of false entries in the Branch Target Buffer | False entries are causes for misprediction other than a wrong prediction. |
| 3AH | BTB_MISS_ PREDICTION_ON_ NOT-TAKEN_ BRANCH (Counter 1) | Number of times the BTB predicted a not-taken branch as taken | |
| 3BH | FULL_WRITE_ BUFFER_STALL_ DURATION_ WHILE_ EXECUTING_MMX_I NSTRUCTIONS (Counter 0) | Number of clocks while the pipeline is stalled due to full write buffers while executing MMX instructions | |
| 3BH | STALL_ON_MMX_ INSTRUCTION_ WRITE_TO E-_OR_ M-STATE_LINE (Counter 1) | Number of clocks during stalls on MMX instructions writing to E- or M-state lines | |

# CHAPTER 20
# 8086 EMULATION

IA-32 processors (beginning with the Intel386 processor) provide two ways to execute new or legacy programs that are assembled and/or compiled to run on an Intel 8086 processor:

- Real-address mode.
- Virtual-8086 mode.

Figure 2-3 shows the relationship of these operating modes to protected mode and system management mode (SMM).

When the processor is powered up or reset, it is placed in the real-address mode. This operating mode almost exactly duplicates the execution environment of the Intel 8086 processor, with some extensions. Virtually any program assembled and/or compiled to run on an Intel 8086 processor will run on an IA-32 processor in this mode.

When running in protected mode, the processor can be switched to virtual-8086 mode to run 8086 programs. This mode also duplicates the execution environment of the Intel 8086 processor, with extensions. In virtual-8086 mode, an 8086 program runs as a separate protected-mode task. Legacy 8086 programs are thus able to run under an operating system (such as Microsoft Windows*) that takes advantage of protected mode and to use protected-mode facilities, such as the protected-mode interrupt- and exception-handling facilities. Protected-mode multitasking permits multiple virtual-8086 mode tasks (with each task running a separate 8086 program) to be run on the processor along with other non-virtual-8086 mode tasks.

This section describes both the basic real-address mode execution environment and the virtual-8086-mode execution environment, available on the IA-32 processors beginning with the Intel386 processor.

## 20.1 REAL-ADDRESS MODE

The IA-32 architecture's real-address mode runs programs written for the Intel 8086, Intel 8088, Intel 80186, and Intel 80188 processors, or for the real-address mode of the Intel 286, Intel386, Intel486, Pentium, P6 family, Pentium 4, and Intel Xeon processors.

The execution environment of the processor in real-address mode is designed to duplicate the execution environment of the Intel 8086 processor. To an 8086 program, a processor operating in real-address mode behaves like a high-speed 8086 processor. The principal features of this architecture are defined in Chapter 3, "Basic Execution Environment", of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*.

The following is a summary of the core features of the real-address mode execution environment as would be seen by a program written for the 8086:

- The processor supports a nominal 1-MByte physical address space (see Section 20.1.1, "Address Translation in Real-Address Mode", for specific details). This address space is divided into segments, each of which can be up to 64 KBytes in length. The base of a segment is specified with a 16-bit segment selector, which is zero extended to form a 20-bit offset from address 0 in the address space. An operand within a segment is addressed with a 16-bit offset from the base of the segment. A physical address is thus formed by adding the offset to the 20-bit segment base (see Section 20.1.1, "Address Translation in Real-Address Mode").
- All operands in "native 8086 code" are 8-bit or 16-bit values. (Operand size override prefixes can be used to access 32-bit operands.)
- Eight 16-bit general-purpose registers are provided: AX, BX, CX, DX, SP, BP, SI, and DI. The extended 32 bit registers (EAX, EBX, ECX, EDX, ESP, EBP, ESI, and EDI) are accessible to programs that explicitly perform a size override operation.
- Four segment registers are provided: CS, DS, SS, and ES. (The FS and GS registers are accessible to programs that explicitly access them.) The CS register contains the segment selector for the code segment; the DS and ES registers contain segment selectors for data segments; and the SS register contains the segment selector for the stack segment.
- The 8086 16-bit instruction pointer (IP) is mapped to the lower 16-bits of the EIP register. Note this register is a 32-bit register and unintentional address wrapping may occur.

- The 16-bit FLAGS register contains status and control flags. (This register is mapped to the 16 least significant bits of the 32-bit EFLAGS register.)
- All of the Intel 8086 instructions are supported (see Section 20.1.3, "Instructions Supported in Real-Address Mode").
- A single, 16-bit-wide stack is provided for handling procedure calls and invocations of interrupt and exception handlers. This stack is contained in the stack segment identified with the SS register. The SP (stack pointer) register contains an offset into the stack segment. The stack grows down (toward lower segment offsets) from the stack pointer. The BP (base pointer) register also contains an offset into the stack segment that can be used as a pointer to a parameter list. When a CALL instruction is executed, the processor pushes the current instruction pointer (the 16 least-significant bits of the EIP register and, on far calls, the current value of the CS register) onto the stack. On a return, initiated with a RET instruction, the processor pops the saved instruction pointer from the stack into the EIP register (and CS register on far returns). When an implicit call to an interrupt or exception handler is executed, the processor pushes the EIP, CS, and EFLAGS (low-order 16-bits only) registers onto the stack. On a return from an interrupt or exception handler, initiated with an IRET instruction, the processor pops the saved instruction pointer and EFLAGS image from the stack into the EIP, CS, and EFLAGS registers.
- A single interrupt table, called the "interrupt vector table" or "interrupt table," is provided for handling interrupts and exceptions (see Figure 20-2). The interrupt table (which has 4-byte entries) takes the place of the interrupt descriptor table (IDT, with 8-byte entries) used when handling protected-mode interrupts and exceptions. Interrupt and exception vector numbers provide an index to entries in the interrupt table. Each entry provides a pointer (called a "vector") to an interrupt- or exception-handling procedure. See Section 20.1.4, "Interrupt and Exception Handling", for more details. It is possible for software to relocate the IDT by means of the LIDT instruction on IA-32 processors beginning with the Intel386 processor.
- The x87 FPU is active and available to execute x87 FPU instructions in real-address mode. Programs written to run on the Intel 8087 and Intel 287 math coprocessors can be run in real-address mode without modification.

The following extensions to the Intel 8086 execution environment are available in the IA-32 architecture's real-address mode. If backwards compatibility to Intel 286 and Intel 8086 processors is required, these features should not be used in new programs written to run in real-address mode.

- Two additional segment registers (FS and GS) are available.
- Many of the integer and system instructions that have been added to later IA-32 processors can be executed in real-address mode (see Section 20.1.3, "Instructions Supported in Real-Address Mode").
- The 32-bit operand prefix can be used in real-address mode programs to execute the 32-bit forms of instructions. This prefix also allows real-address mode programs to use the processor's 32-bit general-purpose registers.
- The 32-bit address prefix can be used in real-address mode programs, allowing 32-bit offsets.

The following sections describe address formation, registers, available instructions, and interrupt and exception handling in real-address mode. For information on I/O in real-address mode, see Chapter 16, "Input/Output", of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*.

### 20.1.1 Address Translation in Real-Address Mode

In real-address mode, the processor does not interpret segment selectors as indexes into a descriptor table; instead, it uses them directly to form linear addresses as the 8086 processor does. It shifts the segment selector left by 4 bits to form a 20-bit base address (see Figure 20-1). The offset into a segment is added to the base address to create a linear address that maps directly to the physical address space.

When using 8086-style address translation, it is possible to specify addresses larger than 1 MByte. For example, with a segment selector value of FFFFH and an offset of FFFFH, the linear (and physical) address would be 10FFEFH (1 megabyte plus 64 KBytes). The 8086 processor, which can form addresses only up to 20 bits long, truncates the high-order bit, thereby "wrapping" this address to FFEFH. When operating in real-address mode, however, the processor does not truncate such an address and uses it as a physical address. (Note, however, that for IA-32 processors beginning with the Intel486 processor, the A20M# signal can be used in real-address mode to mask address line A20, thereby mimicking the 20-bit wrap-around behavior of the 8086 processor.) Care should be take to ensure that A20M# based address wrapping is handled correctly in multiprocessor based system.

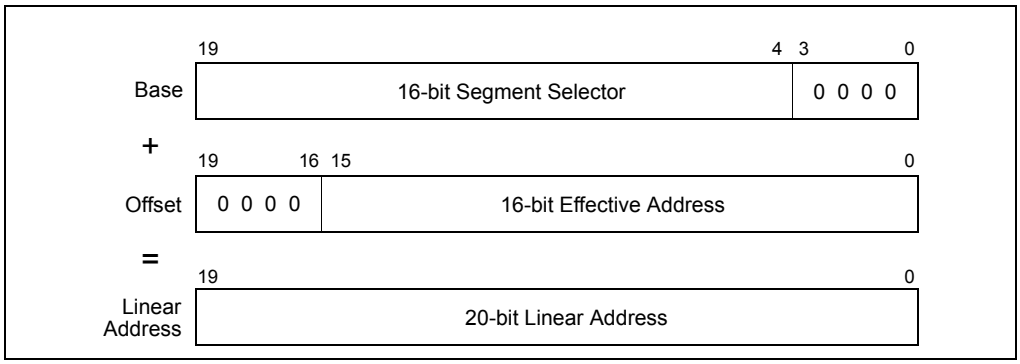

**Figure 20-1. Real-Address Mode Address Translation**

The IA-32 processors beginning with the Intel386 processor can generate 32-bit offsets using an address override prefix; however, in real-address mode, the value of a 32-bit offset may not exceed FFFFH without causing an exception.

For full compatibility with Intel 286 real-address mode, pseudo-protection faults (interrupt 12 or 13) occur if a 32-bit offset is generated outside the range 0 through FFFFH.

## 20.1.2 Registers Supported in Real-Address Mode

The register set available in real-address mode includes all the registers defined for the 8086 processor plus the new registers introduced in later IA-32 processors, such as the FS and GS segment registers, the debug registers, the control registers, and the floating-point unit registers. The 32-bit operand prefix allows a real-address mode program to use the 32-bit general-purpose registers (EAX, EBX, ECX, EDX, ESP, EBP, ESI, and EDI).

## 20.1.3 Instructions Supported in Real-Address Mode

The following instructions make up the core instruction set for the 8086 processor. If backwards compatibility to the Intel 286 and Intel 8086 processors is required, only these instructions should be used in a new program written to run in real-address mode.

- Move (MOV) instructions that move operands between general-purpose registers, segment registers, and between memory and general-purpose registers.
- The exchange (XCHG) instruction.
- Load segment register instructions LDS and LES.
- Arithmetic instructions ADD, ADC, SUB, SBB, MUL, IMUL, DIV, IDIV, INC, DEC, CMP, and NEG.
- Logical instructions AND, OR, XOR, and NOT.
- Decimal instructions DAA, DAS, AAA, AAS, AAM, and AAD.
- Stack instructions PUSH and POP (to general-purpose registers and segment registers).
- Type conversion instructions CWD, CDQ, CBW, and CWDE.
- Shift and rotate instructions SAL, SHL, SHR, SAR, ROL, ROR, RCL, and RCR.
- TEST instruction.
- Control instructions JMP, J*cc*, CALL, RET, LOOP, LOOPE, and LOOPNE.
- Interrupt instructions INT *n*, INTO, and IRET.
- EFLAGS control instructions STC, CLC, CMC, CLD, STD, LAHF, SAHF, PUSHF, and POPF.
- I/O instructions IN, INS, OUT, and OUTS.
- Load effective address (LEA) instruction, and translate (XLATB) instruction.

- LOCK prefix.
- Repeat prefixes REP, REPE, REPZ, REPNE, and REPNZ.
- Processor halt (HLT) instruction.
- No operation (NOP) instruction.

The following instructions, added to later IA-32 processors (some in the Intel 286 processor and the remainder in the Intel386 processor), can be executed in real-address mode, if backwards compatibility to the Intel 8086 processor is not required.

- Move (MOV) instructions that operate on the control and debug registers.
- Load segment register instructions LSS, LFS, and LGS.
- Generalized multiply instructions and multiply immediate data.
- Shift and rotate by immediate counts.
- Stack instructions PUSHA, PUSHAD, POPA and POPAD, and PUSH immediate data.
- Move with sign extension instructions MOVSX and MOVZX.
- Long-displacement J*cc* instructions.
- Exchange instructions CMPXCHG, CMPXCHG8B, and XADD.
- String instructions MOVS, CMPS, SCAS, LODS, and STOS.
- Bit test and bit scan instructions BT, BTS, BTR, BTC, BSF, and BSR; the byte-set-on condition instruction SET*cc*; and the byte swap (BSWAP) instruction.
- Double shift instructions SHLD and SHRD.
- EFLAGS control instructions PUSHF and POPF.
- ENTER and LEAVE control instructions.
- BOUND instruction.
- CPU identification (CPUID) instruction.
- System instructions CLTS, INVD, WINVD, INVLPG, LGDT, SGDT, LIDT, SIDT, LMSW, SMSW, RDMSR, WRMSR, RDTSC, and RDPMC.

Execution of any of the other IA-32 architecture instructions (not given in the previous two lists) in real-address mode result in an invalid-opcode exception (#UD) being generated.

### 20.1.4 Interrupt and Exception Handling

When operating in real-address mode, software must provide interrupt and exception-handling facilities that are separate from those provided in protected mode. Even during the early stages of processor initialization when the processor is still in real-address mode, elementary real-address mode interrupt and exception-handling facilities must be provided to insure reliable operation of the processor, or the initialization code must insure that no interrupts or exceptions will occur.

The IA-32 processors handle interrupts and exceptions in real-address mode similar to the way they handle them in protected mode. When a processor receives an interrupt or generates an exception, it uses the vector number of the interrupt or exception as an index into the interrupt table. (In protected mode, the interrupt table is called the **interrupt descriptor table (IDT)**, but in real-address mode, the table is usually called the **interrupt vector table**, or simply the **interrupt table**.) The entry in the interrupt vector table provides a pointer to an interrupt- or exception-handler procedure. (The pointer consists of a segment selector for a code segment and a 16-bit offset into the segment.) The processor performs the following actions to make an implicit call to the selected handler:

1. Pushes the current values of the CS and EIP registers onto the stack. (Only the 16 least-significant bits of the EIP register are pushed.)
2. Pushes the low-order 16 bits of the EFLAGS register onto the stack.
3. Clears the IF flag in the EFLAGS register to disable interrupts.
4. Clears the TF, RC, and AC flags, in the EFLAGS register.

5. Transfers program control to the location specified in the interrupt vector table.

An IRET instruction at the end of the handler procedure reverses these steps to return program control to the interrupted program. Exceptions do not return error codes in real-address mode.

The interrupt vector table is an array of 4-byte entries (see Figure 20-2). Each entry consists of a far pointer to a handler procedure, made up of a segment selector and an offset. The processor scales the interrupt or exception vector by 4 to obtain an offset into the interrupt table. Following reset, the base of the interrupt vector table is located at physical address 0 and its limit is set to 3FFH. In the Intel 8086 processor, the base address and limit of the interrupt vector table cannot be changed. In the later IA-32 processors, the base address and limit of the interrupt vector table are contained in the IDTR register and can be changed using the LIDT instruction.

(For backward compatibility to Intel 8086 processors, the default base address and limit of the interrupt vector table should not be changed.)

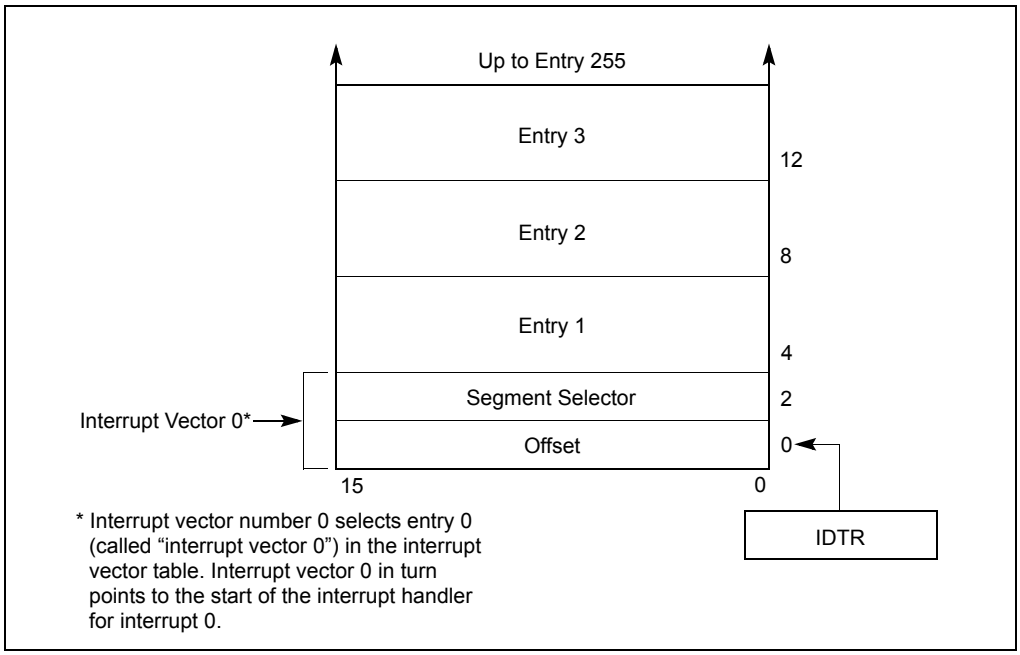

**Figure 20-2. Interrupt Vector Table in Real-Address Mode**

Table 20-1 shows the interrupt and exception vectors that can be generated in real-address mode and virtual-8086 mode, and in the Intel 8086 processor. See Chapter 6, “Interrupt and Exception Handling”, for a description of the exception conditions.

## 20.2 VIRTUAL-8086 MODE

Virtual-8086 mode is actually a special type of a task that runs in protected mode. When the operating-system or executive switches to a virtual-8086-mode task, the processor emulates an Intel 8086 processor. The execution environment of the processor while in the 8086-emulation state is the same as is described in Section 20.1, “Real-Address Mode” for real-address mode, including the extensions. The major difference between the two modes is that in virtual-8086 mode the 8086 emulator uses some protected-mode services (such as the protected-mode interrupt and exception-handling and paging facilities).

As in real-address mode, any new or legacy program that has been assembled and/or compiled to run on an Intel 8086 processor will run in a virtual-8086-mode task. And several 8086 programs can be run as virtual-8086-mode tasks concurrently with normal protected-mode tasks, using the processor's multitasking facilities.

**Table 20-1. Real-Address Mode Exceptions and Interrupts**

| Vector No. | Description | Real-Address Mode | Virtual-8086 Mode | Intel 8086 Processor |
|---|---|---|---|---|
| 0 | Divide Error (#DE) | Yes | Yes | Yes |
| 1 | Debug Exception (#DB) | Yes | Yes | No |
| 2 | NMI Interrupt | Yes | Yes | Yes |
| 3 | Breakpoint (#BP) | Yes | Yes | Yes |
| 4 | Overflow (#OF) | Yes | Yes | Yes |
| 5 | BOUND Range Exceeded (#BR) | Yes | Yes | Reserved |
| 6 | Invalid Opcode (#UD) | Yes | Yes | Reserved |
| 7 | Device Not Available (#NM) | Yes | Yes | Reserved |
| 8 | Double Fault (#DF) | Yes | Yes | Reserved |
| 9 | (Intel reserved. Do not use.) | Reserved | Reserved | Reserved |
| 10 | Invalid TSS (#TS) | Reserved | Yes | Reserved |
| 11 | Segment Not Present (#NP) | Reserved | Yes | Reserved |
| 12 | Stack Fault (#SS) | Yes | Yes | Reserved |
| 13 | General Protection (#GP)* | Yes | Yes | Reserved |
| 14 | Page Fault (#PF) | Reserved | Yes | Reserved |
| 15 | (Intel reserved. Do not use.) | Reserved | Reserved | Reserved |
| 16 | Floating-Point Error (#MF) | Yes | Yes | Reserved |
| 17 | Alignment Check (#AC) | Reserved | Yes | Reserved |
| 18 | Machine Check (#MC) | Yes | Yes | Reserved |
| 19-31 | (Intel reserved. Do not use.) | Reserved | Reserved | Reserved |
| 32-255 | User Defined Interrupts | Yes | Yes | Yes |

**NOTE:**

* In the real-address mode, vector 13 is the segment overrun exception. In protected and virtual-8086 modes, this exception covers all general-protection error conditions, including traps to the virtual-8086 monitor from virtual-8086 mode.

## 20.2.1 Enabling Virtual-8086 Mode

The processor runs in virtual-8086 mode when the VM (virtual machine) flag in the EFLAGS register is set. This flag can only be set when the processor switches to a new protected-mode task or resumes virtual-8086 mode via an IRET instruction.

System software cannot change the state of the VM flag directly in the EFLAGS register (for example, by using the POPFD instruction). Instead it changes the flag in the image of the EFLAGS register stored in the TSS or on the stack following a call to an interrupt- or exception-handler procedure. For example, software sets the VM flag in the EFLAGS image in the TSS when first creating a virtual-8086 task.

The processor tests the VM flag under three general conditions:

- When loading segment registers, to determine whether to use 8086-style address translation.
- When decoding instructions, to determine which instructions are not supported in virtual-8086 mode and which instructions are sensitive to IOPL.

- When checking privileged instructions, on page accesses, or when performing other permission checks. (Virtual-8086 mode always executes at CPL 3.)

### 20.2.2 Structure of a Virtual-8086 Task

A virtual-8086-mode task consists of the following items:

- A 32-bit TSS for the task.
- The 8086 program.
- A virtual-8086 monitor.
- 8086 operating-system services.

The TSS of the new task must be a 32-bit TSS, not a 16-bit TSS, because the 16-bit TSS does not load the most-significant word of the EFLAGS register, which contains the VM flag. All TSS's, stacks, data, and code used to handle exceptions when in virtual-8086 mode must also be 32-bit segments.

The processor enters virtual-8086 mode to run the 8086 program and returns to protected mode to run the virtual-8086 monitor.

The virtual-8086 monitor is a 32-bit protected-mode code module that runs at a CPL of 0. The monitor consists of initialization, interrupt- and exception-handling, and I/O emulation procedures that emulate a personal computer or other 8086-based platform. Typically, the monitor is either part of or closely associated with the protected-mode general-protection (#GP) exception handler, which also runs at a CPL of 0. As with any protected-mode code module, code-segment descriptors for the virtual-8086 monitor must exist in the GDT or in the task's LDT. The virtual-8086 monitor also may need data-segment descriptors so it can examine the IDT or other parts of the 8086 program in the first 1 MByte of the address space. The linear addresses above 10FFEFH are available for the monitor, the operating system, and other system software.

The 8086 operating-system services consists of a kernel and/or operating-system procedures that the 8086 program makes calls to. These services can be implemented in either of the following two ways:

- They can be included in the 8086 program. This approach is desirable for either of the following reasons:
  - The 8086 program code modifies the 8086 operating-system services.
  - There is not sufficient development time to merge the 8086 operating-system services into main operating system or executive.
- They can be implemented or emulated in the virtual-8086 monitor. This approach is desirable for any of the following reasons:
  - The 8086 operating-system procedures can be more easily coordinated among several virtual-8086 tasks.
  - Memory can be saved by not duplicating 8086 operating-system procedure code for several virtual-8086 tasks.
  - The 8086 operating-system procedures can be easily emulated by calls to the main operating system or executive.

The approach chosen for implementing the 8086 operating-system services may result in different virtual-8086-mode tasks using different 8086 operating-system services.

### 20.2.3 Paging of Virtual-8086 Tasks

Even though a program running in virtual-8086 mode can use only 20-bit linear addresses, the processor converts these addresses into 32-bit linear addresses before mapping them to the physical address space. If paging is being used, the 8086 address space for a program running in virtual-8086 mode can be paged and located in a set of pages in physical address space. If paging is used, it is transparent to the program running in virtual-8086 mode just as it is for any task running on the processor.

Paging is not necessary for a single virtual-8086-mode task, but paging is useful or necessary in the following situations:

- When running multiple virtual-8086-mode tasks. Here, paging allows the lower 1 MByte of the linear address space for each virtual-8086-mode task to be mapped to a different physical address location.
- When emulating the 8086 address-wraparound that occurs at 1 MByte. When using 8086-style address translation, it is possible to specify addresses larger than 1 MByte. These addresses automatically wraparound in the Intel 8086 processor (see Section 20.1.1, "Address Translation in Real-Address Mode"). If any 8086 programs depend on address wraparound, the same effect can be achieved in a virtual-8086-mode task by mapping the linear addresses between 100000H and 110000H and linear addresses between 0 and 10000H to the same physical addresses.
- When sharing the 8086 operating-system services or ROM code that is common to several 8086 programs running as different 8086-mode tasks.
- When redirecting or trapping references to memory-mapped I/O devices.

### 20.2.4 Protection within a Virtual-8086 Task

Protection is not enforced between the segments of an 8086 program. Either of the following techniques can be used to protect the system software running in a virtual-8086-mode task from the 8086 program:

- Reserve the first 1 MByte plus 64 KBytes of each task's linear address space for the 8086 program. An 8086 processor task cannot generate addresses outside this range.
- Use the U/S flag of page-table entries to protect the virtual-8086 monitor and other system software in the virtual-8086 mode task space. When the processor is in virtual-8086 mode, the CPL is 3. Therefore, an 8086 processor program has only user privileges. If the pages of the virtual-8086 monitor have supervisor privilege, they cannot be accessed by the 8086 program.

### 20.2.5 Entering Virtual-8086 Mode

Figure 20-3 summarizes the methods of entering and leaving virtual-8086 mode. The processor switches to virtual-8086 mode in either of the following situations:

- Task switch when the VM flag is set to 1 in the EFLAGS register image stored in the TSS for the task. Here the task switch can be initiated in either of two ways:
  - A CALL or JMP instruction.
  - An IRET instruction, where the NT flag in the EFLAGS image is set to 1.
- Return from a protected-mode interrupt or exception handler when the VM flag is set to 1 in the EFLAGS register image on the stack.

When a task switch is used to enter virtual-8086 mode, the TSS for the virtual-8086-mode task must be a 32-bit TSS. (If the new TSS is a 16-bit TSS, the upper word of the EFLAGS register is not in the TSS, causing the processor to clear the VM flag when it loads the EFLAGS register.) The processor updates the VM flag prior to loading the segment registers from their images in the new TSS. The new setting of the VM flag determines whether the processor interprets the contents of the segment registers as 8086-style segment selectors or protected-mode segment selectors. When the VM flag is set, the segment registers are loaded from the TSS, using 8086-style address translation to form base addresses.

See Section 20.3, "Interrupt and Exception Handling in Virtual-8086 Mode", for information on entering virtual-8086 mode on a return from an interrupt or exception handler.

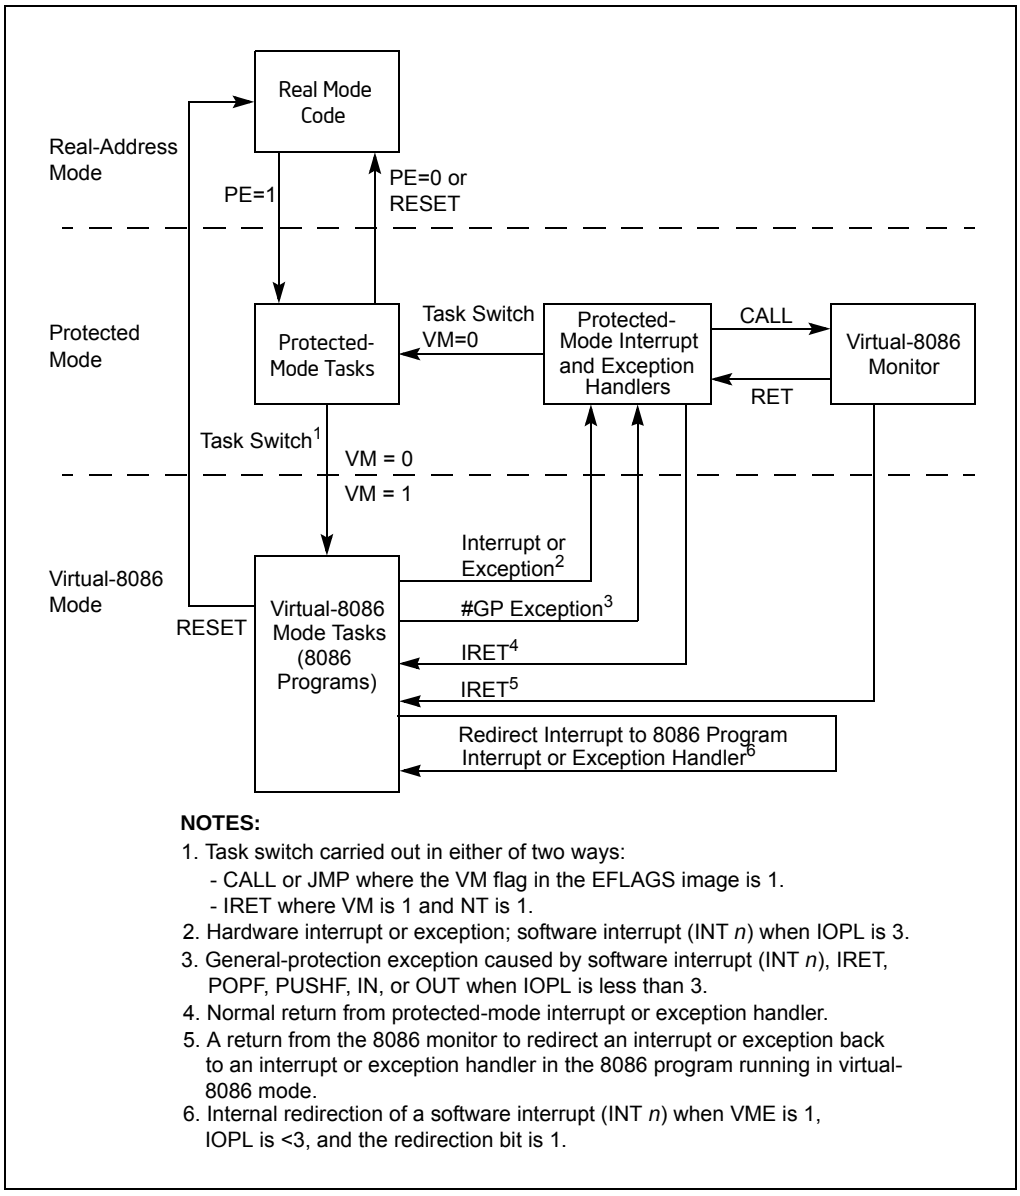

Figure 20-3. Entering and Leaving Virtual-8086 Mode

## 20.2.6 Leaving Virtual-8086 Mode

The processor can leave the virtual-8086 mode only through an interrupt or exception. The following are situations where an interrupt or exception will lead to the processor leaving virtual-8086 mode (see Figure 20-3):

- The processor services a hardware interrupt generated to signal the suspension of execution of the virtual-8086 application. This hardware interrupt may be generated by a timer or other external mechanism. Upon receiving the hardware interrupt, the processor enters protected mode and switches to a protected-mode (or another virtual-8086 mode) task either through a task gate in the protected-mode IDT or through a trap or interrupt gate that points to a handler that initiates a task switch. A task switch from a virtual-8086 task to another task loads the EFLAGS register from the TSS of the new task. The value of the VM flag in the new EFLAGS determines if the new task executes in virtual-8086 mode or not.
- The processor services an exception caused by code executing the virtual-8086 task or services a hardware interrupt that "belongs to" the virtual-8086 task. Here, the processor enters protected mode and services the

exception or hardware interrupt through the protected-mode IDT (normally through an interrupt or trap gate) and the protected-mode exception- and interrupt-handlers. The processor may handle the exception or interrupt within the context of the virtual 8086 task and return to virtual-8086 mode on a return from the handler procedure. The processor may also execute a task switch and handle the exception or interrupt in the context of another task.

- The processor services a software interrupt generated by code executing in the virtual-8086 task (such as a software interrupt to call a MS-DOS* operating system routine). The processor provides several methods of handling these software interrupts, which are discussed in detail in Section 20.3.3, "Class 3—Software Interrupt Handling in Virtual-8086 Mode". Most of them involve the processor entering protected mode, often by means of a general-protection (#GP) exception. In protected mode, the processor can send the interrupt to the virtual-8086 monitor for handling and/or redirect the interrupt back to the application program running in virtual-8086 mode task for handling.

  IA-32 processors that incorporate the virtual mode extension (enabled with the VME flag in control register CR4) are capable of redirecting software-generated interrupts back to the program's interrupt handlers without leaving virtual-8086 mode. See Section 20.3.3.4, "Method 5: Software Interrupt Handling", for more information on this mechanism.
- A hardware reset initiated by asserting the RESET or INIT pin is a special kind of interrupt. When a RESET or INIT is signaled while the processor is in virtual-8086 mode, the processor leaves virtual-8086 mode and enters real-address mode.
- Execution of the HLT instruction in virtual-8086 mode will cause a general-protection (GP#) fault, which the protected-mode handler generally sends to the virtual-8086 monitor. The virtual-8086 monitor then determines the correct execution sequence after verifying that it was entered as a result of a HLT execution.

See Section 20.3, "Interrupt and Exception Handling in Virtual-8086 Mode", for information on leaving virtual-8086 mode to handle an interrupt or exception generated in virtual-8086 mode.

### 20.2.7 Sensitive Instructions

When an IA-32 processor is running in virtual-8086 mode, the CLI, STI, PUSHF, POPF, INT *n*, and IRET instructions are sensitive to IOPL. The IN, INS, OUT, and OUTS instructions, which are sensitive to IOPL in protected mode, are not sensitive in virtual-8086 mode.

The CPL is always 3 while running in virtual-8086 mode; if the IOPL is less than 3, an attempt to use the IOPL-sensitive instructions listed above triggers a general-protection exception (#GP). These instructions are sensitive to IOPL to give the virtual-8086 monitor a chance to emulate the facilities they affect.

### 20.2.8 Virtual-8086 Mode I/O

Many 8086 programs written for non-multitasking systems directly access I/O ports. This practice may cause problems in a multitasking environment. If more than one program accesses the same port, they may interfere with each other. Most multitasking systems require application programs to access I/O ports through the operating system. This results in simplified, centralized control.

The processor provides I/O protection for creating I/O that is compatible with the environment and transparent to 8086 programs. Designers may take any of several possible approaches to protecting I/O ports:

- Protect the I/O address space and generate exceptions for all attempts to perform I/O directly.
- Let the 8086 program perform I/O directly.
- Generate exceptions on attempts to access specific I/O ports.
- Generate exceptions on attempts to access specific memory-mapped I/O ports.

The method of controlling access to I/O ports depends upon whether they are I/O-port mapped or memory mapped.

### 20.2.8.1 I/O-Port-Mapped I/O

The I/O permission bit map in the TSS can be used to generate exceptions on attempts to access specific I/O port addresses. The I/O permission bit map of each virtual-8086-mode task determines which I/O addresses generate exceptions for that task. Because each task may have a different I/O permission bit map, the addresses that generate exceptions for one task may be different from the addresses for another task. This differs from protected mode in which, if the CPL is less than or equal to the IOPL, I/O access is allowed without checking the I/O permission bit map. See Chapter 16, "Input/Output", in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, for more information about the I/O permission bit map.

### 20.2.8.2 Memory-Mapped I/O

In systems which use memory-mapped I/O, the paging facilities of the processor can be used to generate exceptions for attempts to access I/O ports. The virtual-8086 monitor may use paging to control memory-mapped I/O in these ways:

- Map part of the linear address space of each task that needs to perform I/O to the physical address space where I/O ports are placed. By putting the I/O ports at different addresses (in different pages), the paging mechanism can enforce isolation between tasks.
- Map part of the linear address space to pages that are not-present. This generates an exception whenever a task attempts to perform I/O to those pages. System software then can interpret the I/O operation being attempted.

Software emulation of the I/O space may require too much operating system intervention under some conditions. In these cases, it may be possible to generate an exception for only the first attempt to access I/O. The system software then may determine whether a program can be given exclusive control of I/O temporarily, the protection of the I/O space may be lifted, and the program allowed to run at full speed.

### 20.2.8.3 Special I/O Buffers

Buffers of intelligent controllers (for example, a bit-mapped frame buffer) also can be emulated using page mapping. The linear space for the buffer can be mapped to a different physical space for each virtual-8086-mode task. The virtual-8086 monitor then can control which virtual buffer to copy onto the real buffer in the physical address space.

## 20.3 INTERRUPT AND EXCEPTION HANDLING IN VIRTUAL-8086 MODE

When the processor receives an interrupt or detects an exception condition while in virtual-8086 mode, it invokes an interrupt or exception handler, just as it does in protected or real-address mode. The interrupt or exception handler that is invoked and the mechanism used to invoke it depends on the class of interrupt or exception that has been detected or generated and the state of various system flags and fields.

In virtual-8086 mode, the interrupts and exceptions are divided into three classes for the purposes of handling:

- **Class 1** — All processor-generated exceptions and all hardware interrupts, including the NMI interrupt and the hardware interrupts sent to the processor's external interrupt delivery pins. All class 1 exceptions and interrupts are handled by the protected-mode exception and interrupt handlers.
- **Class 2** — Special case for maskable hardware interrupts (Section 6.3.2, "Maskable Hardware Interrupts") when the virtual mode extensions are enabled.
- **Class 3** — All software-generated interrupts, that is interrupts generated with the INT *n* instruction[1].

The method the processor uses to handle class 2 and 3 interrupts depends on the setting of the following flags and fields:

- **IOPL field (bits 12 and 13 in the EFLAGS register)** — Controls how class 3 software interrupts are handled when the processor is in virtual-8086 mode (see Section 2.3, "System Flags and Fields in the EFLAGS

1. The INT 3 instruction is a special case (see the description of the INT *n* instruction in Chapter 3, "Instruction Set Reference, A-M", of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*).

Register"). This field also controls the enabling of the VIF and VIP flags in the EFLAGS register when the VME flag is set. The VIF and VIP flags are provided to assist in the handling of class 2 maskable hardware interrupts.

- **VME flag (bit 0 in control register CR4)** — Enables the virtual mode extension for the processor when set (see Section 2.5, "Control Registers").
- **Software interrupt redirection bit map (32 bytes in the TSS, see Figure 20-5)** — Contains 256 flags that indicates how class 3 software interrupts should be handled when they occur in virtual-8086 mode. A software interrupt can be directed either to the interrupt and exception handlers in the currently running 8086 program or to the protected-mode interrupt and exception handlers.
- **The virtual interrupt flag (VIF) and virtual interrupt pending flag (VIP) in the EFLAGS register** — Provides **virtual interrupt support** for the handling of class 2 maskable hardware interrupts (see Section 20.3.2, "Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism").

**NOTE**

The VME flag, software interrupt redirection bit map, and VIF and VIP flags are only available in IA-32 processors that support the virtual mode extensions. These extensions were introduced in the IA-32 architecture with the Pentium processor.

The following sections describe the actions that processor takes and the possible actions of interrupt and exception handlers for the two classes of interrupts described in the previous paragraphs. These sections describe three possible types of interrupt and exception handlers:

- **Protected-mode interrupt and exceptions handlers** — These are the standard handlers that the processor calls through the protected-mode IDT.
- **Virtual-8086 monitor interrupt and exception handlers** — These handlers are resident in the virtual-8086 monitor, and they are commonly accessed through a general-protection exception (#GP, interrupt 13) that is directed to the protected-mode general-protection exception handler.
- **8086 program interrupt and exception handlers** — These handlers are part of the 8086 program that is running in virtual-8086 mode.

The following sections describe how these handlers are used, depending on the selected class and method of interrupt and exception handling.

## 20.3.1 Class 1—Hardware Interrupt and Exception Handling in Virtual-8086 Mode

In virtual-8086 mode, the Pentium, P6 family, Pentium 4, and Intel Xeon processors handle hardware interrupts and exceptions in the same manner as they are handled by the Intel486 and Intel386 processors. They invoke the protected-mode interrupt or exception handler that the interrupt or exception vector points to in the IDT. Here, the IDT entry must contain either a 32-bit trap or interrupt gate or a task gate. The following sections describe various ways that a virtual-8086 mode interrupt or exception can be handled after the protected-mode handler has been invoked.

See Section 20.3.2, "Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism", for a description of the virtual interrupt mechanism that is available for handling maskable hardware interrupts while in virtual-8086 mode. When this mechanism is either not available or not enabled, maskable hardware interrupts are handled in the same manner as exceptions, as described in the following sections.

### 20.3.1.1 Handling an Interrupt or Exception Through a Protected-Mode Trap or Interrupt Gate

When an interrupt or exception vector points to a 32-bit trap or interrupt gate in the IDT, the gate must in turn point to a nonconforming, privilege-level 0, code segment. When accessing this code segment, processor performs the following steps.

1. Switches to 32-bit protected mode and privilege level 0.
2. Saves the state of the processor on the privilege-level 0 stack. The states of the EIP, CS, EFLAGS, ESP, SS, ES, DS, FS, and GS registers are saved (see Figure 20-4).

3. Clears the segment registers. Saving the DS, ES, FS, and GS registers on the stack and then clearing the registers lets the interrupt or exception handler safely save and restore these registers regardless of the type segment selectors they contain (protected-mode or 8086-style). The interrupt and exception handlers, which may be called in the context of either a protected-mode task or a virtual-8086-mode task, can use the same code sequences for saving and restoring the registers for any task. Clearing these registers before execution of the IRET instruction does not cause a trap in the interrupt handler. Interrupt procedures that expect values in the segment registers or that return values in the segment registers must use the register images saved on the stack for privilege level 0.
4. Clears VM, NT, RF and TF flags (in the EFLAGS register). If the gate is an interrupt gate, clears the IF flag.
5. Begins executing the selected interrupt or exception handler.

If the trap or interrupt gate references a procedure in a conforming segment or in a segment at a privilege level other than 0, the processor generates a general-protection exception (#GP). Here, the error code is the segment selector of the code segment to which a call was attempted.

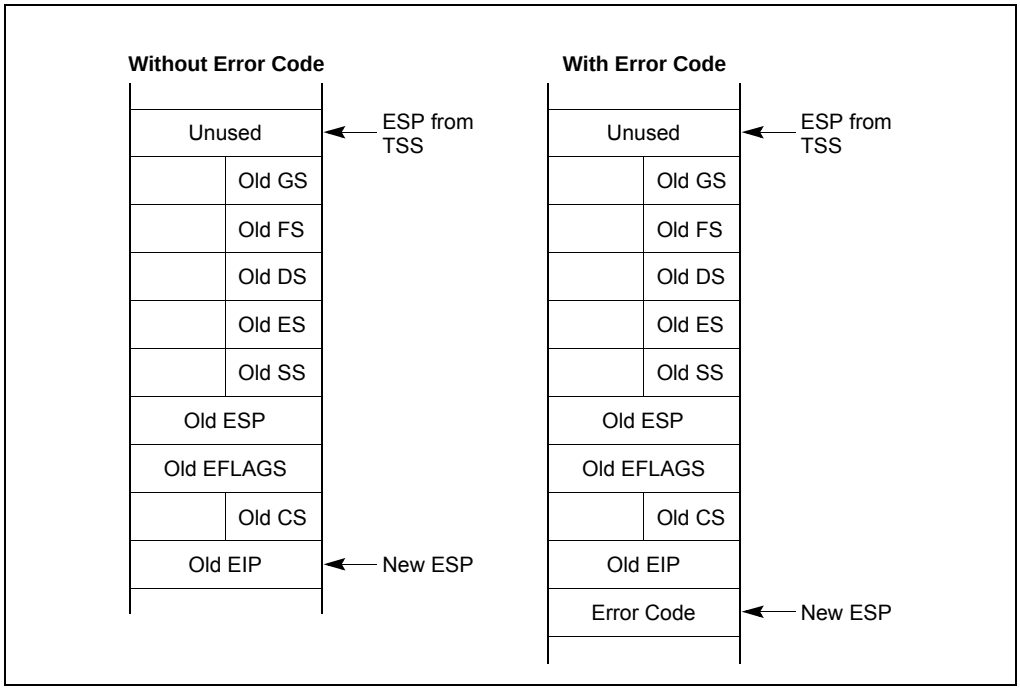

**Figure 20-4. Privilege Level 0 Stack After Interrupt or Exception in Virtual-8086 Mode**

Interrupt and exception handlers can examine the VM flag on the stack to determine if the interrupted procedure was running in virtual-8086 mode. If so, the interrupt or exception can be handled in one of three ways:

- The protected-mode interrupt or exception handler that was called can handle the interrupt or exception.
- The protected-mode interrupt or exception handler can call the virtual-8086 monitor to handle the interrupt or exception.
- The virtual-8086 monitor (if called) can in turn pass control back to the 8086 program's interrupt and exception handler.

If the interrupt or exception is handled with a protected-mode handler, the handler can return to the interrupted program in virtual-8086 mode by executing an IRET instruction. This instruction loads the EFLAGS and segment registers from the images saved in the privilege level 0 stack (see Figure 20-4). A set VM flag in the EFLAGS image causes the processor to switch back to virtual-8086 mode. The CPL at the time the IRET instruction is executed must be 0, otherwise the processor does not change the state of the VM flag.

The virtual-8086 monitor runs at privilege level 0, like the protected-mode interrupt and exception handlers. It is commonly closely tied to the protected-mode general-protection exception (#GP, vector 13) handler. If the protected-mode interrupt or exception handler calls the virtual-8086 monitor to handle the interrupt or exception, the return from the virtual-8086 monitor to the interrupted virtual-8086 mode program requires two return instructions: a RET instruction to return to the protected-mode handler and an IRET instruction to return to the interrupted program.

The virtual-8086 monitor has the option of directing the interrupt and exception back to an interrupt or exception handler that is part of the interrupted 8086 program, as described in Section 20.3.1.2, "Handling an Interrupt or Exception With an 8086 Program Interrupt or Exception Handler".

### 20.3.1.2 Handling an Interrupt or Exception With an 8086 Program Interrupt or Exception Handler

Because it was designed to run on an 8086 processor, an 8086 program running in a virtual-8086-mode task contains an 8086-style interrupt vector table, which starts at linear address 0. If the virtual-8086 monitor correctly directs an interrupt or exception vector back to the virtual-8086-mode task it came from, the handlers in the 8086 program can handle the interrupt or exception. The virtual-8086 monitor must carry out the following steps to send an interrupt or exception back to the 8086 program:

1. Use the 8086 interrupt vector to locate the appropriate handler procedure in the 8086 program interrupt table.
2. Store the EFLAGS (low-order 16 bits only), CS and EIP values of the 8086 program on the privilege-level 3 stack. This is the stack that the virtual-8086-mode task is using. (The 8086 handler may use or modify this information.)
3. Change the return link on the privilege-level 0 stack to point to the privilege-level 3 handler procedure.
4. Execute an IRET instruction to pass control to the 8086 program handler.
5. When the IRET instruction from the privilege-level 3 handler triggers a general-protection exception (#GP) and thus effectively again calls the virtual-8086 monitor, restore the return link on the privilege-level 0 stack to point to the original, interrupted, privilege-level 3 procedure.
6. Copy the low order 16 bits of the EFLAGS image from the privilege-level 3 stack to the privilege-level 0 stack (because some 8086 handlers modify these flags to return information to the code that caused the interrupt).
7. Execute an IRET instruction to pass control back to the interrupted 8086 program.

Note that if an operating system intends to support all 8086 MS-DOS-based programs, it is necessary to use the actual 8086 interrupt and exception handlers supplied with the program. The reason for this is that some programs modify their own interrupt vector table to substitute (or hook in series) their own specialized interrupt and exception handlers.

### 20.3.1.3 Handling an Interrupt or Exception Through a Task Gate

When an interrupt or exception vector points to a task gate in the IDT, the processor performs a task switch to the selected interrupt- or exception-handling task. The following actions are carried out as part of this task switch:

1. The EFLAGS register with the VM flag set is saved in the current TSS.
2. The link field in the TSS of the called task is loaded with the segment selector of the TSS for the interrupted virtual-8086-mode task.
3. The EFLAGS register is loaded from the image in the new TSS, which clears the VM flag and causes the processor to switch to protected mode.
4. The NT flag in the EFLAGS register is set.
5. The processor begins executing the selected interrupt- or exception-handler task.

When an IRET instruction is executed in the handler task and the NT flag in the EFLAGS register is set, the processors switches from a protected-mode interrupt- or exception-handler task back to a virtual-8086-mode task. Here, the EFLAGS and segment registers are loaded from images saved in the TSS for the virtual-8086-mode task. If the VM flag is set in the EFLAGS image, the processor switches back to virtual-8086 mode on the task switch. The CPL at the time the IRET instruction is executed must be 0, otherwise the processor does not change the state of the VM flag.

### 20.3.2 Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism

Maskable hardware interrupts are those interrupts that are delivered through the INTR# pin or through an interrupt request to the local APIC (see Section 6.3.2, "Maskable Hardware Interrupts"). These interrupts can be inhibited (masked) from interrupting an executing program or task by clearing the IF flag in the EFLAGS register.

When the VME flag in control register CR4 is set and the IOPL field in the EFLAGS register is less than 3, two additional flags are activated in the EFLAGS register:

- VIF (virtual interrupt) flag, bit 19 of the EFLAGS register.
- VIP (virtual interrupt pending) flag, bit 20 of the EFLAGS register.

These flags provide the virtual-8086 monitor with more efficient control over handling maskable hardware interrupts that occur during virtual-8086 mode tasks. They also reduce interrupt-handling overhead, by eliminating the need for all IF related operations (such as PUSHF, POPF, CLI, and STI instructions) to trap to the virtual-8086 monitor. The purpose and use of these flags are as follows.

**NOTE**

The VIF and VIP flags are only available in IA-32 processors that support the virtual mode extensions. These extensions were introduced in the IA-32 architecture with the Pentium processor. When this mechanism is either not available or not enabled, maskable hardware interrupts are handled as class 1 interrupts. Here, if VIF and VIP flags are needed, the virtual-8086 monitor can implement them in software.

Existing 8086 programs commonly set and clear the IF flag in the EFLAGS register to enable and disable maskable hardware interrupts, respectively; for example, to disable interrupts while handling another interrupt or an exception. This practice works well in single task environments, but can cause problems in multitasking and multiple-processor environments, where it is often desirable to prevent an application program from having direct control over the handling of hardware interrupts. When using earlier IA-32 processors, this problem was often solved by creating a virtual IF flag in software. The IA-32 processors (beginning with the Pentium processor) provide hardware support for this virtual IF flag through the VIF and VIP flags.

The VIF flag is a virtualized version of the IF flag, which an application program running from within a virtual-8086 task can used to control the handling of maskable hardware interrupts. When the VIF flag is enabled, the CLI and STI instructions operate on the VIF flag instead of the IF flag. When an 8086 program executes the CLI instruction, the processor clears the VIF flag to request that the virtual-8086 monitor inhibit maskable hardware interrupts from interrupting program execution; when it executes the STI instruction, the processor sets the VIF flag requesting that the virtual-8086 monitor enable maskable hardware interrupts for the 8086 program. But actually the IF flag, managed by the operating system, always controls whether maskable hardware interrupts are enabled. Also, if under these circumstances an 8086 program tries to read or change the IF flag using the PUSHF or POPF instructions, the processor will change the VIF flag instead, leaving IF unchanged.

The VIP flag provides software a means of recording the existence of a deferred (or pending) maskable hardware interrupt. This flag is read by the processor but never explicitly written by the processor; it can only be written by software.

If the IF flag is set and the VIF and VIP flags are enabled, and the processor receives a maskable hardware interrupt (interrupt vector 0 through 255), the processor performs and the interrupt handler software should perform the following operations:

1. The processor invokes the protected-mode interrupt handler for the interrupt received, as described in the following steps. These steps are almost identical to those described for method 1 interrupt and exception handling in Section 20.3.1.1, "Handling an Interrupt or Exception Through a Protected-Mode Trap or Interrupt Gate":
   a. Switches to 32-bit protected mode and privilege level 0.
   b. Saves the state of the processor on the privilege-level 0 stack. The states of the EIP, CS, EFLAGS, ESP, SS, ES, DS, FS, and GS registers are saved (see Figure 20-4).
   c. Clears the segment registers.

d. Clears the VM flag in the EFLAGS register.

e. Begins executing the selected protected-mode interrupt handler.

2. The recommended action of the protected-mode interrupt handler is to read the VM flag from the EFLAGS image on the stack. If this flag is set, the handler makes a call to the virtual-8086 monitor.

3. The virtual-8086 monitor should read the VIF flag in the EFLAGS register.

   — If the VIF flag is clear, the virtual-8086 monitor sets the VIP flag in the EFLAGS image on the stack to indicate that there is a deferred interrupt pending and returns to the protected-mode handler.

   — If the VIF flag is set, the virtual-8086 monitor can handle the interrupt if it "belongs" to the 8086 program running in the interrupted virtual-8086 task; otherwise, it can call the protected-mode interrupt handler to handle the interrupt.

4. The protected-mode handler executes a return to the program executing in virtual-8086 mode.

5. Upon returning to virtual-8086 mode, the processor continues execution of the 8086 program.

When the 8086 program is ready to receive maskable hardware interrupts, it executes the STI instruction to set the VIF flag (enabling maskable hardware interrupts). Prior to setting the VIF flag, the processor automatically checks the VIP flag and does one of the following, depending on the state of the flag:

- If the VIP flag is clear (indicating no pending interrupts), the processor sets the VIF flag.
- If the VIP flag is set (indicating a pending interrupt), the processor generates a general-protection exception (#GP).

The recommended action of the protected-mode general-protection exception handler is to then call the virtual-8086 monitor and let it handle the pending interrupt. After handling the pending interrupt, the typical action of the virtual-8086 monitor is to clear the VIP flag and set the VIF flag in the EFLAGS image on the stack, and then execute a return to the virtual-8086 mode. The next time the processor receives a maskable hardware interrupt, it will then handle it as described in steps 1 through 5 earlier in this section.

If the processor finds that both the VIF and VIP flags are set at the beginning of an instruction, it generates a general-protection exception. This action allows the virtual-8086 monitor to handle the pending interrupt for the virtual-8086 mode task for which the VIF flag is enabled. Note that this situation can only occur immediately following execution of a POPF or IRET instruction or upon entering a virtual-8086 mode task through a task switch.

Note that the states of the VIF and VIP flags are not modified in real-address mode or during transitions between real-address and protected modes.

**NOTE**

The virtual interrupt mechanism described in this section is also available for use in protected mode, see Section 20.4, "Protected-Mode Virtual Interrupts".

### 20.3.3 Class 3—Software Interrupt Handling in Virtual-8086 Mode

When the processor receives a software interrupt (an interrupt generated with the INT *n* instruction) while in virtual-8086 mode, it can use any of six different methods to handle the interrupt. The method selected depends on the settings of the VME flag in control register CR4, the IOPL field in the EFLAGS register, and the software interrupt redirection bit map in the TSS. Table 20-2 lists the six methods of handling software interrupts in virtual-8086 mode and the respective settings of the VME flag, IOPL field, and the bits in the interrupt redirection bit map for each method. The table also summarizes the various actions the processor takes for each method.

The VME flag enables the virtual mode extensions for the Pentium and later IA-32 processors. When this flag is clear, the processor responds to interrupts and exceptions in virtual-8086 mode in the same manner as an Intel386 or Intel486 processor does. When this flag is set, the virtual mode extension provides the following enhancements to virtual-8086 mode:

- Speeds up the handling of software-generated interrupts in virtual-8086 mode by allowing the processor to bypass the virtual-8086 monitor and redirect software interrupts back to the interrupt handlers that are part of the currently running 8086 program.
- Supports virtual interrupts for software written to run on the 8086 processor.

The IOPL value interacts with the VME flag and the bits in the interrupt redirection bit map to determine how specific software interrupts should be handled.

The software interrupt redirection bit map (see Figure 20-5) is a 32-byte field in the TSS. This map is located directly below the I/O permission bit map in the TSS. Each bit in the interrupt redirection bit map is mapped to an interrupt vector. Bit 0 in the interrupt redirection bit map (which maps to vector zero in the interrupt table) is located at the I/O base map address in the TSS minus 32 bytes. When a bit in this bit map is set, it indicates that the associated software interrupt (interrupt generated with an INT *n* instruction) should be handled through the protected-mode IDT and interrupt and exception handlers. When a bit in this bit map is clear, the processor redirects the associated software interrupt back to the interrupt table in the 8086 program (located at linear address 0 in the program's address space).

## NOTE

The software interrupt redirection bit map does not affect hardware generated interrupts and exceptions. Hardware generated interrupts and exceptions are always handled by the protected-mode interrupt and exception handlers.

**Table 20-2. Software Interrupt Handling Methods While in Virtual-8086 Mode**

| Method | VME | IOPL | Bit in Redir. Bitmap* | Processor Action |
|---|---|---|---|---|
| 1 | 0 | 3 | X | Interrupt directed to a protected-mode interrupt handler:<br>▪ Switches to privilege-level 0 stack<br>▪ Pushes GS, FS, DS and ES onto privilege-level 0 stack<br>▪ Pushes SS, ESP, EFLAGS, CS and EIP of interrupted task onto privilege-level 0 stack<br>▪ Clears VM, RF, NT, and TF flags<br>▪ If serviced through interrupt gate, clears IF flag<br>▪ Clears GS, FS, DS and ES to 0<br>▪ Sets CS and EIP from interrupt gate |
| 2 | 0 | < 3 | X | Interrupt directed to protected-mode general-protection exception (#GP) handler. |
| 3 | 1 | < 3 | 1 | Interrupt directed to a protected-mode general-protection exception (#GP) handler; VIF and VIP flag support for handling class 2 maskable hardware interrupts. |
| 4 | 1 | 3 | 1 | Interrupt directed to protected-mode interrupt handler: (see method 1 processor action). |
| 5 | 1 | 3 | 0 | Interrupt redirected to 8086 program interrupt handler:<br>▪ Pushes EFLAGS<br>▪ Pushes CS and EIP (lower 16 bits only)<br>▪ Clears IF flag<br>▪ Clears TF flag<br>▪ Loads CS and EIP (lower 16 bits only) from selected entry in the interrupt vector table of the current virtual-8086 task |
| 6 | 1 | < 3 | 0 | Interrupt redirected to 8086 program interrupt handler; VIF and VIP flag support for handling class 2 maskable hardware interrupts:<br>▪ Pushes EFLAGS with IOPL set to 3 and VIF copied to IF<br>▪ Pushes CS and EIP (lower 16 bits only)<br>▪ Clears the VIF flag<br>▪ Clears TF flag<br>▪ Loads CS and EIP (lower 16 bits only) from selected entry in the interrupt vector table of the current virtual-8086 task |

**NOTE:**

* When set to 0, software interrupt is redirected back to the 8086 program interrupt handler; when set to 1, interrupt is directed to protected-mode handler.

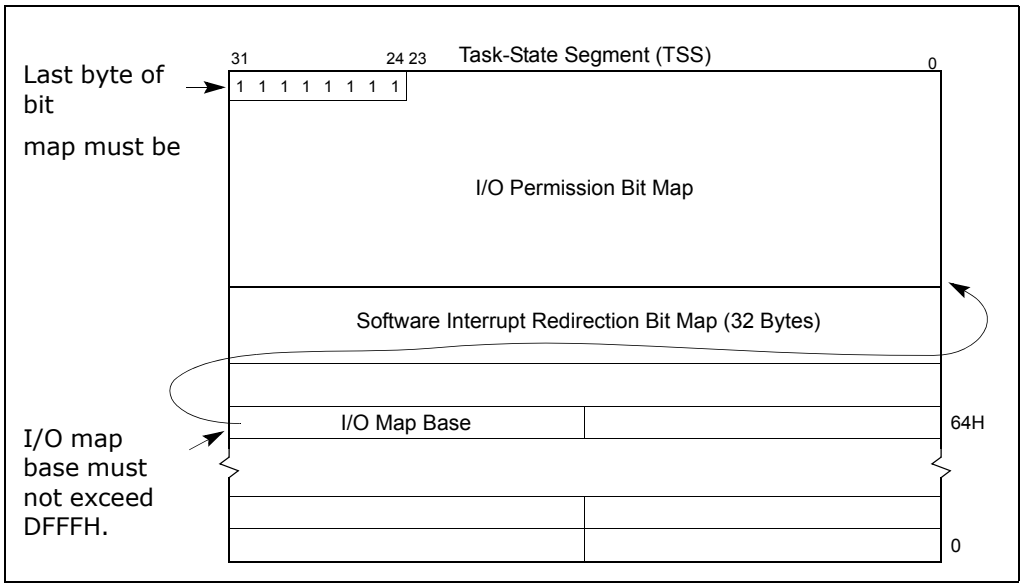

**Figure 20-5. Software Interrupt Redirection Bit Map in TSS**

Redirecting software interrupts back to the 8086 program potentially speeds up interrupt handling because a switch back and forth between virtual-8086 mode and protected mode is not required. This latter interrupt-handling technique is particularly useful for 8086 operating systems (such as MS-DOS) that use the INT *n* instruction to call operating system procedures.

The CPUID instruction can be used to verify that the virtual mode extension is implemented on the processor. Bit 1 of the feature flags register (EDX) indicates the availability of the virtual mode extension (see "CPUID—CPU Identification" in Chapter 3, "Instruction Set Reference, A-M", of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*).

The following sections describe the six methods (or mechanisms) for handling software interrupts in virtual-8086 mode. See Section 20.3.2, "Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism", for a description of the use of the VIF and VIP flags in the EFLAGS register for handling maskable hardware interrupts.

### 20.3.3.1 Method 1: Software Interrupt Handling

When the VME flag in control register CR4 is clear and the IOPL field is 3, a Pentium or later IA-32 processor handles software interrupts in the same manner as they are handled by an Intel386 or Intel486 processor. It executes an implicit call to the interrupt handler in the protected-mode IDT pointed to by the interrupt vector. See Section 20.3.1, "Class 1—Hardware Interrupt and Exception Handling in Virtual-8086 Mode", for a complete description of this mechanism and its possible uses.

### 20.3.3.2 Methods 2 and 3: Software Interrupt Handling

When a software interrupt occurs in virtual-8086 mode and the method 2 or 3 conditions are present, the processor generates a general-protection exception (#GP). Method 2 is enabled when the VME flag is set to 0 and the IOPL value is less than 3. Here the IOPL value is used to bypass the protected-mode interrupt handlers and cause any software interrupt that occurs in virtual-8086 mode to be treated as a protected-mode general-protection exception (#GP). The general-protection exception handler calls the virtual-8086 monitor, which can then emulate an 8086-program interrupt handler or pass control back to the 8086 program's handler, as described in Section 20.3.1.2, "Handling an Interrupt or Exception With an 8086 Program Interrupt or Exception Handler".

Method 3 is enabled when the VME flag is set to 1, the IOPL value is less than 3, and the corresponding bit for the software interrupt in the software interrupt redirection bit map is set to 1. Here, the processor performs the same

operation as it does for method 2 software interrupt handling. If the corresponding bit for the software interrupt in the software interrupt redirection bit map is set to 0, the interrupt is handled using method 6 (see Section 20.3.3.5, "Method 6: Software Interrupt Handling").

### 20.3.3.3 Method 4: Software Interrupt Handling

Method 4 handling is enabled when the VME flag is set to 1, the IOPL value is 3, and the bit for the interrupt vector in the redirection bit map is set to 1. Method 4 software interrupt handling allows method 1 style handling when the virtual mode extension is enabled; that is, the interrupt is directed to a protected-mode handler (see Section 20.3.3.1, "Method 1: Software Interrupt Handling").

### 20.3.3.4 Method 5: Software Interrupt Handling

Method 5 software interrupt handling provides a streamlined method of redirecting software interrupts (invoked with the INT *n* instruction) that occur in virtual 8086 mode back to the 8086 program's interrupt vector table and its interrupt handlers. Method 5 handling is enabled when the VME flag is set to 1, the IOPL value is 3, and the bit for the interrupt vector in the redirection bit map is set to 0. The processor performs the following actions to make an implicit call to the selected 8086 program interrupt handler:

1. Pushes the low-order 16 bits of the EFLAGS register onto the stack.
2. Pushes the current values of the CS and EIP registers onto the current stack. (Only the 16 least-significant bits of the EIP register are pushed and no stack switch occurs.)
3. Clears the IF flag in the EFLAGS register to disable interrupts.
4. Clears the TF flag, in the EFLAGS register.
5. Locates the 8086 program interrupt vector table at linear address 0 for the 8086-mode task.
6. Loads the CS and EIP registers with values from the interrupt vector table entry pointed to by the interrupt vector number. Only the 16 low-order bits of the EIP are loaded and the 16 high-order bits are set to 0. The interrupt vector table is assumed to be at linear address 0 of the current virtual-8086 task.
7. Begins executing the selected interrupt handler.

An IRET instruction at the end of the handler procedure reverses these steps to return program control to the interrupted 8086 program.

Note that with method 5 handling, a mode switch from virtual-8086 mode to protected mode does not occur. The processor remains in virtual-8086 mode throughout the interrupt-handling operation.

The method 5 handling actions are virtually identical to the actions the processor takes when handling software interrupts in real-address mode. The benefit of using method 5 handling to access the 8086 program handlers is that it avoids the overhead of methods 2 and 3 handling, which requires first going to the virtual-8086 monitor, then to the 8086 program handler, then back again to the virtual-8086 monitor, before returning to the interrupted 8086 program (see Section 20.3.1.2, "Handling an Interrupt or Exception With an 8086 Program Interrupt or Exception Handler").

**NOTE**

Methods 1 and 4 handling can handle a software interrupt in a virtual-8086 task with a regular protected-mode handler, but this approach requires all virtual-8086 tasks to use the same software interrupt handlers, which generally does not give sufficient latitude to the programs running in the virtual-8086 tasks, particularly MS-DOS programs.

### 20.3.3.5 Method 6: Software Interrupt Handling

Method 6 handling is enabled when the VME flag is set to 1, the IOPL value is less than 3, and the bit for the interrupt or exception vector in the redirection bit map is set to 0. With method 6 interrupt handling, software interrupts are handled in the same manner as was described for method 5 handling (see Section 20.3.3.4, "Method 5: Software Interrupt Handling").

Method 6 differs from method 5 in that with the IOPL value set to less than 3, the VIF and VIP flags in the EFLAGS register are enabled, providing virtual interrupt support for handling class 2 maskable hardware interrupts (see Section 20.3.2, "Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism"). These flags provide the virtual-8086 monitor with an efficient means of handling maskable hardware interrupts that occur during a virtual-8086 mode task. Also, because the IOPL value is less than 3 and the VIF flag is enabled, the information pushed on the stack by the processor when invoking the interrupt handler is slightly different between methods 5 and 6 (see Table 20-2).

## 20.4 PROTECTED-MODE VIRTUAL INTERRUPTS

The IA-32 processors (beginning with the Pentium processor) also support the VIF and VIP flags in the EFLAGS register in protected mode by setting the PVI (protected-mode virtual interrupt) flag in the CR4 register. Setting the PVI flag allows applications running at privilege level 3 to execute the CLI and STI instructions without causing a general-protection exception (#GP) or affecting hardware interrupts.

When the PVI flag is set to 1, the CPL is 3, and the IOPL is less than 3, the STI and CLI instructions set and clear the VIF flag in the EFLAGS register, leaving IF unaffected. In this mode of operation, an application running in protected mode and at a CPL of 3 can inhibit interrupts in the same manner as is described in Section 20.3.2, "Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism", for a virtual-8086 mode task. When the application executes the CLI instruction, the processor clears the VIF flag. If the processor receives a maskable hardware interrupt, the processor invokes the protected-mode interrupt handler. This handler checks the state of the VIF flag in the EFLAGS register. If the VIF flag is clear (indicating that the active task does not want to have interrupts handled now), the handler sets the VIP flag in the EFLAGS image on the stack and returns to the privilege-level 3 application, which continues program execution. When the application executes a STI instruction to set the VIF flag, the processor automatically invokes the general-protection exception handler, which can then handle the pending interrupt. After handing the pending interrupt, the handler typically sets the VIF flag and clears the VIP flag in the EFLAGS image on the stack and executes a return to the application program. The next time the processor receives a maskable hardware interrupt, the processor will handle it in the normal manner for interrupts received while the processor is operating at a CPL of 3.

As with the virtual mode extension (enabled with the VME flag in the CR4 register), the protected-mode virtual interrupt extension only affects maskable hardware interrupts (interrupt vectors 32 through 255). NMI interrupts and exceptions are handled in the normal manner.

When protected-mode virtual interrupts are disabled (that is, when the PVI flag in control register CR4 is set to 0, the CPL is less than 3, or the IOPL value is 3), then the CLI and STI instructions execute in a manner compatible with the Intel486 processor. That is, if the CPL is greater (less privileged) than the I/O privilege level (IOPL), a general-protection exception occurs. If the IOPL value is 3, CLI and STI clear or set the IF flag, respectively.

PUSHF, POPF, IRET and INT are executed like in the Intel486 processor, regardless of whether protected-mode virtual interrupts are enabled.

It is only possible to enter virtual-8086 mode through a task switch or the execution of an IRET instruction, and it is only possible to leave virtual-8086 mode by faulting to a protected-mode interrupt handler (typically the general-protection exception handler, which in turn calls the virtual 8086-mode monitor). In both cases, the EFLAGS register is saved and restored. This is not true, however, in protected mode when the PVI flag is set and the processor is not in virtual-8086 mode. Here, it is possible to call a procedure at a different privilege level, in which case the EFLAGS register is not saved or modified. However, the states of VIF and VIP flags are never examined by the processor when the CPL is not 3.

# CHAPTER 21
# MIXING 16-BIT AND 32-BIT CODE

Program modules written to run on IA-32 processors can be either 16-bit modules or 32-bit modules. Table 21-1 shows the characteristic of 16-bit and 32-bit modules.

**Table 21-1. Characteristics of 16-Bit and 32-Bit Program Modules**

| Characteristic | 16-Bit Program Modules | 32-Bit Program Modules |
|---|---|---|
| Segment Size | 0 to 64 KBytes | 0 to 4 GBytes |
| Operand Sizes | 8 bits and 16 bits | 8 bits and 32 bits |
| Pointer Offset Size (Address Size) | 16 bits | 32 bits |
| Stack Pointer Size | 16 Bits | 32 Bits |
| Control Transfers Allowed to Code Segments of This Size | 16 Bits | 32 Bits |

The IA-32 processors function most efficiently when executing 32-bit program modules. They can, however, also execute 16-bit program modules, in any of the following ways:

- In real-address mode.
- In virtual-8086 mode.
- System management mode (SMM).
- As a protected-mode task, when the code, data, and stack segments for the task are all configured as a 16-bit segments.
- By integrating 16-bit and 32-bit segments into a single protected-mode task.
- By integrating 16-bit operations into 32-bit code segments.

Real-address mode, virtual-8086 mode, and SMM are native 16-bit modes. A legacy program assembled and/or compiled to run on an Intel 8086 or Intel 286 processor should run in real-address mode or virtual-8086 mode without modification. Sixteen-bit program modules can also be written to run in real-address mode for handling system initialization or to run in SMM for handling system management functions. See Chapter 20, "8086 Emulation," for detailed information on real-address mode and virtual-8086 mode; see Chapter 34, "System Management Mode," for information on SMM.

This chapter describes how to integrate 16-bit program modules with 32-bit program modules when operating in protected mode and how to mix 16-bit and 32-bit code within 32-bit code segments.

## 21.1 DEFINING 16-BIT AND 32-BIT PROGRAM MODULES

The following IA-32 architecture mechanisms are used to distinguish between and support 16-bit and 32-bit segments and operations:

- The D (default operand and address size) flag in code-segment descriptors.
- The B (default stack size) flag in stack-segment descriptors.
- 16-bit and 32-bit call gates, interrupt gates, and trap gates.
- Operand-size and address-size instruction prefixes.
- 16-bit and 32-bit general-purpose registers.

The D flag in a code-segment descriptor determines the default operand-size and address-size for the instructions of a code segment. (In real-address mode and virtual-8086 mode, which do not use segment descriptors, the default is 16 bits.) A code segment with its D flag set is a 32-bit segment; a code segment with its D flag clear is a 16-bit segment.

The B flag in the stack-segment descriptor specifies the size of stack pointer (the 32-bit ESP register or the 16-bit SP register) used by the processor for implicit stack references. The B flag for all data descriptors also controls upper address range for expand down segments.

When transferring program control to another code segment through a call gate, interrupt gate, or trap gate, the operand size used during the transfer is determined by the type of gate used (16-bit or 32-bit), (not by the D-flag or prefix of the transfer instruction). The gate type determines how return information is saved on the stack (or stacks).

For most efficient and trouble-free operation of the processor, 32-bit programs or tasks should have the D flag in the code-segment descriptor and the B flag in the stack-segment descriptor set, and 16-bit programs or tasks should have these flags clear. Program control transfers from 16-bit segments to 32-bit segments (and vice versa) are handled most efficiently through call, interrupt, or trap gates.

Instruction prefixes can be used to override the default operand size and address size of a code segment. These prefixes can be used in real-address mode as well as in protected mode and virtual-8086 mode. An operand-size or address-size prefix only changes the size for the duration of the instruction.

## 21.2 MIXING 16-BIT AND 32-BIT OPERATIONS WITHIN A CODE SEGMENT

The following two instruction prefixes allow mixing of 32-bit and 16-bit operations within one segment:

- The operand-size prefix (66H)
- The address-size prefix (67H)

These prefixes reverse the default size selected by the D flag in the code-segment descriptor. For example, the processor can interpret the (MOV *mem*, *reg*) instruction in any of four ways:

- In a 32-bit code segment:
  - — Moves 32 bits from a 32-bit register to memory using a 32-bit effective address.
  - — If preceded by an operand-size prefix, moves 16 bits from a 16-bit register to memory using a 32-bit effective address.
  - — If preceded by an address-size prefix, moves 32 bits from a 32-bit register to memory using a 16-bit effective address.
  - — If preceded by both an address-size prefix and an operand-size prefix, moves 16 bits from a 16-bit register to memory using a 16-bit effective address.
- In a 16-bit code segment:
  - — Moves 16 bits from a 16-bit register to memory using a 16-bit effective address.
  - — If preceded by an operand-size prefix, moves 32 bits from a 32-bit register to memory using a 16-bit effective address.
  - — If preceded by an address-size prefix, moves 16 bits from a 16-bit register to memory using a 32-bit effective address.
  - — If preceded by both an address-size prefix and an operand-size prefix, moves 32 bits from a 32-bit register to memory using a 32-bit effective address.

The previous examples show that any instruction can generate any combination of operand size and address size regardless of whether the instruction is in a 16- or 32-bit segment. The choice of the 16- or 32-bit default for a code segment is normally based on the following criteria:

- **Performance** — Always use 32-bit code segments when possible. They run much faster than 16-bit code segments on P6 family processors, and somewhat faster on earlier IA-32 processors.
- **The operating system the code segment will be running on** — If the operating system is a 16-bit operating system, it may not support 32-bit program modules.
- **Mode of operation** — If the code segment is being designed to run in real-address mode, virtual-8086 mode, or SMM, it must be a 16-bit code segment.

- **Backward compatibility to earlier IA-32 processors** — If a code segment must be able to run on an Intel 8086 or Intel 286 processor, it must be a 16-bit code segment.

## 21.3 SHARING DATA AMONG MIXED-SIZE CODE SEGMENTS

Data segments can be accessed from both 16-bit and 32-bit code segments. When a data segment that is larger than 64 KBytes is to be shared among 16- and 32-bit code segments, the data that is to be accessed from the 16-bit code segments must be located within the first 64 KBytes of the data segment. The reason for this is that 16-bit pointers by definition can only point to the first 64 KBytes of a segment.

A stack that spans less than 64 KBytes can be shared by both 16- and 32-bit code segments. This class of stacks includes:

- Stacks in expand-up segments with the G (granularity) and B (big) flags in the stack-segment descriptor clear.
- Stacks in expand-down segments with the G and B flags clear.
- Stacks in expand-up segments with the G flag set and the B flag clear and where the stack is contained completely within the lower 64 KBytes. (Offsets greater than FFFFH can be used for data, other than the stack, which is not shared.)

See Section 3.4.5, "Segment Descriptors," for a description of the G and B flags and the expand-down stack type.

The B flag cannot, in general, be used to change the size of stack used by a 16-bit code segment. This flag controls the size of the stack pointer only for implicit stack references such as those caused by interrupts, exceptions, and the PUSH, POP, CALL, and RET instructions. It does not control explicit stack references, such as accesses to parameters or local variables. A 16-bit code segment can use a 32-bit stack only if the code is modified so that all explicit references to the stack are preceded by the 32-bit address-size prefix, causing those references to use 32-bit addressing and explicit writes to the stack pointer are preceded by a 32-bit operand-size prefix.

In 32-bit, expand-down segments, all offsets may be greater than 64 KBytes; therefore, 16-bit code cannot use this kind of stack segment unless the code segment is modified to use 32-bit addressing.

## 21.4 TRANSFERRING CONTROL AMONG MIXED-SIZE CODE SEGMENTS

There are three ways for a procedure in a 16-bit code segment to safely make a call to a 32-bit code segment:

- Make the call through a 32-bit call gate.
- Make a 16-bit call to a 32-bit interface procedure. The interface procedure then makes a 32-bit call to the intended destination.
- Modify the 16-bit procedure, inserting an operand-size prefix before the call, to change it to a 32-bit call.

Likewise, there are three ways for procedure in a 32-bit code segment to safely make a call to a 16-bit code segment:

- Make the call through a 16-bit call gate. Here, the EIP value at the CALL instruction cannot exceed FFFFH.
- Make a 32-bit call to a 16-bit interface procedure. The interface procedure then makes a 16-bit call to the intended destination.
- Modify the 32-bit procedure, inserting an operand-size prefix before the call, changing it to a 16-bit call. Be certain that the return offset does not exceed FFFFH.

These methods of transferring program control overcome the following architectural limitations imposed on calls between 16-bit and 32-bit code segments:

- Pointers from 16-bit code segments (which by default can only be 16 bits) cannot be used to address data or code located beyond FFFFH in a 32-bit segment.
- The operand-size attributes for a CALL and its companion RETURN instruction must be the same to maintain stack coherency. This is also true for implicit calls to interrupt and exception handlers and their companion IRET instructions.
- A 32-bit parameters (particularly a pointer parameter) greater than FFFFH cannot be squeezed into a 16-bit parameter location on a stack.

- The size of the stack pointer (SP or ESP) changes when switching between 16-bit and 32-bit code segments.

These limitations are discussed in greater detail in the following sections.

### 21.4.1 Code-Segment Pointer Size

For control-transfer instructions that use a pointer to identify the next instruction (that is, those that do not use gates), the operand-size attribute determines the size of the offset portion of the pointer. The implications of this rule are as follows:

- A JMP, CALL, or RET instruction from a 32-bit segment to a 16-bit segment is always possible using a 32-bit operand size, providing the 32-bit pointer does not exceed FFFFH.
- A JMP, CALL, or RET instruction from a 16-bit segment to a 32-bit segment cannot address a destination greater than FFFFH, unless the instruction is given an operand-size prefix.

See Section 21.4.5, “Writing Interface Procedures,” for an interface procedure that can transfer program control from 16-bit segments to destinations in 32-bit segments beyond FFFFH.

### 21.4.2 Stack Management for Control Transfer

Because the stack is managed differently for 16-bit procedure calls than for 32-bit calls, the operand-size attribute of the RET instruction must match that of the CALL instruction (see Figure 21-1). On a 16-bit call, the processor pushes the contents of the 16-bit IP register and (for calls between privilege levels) the 16-bit SP register. The matching RET instruction must also use a 16-bit operand size to pop these 16-bit values from the stack into the 16-bit registers.

A 32-bit CALL instruction pushes the contents of the 32-bit EIP register and (for inter-privilege-level calls) the 32-bit ESP register. Here, the matching RET instruction must use a 32-bit operand size to pop these 32-bit values from the stack into the 32-bit registers. If the two parts of a CALL/RET instruction pair do not have matching operand sizes, the stack will not be managed correctly and the values of the instruction pointer and stack pointer will not be restored to correct values.

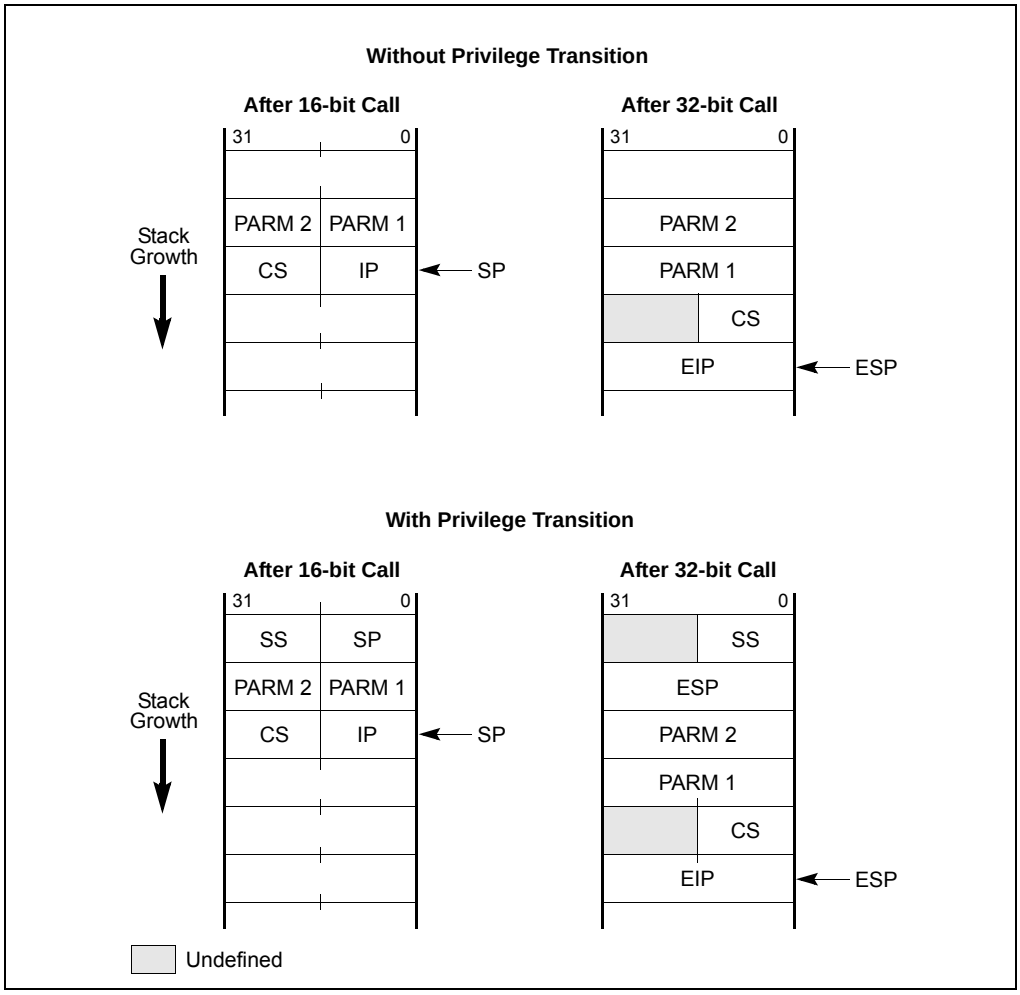

Figure 21-1. Stack after Far 16- and 32-Bit Calls

While executing 32-bit code, if a call is made to a 16-bit code segment which is at the same or a more privileged level (that is, the DPL of the called code segment is less than or equal to the CPL of the calling code segment) through a 16-bit call gate, then the upper 16-bits of the ESP register may be unreliable upon returning to the 32-bit code segment (that is, after executing a RET in the 16-bit code segment).

When the CALL instruction and its matching RET instruction are in code segments that have D flags with the same values (that is, both are 32-bit code segments or both are 16-bit code segments), the default settings may be used. When the CALL instruction and its matching RET instruction are in segments which have different D-flag settings, an operand-size prefix must be used.

### 21.4.2.1 Controlling the Operand-Size Attribute For a Call

Three things can determine the operand-size of a call:

- The D flag in the segment descriptor for the calling code segment.
- An operand-size instruction prefix.
- The type of call gate (16-bit or 32-bit), if a call is made through a call gate.

When a call is made with a pointer (rather than a call gate), the D flag for the calling code segment determines the operand-size for the CALL instruction. This operand-size attribute can be overridden by prepending an operand-size prefix to the CALL instruction. So, for example, if the D flag for a code segment is set for 16 bits and the operand-size prefix is used with a CALL instruction, the processor will cause the information stored on the stack to

be stored in 32-bit format. If the call is to a 32-bit code segment, the instructions in that code segment will be able to read the stack coherently. Also, a RET instruction from the 32-bit code segment without an operand-size prefix will maintain stack coherency with the 16-bit code segment being returned to.

When a CALL instruction references a call-gate descriptor, the type of call is determined by the type of call gate (16-bit or 32-bit). The offset to the destination in the code segment being called is taken from the gate descriptor; therefore, if a 32-bit call gate is used, a procedure in a 16-bit code segment can call a procedure located more than 64 KBytes from the base of a 32-bit code segment, because a 32-bit call gate uses a 32-bit offset.

Note that regardless of the operand size of the call and how it is determined, the size of the stack pointer used (SP or ESP) is always controlled by the B flag in the stack-segment descriptor currently in use (that is, when B is clear, SP is used, and when B is set, ESP is used).

An unmodified 16-bit code segment that has run successfully on an 8086 processor or in real-mode on a later IA-32 architecture processor will have its D flag clear and will not use operand-size override prefixes. As a result, all CALL instructions in this code segment will use the 16-bit operand-size attribute. Procedures in these code segments can be modified to safely call procedures to 32-bit code segments in either of two ways:

- Relink the CALL instruction to point to 32-bit call gates (see Section 21.4.2.2, "Passing Parameters With a Gate").
- Add a 32-bit operand-size prefix to each CALL instruction.

#### 21.4.2.2 Passing Parameters With a Gate

When referencing 32-bit gates with 16-bit procedures, it is important to consider the number of parameters passed in each procedure call. The count field of the gate descriptor specifies the size of the parameter string to copy from the current stack to the stack of a more privileged (numerically lower privilege level) procedure. The count field of a 16-bit gate specifies the number of 16-bit words to be copied, whereas the count field of a 32-bit gate specifies the number of 32-bit doublewords to be copied. The count field for a 32-bit gate must thus be half the size of the number of words being placed on the stack by a 16-bit procedure. Also, the 16-bit procedure must use an even number of words as parameters.

### 21.4.3 Interrupt Control Transfers

A program-control transfer caused by an exception or interrupt is always carried out through an interrupt or trap gate (located in the IDT). Here, the type of the gate (16-bit or 32-bit) determines the operand-size attribute used in the implicit call to the exception or interrupt handler procedure in another code segment.

A 32-bit interrupt or trap gate provides a safe interface to a 32-bit exception or interrupt handler when the exception or interrupt occurs in either a 32-bit or a 16-bit code segment. It is sometimes impractical, however, to place exception or interrupt handlers in 16-bit code segments, because only 16-bit return addresses are saved on the stack. If an exception or interrupt occurs in a 32-bit code segment when the EIP was greater than FFFFH, the 16-bit handler procedure cannot provide the correct return address.

### 21.4.4 Parameter Translation

When segment offsets or pointers (which contain segment offsets) are passed as parameters between 16-bit and 32-bit procedures, some translation is required. If a 32-bit procedure passes a pointer to data located beyond 64 KBytes to a 16-bit procedure, the 16-bit procedure cannot use it. Except for this limitation, interface code can perform any format conversion between 32-bit and 16-bit pointers that may be needed.

Parameters passed by value between 32-bit and 16-bit code also may require translation between 32-bit and 16-bit formats. The form of the translation is application-dependent.

### 21.4.5 Writing Interface Procedures

Placing interface code between 32-bit and 16-bit procedures can be the solution to the following interface problems:

- Allowing procedures in 16-bit code segments to call procedures with offsets greater than FFFFH in 32-bit code segments.
- Matching operand-size attributes between companion CALL and RET instructions.
- Translating parameters (data), including managing parameter strings with a variable count or an odd number of 16-bit words.
- The possible invalidation of the upper bits of the ESP register.

The interface procedure is simplified where these rules are followed.

1. The interface procedure must reside in a 32-bit code segment (the D flag for the code-segment descriptor is set).
2. All procedures that may be called by 16-bit procedures must have offsets not greater than FFFFH.
3. All return addresses saved by 16-bit procedures must have offsets not greater than FFFFH.

The interface procedure becomes more complex if any of these rules are violated. For example, if a 16-bit procedure calls a 32-bit procedure with an entry point beyond FFFFH, the interface procedure will need to provide the offset to the entry point. The mapping between 16- and 32-bit addresses is only performed automatically when a call gate is used, because the gate descriptor for a call gate contains a 32-bit address. When a call gate is not used, the interface code must provide the 32-bit address.

The structure of the interface procedure depends on the types of calls it is going to support, as follows:

- **Calls from 16-bit procedures to 32-bit procedures** — Calls to the interface procedure from a 16-bit code segment are made with 16-bit CALL instructions (by default, because the D flag for the calling code-segment descriptor is clear), and 16-bit operand-size prefixes are used with RET instructions to return from the interface procedure to the calling procedure. Calls from the interface procedure to 32-bit procedures are performed with 32-bit CALL instructions (by default, because the D flag for the interface procedure's code segment is set), and returns from the called procedures to the interface procedure are performed with 32-bit RET instructions (also by default).
- **Calls from 32-bit procedures to 16-bit procedures** — Calls to the interface procedure from a 32-bit code segment are made with 32-bit CALL instructions (by default), and returns to the calling procedure from the interface procedure are made with 32-bit RET instructions (also by default). Calls from the interface procedure to 16-bit procedures require the CALL instructions to have the operand-size prefixes, and returns from the called procedures to the interface procedure are performed with 16-bit RET instructions (by default).

# CHAPTER 22
# ARCHITECTURE COMPATIBILITY

Intel 64 and IA-32 processors are binary compatible. Compatibility means that, within limited constraints, programs that execute on previous generations of processors will produce identical results when executed on later processors. The compatibility constraints and any implementation differences between the Intel 64 and IA-32 processors are described in this chapter.

Each new processor has enhanced the software visible architecture from that found in earlier Intel 64 and IA-32 processors. Those enhancements have been defined with consideration for compatibility with previous and future processors. This chapter also summarizes the compatibility considerations for those extensions.

## 22.1 PROCESSOR FAMILIES AND CATEGORIES

IA-32 processors are referred to in several different ways in this chapter, depending on the type of compatibility information being related, as described in the following:

- **IA-32 Processors** — All the Intel processors based on the Intel IA-32 Architecture, which include the 8086/88, Intel 286, Intel386, Intel486, Pentium, Pentium Pro, Pentium II, Pentium III, Pentium 4, and Intel Xeon processors.
- **32-bit Processors** — All the IA-32 processors that use a 32-bit architecture, which include the Intel386, Intel486, Pentium, Pentium Pro, Pentium II, Pentium III, Pentium 4, and Intel Xeon processors.
- **16-bit Processors** — All the IA-32 processors that use a 16-bit architecture, which include the 8086/88 and Intel 286 processors.
- **P6 Family Processors** — All the IA-32 processors that are based on the P6 microarchitecture, which include the Pentium Pro, Pentium II, and Pentium III processors.
- **Pentium® 4 Processors** — A family of IA-32 and Intel 64 processors that are based on the Intel NetBurst® microarchitecture.
- **Intel® Pentium® M Processors** — A family of IA-32 processors that are based on the Intel Pentium M processor microarchitecture.
- **Intel® Core™ Duo and Solo Processors** — Families of IA-32 processors that are based on an improved Intel Pentium M processor microarchitecture.
- **Intel® Xeon® Processors** — A family of IA-32 and Intel 64 processors that are based on the Intel NetBurst microarchitecture. This family includes the Intel Xeon processor and the Intel Xeon processor MP based on the Intel NetBurst microarchitecture. Intel Xeon processors 3000, 3100, 3200, 3300, 3200, 5100, 5200, 5300, 5400, 7200, 7300 series are based on Intel Core microarchitectures and support Intel 64 architecture.
- **Pentium® D Processors** — A family of dual-core Intel 64 processors that provides two processor cores in a physical package. Each core is based on the Intel NetBurst microarchitecture.
- **Pentium® Processor Extreme Editions** — A family of dual-core Intel 64 processors that provides two processor cores in a physical package. Each core is based on the Intel NetBurst microarchitecture and supports Intel Hyper-Threading Technology.
- **Intel® Core™ 2 Processor family**— A family of Intel 64 processors that are based on the Intel Core microarchitecture. Intel Pentium Dual-Core processors are also based on the Intel Core microarchitecture.
- **Intel® Atom™ Processors** — A family of IA-32 and Intel 64 processors that are based on the Intel Atom microarchitecture.

## 22.2 RESERVED BITS

Throughout this manual, certain bits are marked as reserved in many register and memory layout descriptions. When bits are marked as undefined or reserved, it is essential for compatibility with future processors that software

treat these bits as having a future, though unknown effect. Software should follow these guidelines in dealing with reserved bits:

- Do not depend on the states of any reserved bits when testing the values of registers or memory locations that contain such bits. Mask out the reserved bits before testing.
- Do not depend on the states of any reserved bits when storing them to memory or to a register.
- Do not depend on the ability to retain information written into any reserved bits.
- When loading a register, always load the reserved bits with the values indicated in the documentation, if any, or reload them with values previously read from the same register.

Software written for existing IA-32 processor that handles reserved bits correctly will port to future IA-32 processors without generating protection exceptions.

## 22.3 ENABLING NEW FUNCTIONS AND MODES

Most of the new control functions defined for the P6 family and Pentium processors are enabled by new mode flags in the control registers (primarily register CR4). This register is undefined for IA-32 processors earlier than the Pentium processor. Attempting to access this register with an Intel486 or earlier IA-32 processor results in an invalid-opcode exception (#UD). Consequently, programs that execute correctly on the Intel486 or earlier IA-32 processor cannot erroneously enable these functions. Attempting to set a reserved bit in register CR4 to a value other than its original value results in a general-protection exception (#GP). So, programs that execute on the P6 family and Pentium processors cannot erroneously enable functions that may be implemented in future IA-32 processors.

The P6 family and Pentium processors do not check for attempts to set reserved bits in model-specific registers; however these bits may be checked on more recent processors. It is the obligation of the software writer to enforce this discipline. These reserved bits may be used in future Intel processors.

## 22.4 DETECTING THE PRESENCE OF NEW FEATURES THROUGH SOFTWARE

Software can check for the presence of new architectural features and extensions in either of two ways:

1. Test for the presence of the feature or extension. Software can test for the presence of new flags in the EFLAGS register and control registers. If these flags are reserved (meaning not present in the processor executing the test), an exception is generated. Likewise, software can attempt to execute a new instruction, which results in an invalid-opcode exception (#UD) being generated if it is not supported.
2. Execute the CPUID instruction. The CPUID instruction (added to the IA-32 in the Pentium processor) indicates the presence of new features directly.

See Chapter 17, "Processor Identification and Feature Determination," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, for detailed information on detecting new processor features and extensions.

## 22.5 INTEL MMX TECHNOLOGY

The Pentium processor with MMX technology introduced the MMX technology and a set of MMX instructions to the IA-32. The MMX instructions are described in Chapter 9, "Programming with Intel® MMX™ Technology," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*. The MMX technology and MMX instructions are also included in the Pentium II, Pentium III, Pentium 4, and Intel Xeon processors.

## 22.6 STREAMING SIMD EXTENSIONS (SSE)

The Streaming SIMD Extensions (SSE) were introduced in the Pentium III processor. The SSE extensions consist of a new set of instructions and a new set of registers. The new registers include the eight 128-bit XMM registers and the 32-bit MXCSR control and status register. These instructions and registers are designed to allow SIMD computations to be made on single-precision floating-point numbers. Several of these new instructions also operate in the MMX registers. SSE instructions and registers are described in Section 10, "Programming with Streaming SIMD Extensions (SSE)," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*.

## 22.7 STREAMING SIMD EXTENSIONS 2 (SSE2)

The Streaming SIMD Extensions 2 (SSE2) were introduced in the Pentium 4 and Intel Xeon processors. They consist of a new set of instructions that operate on the XMM and MXCSR registers and perform SIMD operations on double-precision floating-point values and on integer values. Several of these new instructions also operate in the MMX registers. SSE2 instructions and registers are described in Chapter 11, "Programming with Streaming SIMD Extensions 2 (SSE2)," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*.

## 22.8 STREAMING SIMD EXTENSIONS 3 (SSE3)

The Streaming SIMD Extensions 3 (SSE3) were introduced in Pentium 4 processors supporting Intel Hyper-Threading Technology and Intel Xeon processors. SSE3 extensions include 13 instructions. Ten of these 13 instructions support the single instruction multiple data (SIMD) execution model used with SSE/SSE2 extensions. One SSE3 instruction accelerates x87 style programming for conversion to integer. The remaining two instructions (MONITOR and MWAIT) accelerate synchronization of threads. SSE3 instructions are described in Chapter 12, "Programming with SSE3, SSSE3 and SSE4," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*.

## 22.9 ADDITIONAL STREAMING SIMD EXTENSIONS

The Supplemental Streaming SIMD Extensions 3 (SSSE3) were introduced in the Intel Core 2 processor and Intel Xeon processor 5100 series. Streaming SIMD Extensions 4 provided 54 new instructions introduced in 45nm Intel Xeon processors and Intel Core 2 processors. SSSE3, SSE4.1 and SSE4.2 instructions are described in Chapter 12, "Programming with SSE3, SSSE3 and SSE4," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*.

## 22.10 INTEL HYPER-THREADING TECHNOLOGY

Intel Hyper-Threading Technology provides two logical processors that can execute two separate code streams (called *threads*) concurrently by using shared resources in a single processor core or in a physical package.

This feature was introduced in the Intel Xeon processor MP and later steppings of the Intel Xeon processor, and Pentium 4 processors supporting Intel Hyper-Threading Technology. The feature is also found in the Pentium processor Extreme Edition. See also: Section 8.7, "Intel® Hyper-Threading Technology Architecture."

Intel Atom processors also support Intel Hyper-Threading Technology.

## 22.11 MULTI-CORE TECHNOLOGY

The Pentium D processor and Pentium processor Extreme Edition provide two processor cores in each physical processor package. See also: Section 8.5, "Intel® Hyper-Threading Technology and Intel® Multi-Core Technology," and Section 8.8, "Multi-Core Architecture." Intel Core 2 Duo, Intel Pentium Dual-Core processors, Intel Xeon processors 3000, 3100, 5100, 5200 series provide two processor cores in each physical processor package. Intel Core 2 Extreme, Intel Core 2 Quad processors, Intel Xeon processors 3200, 3300, 5300, 5400, 7300 series provide two processor cores in each physical processor package.

## 22.12 SPECIFIC FEATURES OF DUAL-CORE PROCESSOR

Dual-core processors may have some processor-specific features. Use CPUID feature flags to detect the availability features. Note the following:

- **CPUID Brand String** — On Pentium processor Extreme Edition, the process will report the correct brand string only after the correct microcode updates are loaded.
- **Enhanced Intel SpeedStep Technology** — This feature is supported in Pentium D processor but not in Pentium processor Extreme Edition.

## 22.13 NEW INSTRUCTIONS IN THE PENTIUM AND LATER IA-32 PROCESSORS

Table 22-1 identifies the instructions introduced into the IA-32 in the Pentium processor and later IA-32 processors.

### 22.13.1 Instructions Added Prior to the Pentium Processor

The following instructions were added in the Intel486 processor:

- BSWAP (byte swap) instruction.
- XADD (exchange and add) instruction.
- CMPXCHG (compare and exchange) instruction.
- INVD (invalidate cache) instruction.
- WBINVD (write-back and invalidate cache) instruction.
- INVLPG (invalidate TLB entry) instruction.

**Table 22-1. New Instruction in the Pentium Processor and Later IA-32 Processors**

| Instruction | CPUID Identification Bits | Introduced In |
|---|---|---|
| CMOV*cc* (conditional move) | EDX, Bit 15 | Pentium Pro processor |
| FCMOV*cc* (floating-point conditional move) | EDX, Bits 0 and 15 | |
| FCOMI (floating-point compare and set EFLAGS) | EDX, Bits 0 and 15 | |
| RDPMC (read performance monitoring counters) | EAX, Bits 8-11, set to 6H; see Note 1 | |
| UD2 (undefined) | EAX, Bits 8-11, set to 6H | |
| CMPXCHG8B (compare and exchange 8 bytes) | EDX, Bit 8 | Pentium processor |
| CPUID (CPU identification) | None; see Note 2 | |
| RDTSC (read time-stamp counter) | EDX, Bit 4 | |
| RDMSR (read model-specific register) | EDX, Bit 5 | |
| WRMSR (write model-specific register) | EDX, Bit 5 | |
| MMX Instructions | EDX, Bit 23 | |

Table 22-1. New Instruction in the Pentium Processor and Later IA-32 Processors (Contd.)

| Instruction | CPUID Identification Bits | Introduced In |
|---|---|---|

NOTES:

1. The RDPMC instruction was introduced in the P6 family of processors and added to later model Pentium processors. This instruction is model specific in nature and not architectural.
2. The CPUID instruction is available in all Pentium and P6 family processors and in later models of the Intel486 processors. The ability to set and clear the ID flag (bit 21) in the EFLAGS register indicates the availability of the CPUID instruction.

The following instructions were added in the Intel386 processor:

- LSS, LFS, and LGS (load SS, FS, and GS registers).
- Long-displacement conditional jumps.
- Single-bit instructions.
- Bit scan instructions.
- Double-shift instructions.
- Byte set on condition instruction.
- Move with sign/zero extension.
- Generalized multiply instruction.
- MOV to and from control registers.
- MOV to and from test registers (now obsolete).
- MOV to and from debug registers.
- RSM (resume from SMM). This instruction was introduced in the Intel386 SL and Intel486 SL processors.

The following instructions were added in the Intel 387 math coprocessor:

- FPREM1.
- FUCOM, FUCOMP, and FUCOMPP.

## 22.14 OBSOLETE INSTRUCTIONS

The MOV to and from test registers instructions were removed from the Pentium processor and future IA-32 processors. Execution of these instructions generates an invalid-opcode exception (#UD).

## 22.15 UNDEFINED OPCODES

All new instructions defined for IA-32 processors use binary encodings that were reserved on earlier-generation processors. Attempting to execute a reserved opcode always results in an invalid-opcode (#UD) exception being generated. Consequently, programs that execute correctly on earlier-generation processors cannot erroneously execute these instructions and thereby produce unexpected results when executed on later IA-32 processors.

## 22.16 NEW FLAGS IN THE EFLAGS REGISTER

The section titled "EFLAGS Register" in Chapter 3, "Basic Execution Environment," of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, shows the configuration of flags in the EFLAGS register for the P6 family processors. No new flags have been added to this register in the P6 family processors. The flags added to this register in the Pentium and Intel486 processors are described in the following sections.

The following flags were added to the EFLAGS register in the Pentium processor:

- VIF (virtual interrupt flag), bit 19.
- VIP (virtual interrupt pending), bit 20.

- ID (identification flag), bit 21.

The AC flag (bit 18) was added to the EFLAGS register in the Intel486 processor.

### 22.16.1 Using EFLAGS Flags to Distinguish Between 32-Bit IA-32 Processors

The following bits in the EFLAGS register that can be used to differentiate between the 32-bit IA-32 processors:

- Bit 18 (the AC flag) can be used to distinguish an Intel386 processor from the P6 family, Pentium, and Intel486 processors. Since it is not implemented on the Intel386 processor, it will always be clear.
- Bit 21 (the ID flag) indicates whether an application can execute the CPUID instruction. The ability to set and clear this bit indicates that the processor is a P6 family or Pentium processor. The CPUID instruction can then be used to determine which processor.
- Bits 19 (the VIF flag) and 20 (the VIP flag) will always be zero on processors that do not support virtual mode extensions, which includes all 32-bit processors prior to the Pentium processor.

See Chapter 17, "Processor Identification and Feature Determination," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, for more information on identifying processors.

## 22.17 STACK OPERATIONS

This section identifies the differences in stack implementation between the various IA-32 processors.

### 22.17.1 PUSH SP

The P6 family, Pentium, Intel486, Intel386, and Intel 286 processors push a different value on the stack for a PUSH SP instruction than the 8086 processor. The 32-bit processors push the value of the SP register before it is decremented as part of the push operation; the 8086 processor pushes the value of the SP register after it is decremented. If the value pushed is important, replace PUSH SP instructions with the following three instructions:

```
PUSH BP
MOV  BP, SP
XCHG BP, [BP]
```

This code functions as the 8086 processor PUSH SP instruction on the P6 family, Pentium, Intel486, Intel386, and Intel 286 processors.

### 22.17.2 EFLAGS Pushed on the Stack

The setting of the stored values of bits 12 through 15 (which includes the IOPL field and the NT flag) in the EFLAGS register by the PUSHF instruction, by interrupts, and by exceptions is different with the 32-bit IA-32 processors than with the 8086 and Intel 286 processors. The differences are as follows:

- 8086 processor—bits 12 through 15 are always set.
- Intel 286 processor—bits 12 through 15 are always cleared in real-address mode.
- 32-bit processors in real-address mode—bit 15 (reserved) is always cleared, and bits 12 through 14 have the last value loaded into them.

## 22.18 X87 FPU

This section addresses the issues that must be faced when porting floating-point software designed to run on earlier IA-32 processors and math coprocessors to a Pentium 4, Intel Xeon, P6 family, or Pentium processor with integrated x87 FPU. To software, a Pentium 4, Intel Xeon, or P6 family processor looks very much like a Pentium processor. Floating-point software which runs on a Pentium or Intel486 DX processor, or on an Intel486 SX

processor/Intel 487 SX math coprocessor system or an Intel386 processor/Intel 387 math coprocessor system, will run with at most minor modifications on a Pentium 4, Intel Xeon, or P6 family processor. To port code directly from an Intel 286 processor/Intel 287 math coprocessor system or an Intel 8086 processor/8087 math coprocessor system to a Pentium 4, Intel Xeon, P6 family, or Pentium processor, certain additional issues must be addressed.

In the following sections, the term "32-bit x87 FPUs" refers to the P6 family, Pentium, and Intel486 DX processors, and to the Intel 487 SX and Intel 387 math coprocessors; the term "16-bit IA-32 math coprocessors" refers to the Intel 287 and 8087 math coprocessors.

## 22.18.1 Control Register CR0 Flags

The ET, NE, and MP flags in control register CR0 control the interface between the integer unit of an IA-32 processor and either its internal x87 FPU or an external math coprocessor. The effect of these flags in the various IA-32 processors are described in the following paragraphs.

The ET (extension type) flag (bit 4 of the CR0 register) is used in the Intel386 processor to indicate whether the math coprocessor in the system is an Intel 287 math coprocessor (flag is clear) or an Intel 387 DX math coprocessor (flag is set). This bit is hardwired to 1 in the P6 family, Pentium, and Intel486 processors.

The NE (Numeric Exception) flag (bit 5 of the CR0 register) is used in the P6 family, Pentium, and Intel486 processors to determine whether unmasked floating-point exceptions are reported internally through interrupt vector 16 (flag is set) or externally through an external interrupt (flag is clear). On a hardware reset, the NE flag is initialized to 0, so software using the automatic internal error-reporting mechanism must set this flag to 1. This flag is nonexistent on the Intel386 processor.

As on the Intel 286 and Intel386 processors, the MP (monitor coprocessor) flag (bit 1 of register CR0) determines whether the WAIT/FWAIT instructions or waiting-type floating-point instructions trap when the context of the x87 FPU is different from that of the currently-executing task. If the MP and TS flag are set, then a WAIT/FWAIT instruction and waiting instructions will cause a device-not-available exception (interrupt vector 7). The MP flag is used on the Intel 286 and Intel386 processors to support the use of a WAIT/FWAIT instruction to wait on a device other than a math coprocessor. The device reports its status through the BUSY# pin. Since the P6 family, Pentium, and Intel486 processors do not have such a pin, the MP flag has no relevant use and should be set to 1 for normal operation.

## 22.18.2 x87 FPU Status Word

This section identifies differences to the x87 FPU status word for the different IA-32 processors and math coprocessors, the reason for the differences, and their impact on software.

### 22.18.2.1 Condition Code Flags (C0 through C3)

The following information pertains to differences in the use of the condition code flags (C0 through C3) located in bits 8, 9, 10, and 14 of the x87 FPU status word.

After execution of an FINIT instruction or a hardware reset on a 32-bit x87 FPU, the condition code flags are set to 0. The same operations on a 16-bit IA-32 math coprocessor leave these flags intact (they contain their prior value). This difference in operation has no impact on software and provides a consistent state after reset.

Transcendental instruction results in the core range of the P6 family and Pentium processors may differ from the Intel486 DX processor and Intel 487 SX math coprocessor by 2 to 3 units in the last place (ulps)—(see "Transcendental Instruction Accuracy" in Chapter 8, "Programming with the x87 FPU," of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*). As a result, the value saved in the C1 flag may also differ.

After an incomplete FPREM/FPREM1 instruction, the C0, C1, and C3 flags are set to 0 on the 32-bit x87 FPUs. After the same operation on a 16-bit IA-32 math coprocessor, these flags are left intact.

On the 32-bit x87 FPUs, the C2 flag serves as an incomplete flag for the FTAN instruction. On the 16-bit IA-32 math coprocessors, the C2 flag is undefined for the FPTAN instruction. This difference has no impact on software, because Intel 287 or 8087 programs do not check C2 after an FPTAN instruction. The use of this flag on later processors allows fast checking of operand range.

#### 22.18.2.2 Stack Fault Flag

When unmasked stack overflow or underflow occurs on a 32-bit x87 FPU, the IE flag (bit 0) and the SF flag (bit 6) of the x87 FPU status word are set to indicate a stack fault and condition code flag C1 is set or cleared to indicate overflow or underflow, respectively. When unmasked stack overflow or underflow occurs on a 16-bit IA-32 math coprocessor, only the IE flag is set. Bit 6 is reserved on these processors. The addition of the SF flag on a 32-bit x87 FPU has no impact on software. Existing exception handlers need not change, but may be upgraded to take advantage of the additional information.

### 22.18.3 x87 FPU Control Word

Only affine closure is supported for infinity control on a 32-bit x87 FPU. The infinity control flag (bit 12 of the x87 FPU control word) remains programmable on these processors, but has no effect. This change was made to conform to the IEEE Standard 754 for Binary Floating-Point Arithmetic. On a 16-bit IA-32 math coprocessor, both affine and projective closures are supported, as determined by the setting of bit 12. After a hardware reset, the default value of bit 12 is projective. Software that requires projective infinity arithmetic may give different results.

### 22.18.4 x87 FPU Tag Word

When loading the tag word of a 32-bit x87 FPU, using an FLDENV, FRSTOR, or FXRSTOR (Pentium III processor only) instruction, the processor examines the incoming tag and classifies the location only as empty or non-empty. Thus, tag values of 00, 01, and 10 are interpreted by the processor to indicate a non-empty location. The tag value of 11 is interpreted by the processor to indicate an empty location. Subsequent operations on a non-empty register always examine the value in the register, not the value in its tag. The FSTENV, FSAVE, and FXSAVE (Pentium III processor only) instructions examine the non-empty registers and put the correct values in the tags before storing the tag word.

The corresponding tag for a 16-bit IA-32 math coprocessor is checked before each register access to determine the class of operand in the register; the tag is updated after every change to a register so that the tag always reflects the most recent status of the register. Software can load a tag with a value that disagrees with the contents of a register (for example, the register contains a valid value, but the tag says special). Here, the 16-bit IA-32 math coprocessors honor the tag and do not examine the register.

Software written to run on a 16-bit IA-32 math coprocessor may not operate correctly on a 16-bit x87 FPU, if it uses the FLDENV, FRSTOR, or FXRSTOR instructions to change tags to values (other than to empty) that are different from actual register contents.

The encoding in the tag word for the 32-bit x87 FPUs for unsupported data formats (including pseudo-zero and unnormal) is special (10B), to comply with IEEE Standard 754. The encoding in the 16-bit IA-32 math coprocessors for pseudo-zero and unnormal is valid (00B) and the encoding for other unsupported data formats is special (10B). Code that recognizes the pseudo-zero or unnormal format as valid must therefore be changed if it is ported to a 32-bit x87 FPU.

### 22.18.5 Data Types

This section discusses the differences of data types for the various x87 FPUs and math coprocessors.

#### 22.18.5.1 NaNs

The 32-bit x87 FPUs distinguish between signaling NaNs (SNaNs) and quiet NaNs (QNaNs). These x87 FPUs only generate QNaNs and normally do not generate an exception upon encountering a QNaN. An invalid-operation exception (#I) is generated only upon encountering a SNaN, except for the FCOM, FIST, and FBSTP instructions, which also generates an invalid-operation exceptions for a QNaNs. This behavior matches IEEE Standard 754.

The 16-bit IA-32 math coprocessors only generate one kind of NaN (the equivalent of a QNaN), but the raise an invalid-operation exception upon encountering any kind of NaN.

When porting software written to run on a 16-bit IA-32 math coprocessor to a 32-bit x87 FPU, uninitialized memory locations that contain QNaNs should be changed to SNaNs to cause the x87 FPU or math coprocessor to fault when uninitialized memory locations are referenced.

### 22.18.5.2 Pseudo-zero, Pseudo-NaN, Pseudo-infinity, and Unnormal Formats

The 32-bit x87 FPUs neither generate nor support the pseudo-zero, pseudo-NaN, pseudo-infinity, and unnormal formats. Whenever they encounter them in an arithmetic operation, they raise an invalid-operation exception. The 16-bit IA-32 math coprocessors define and support special handling for these formats. Support for these formats was dropped to conform with IEEE Standard 754 for Binary Floating-Point Arithmetic.

This change should not impact software ported from 16-bit IA-32 math coprocessors to 32-bit x87 FPUs. The 32-bit x87 FPUs do not generate these formats, and therefore will not encounter them unless software explicitly loads them in the data registers. The only affect may be in how software handles the tags in the tag word (see also: Section 22.18.4, "x87 FPU Tag Word").

## 22.18.6 Floating-Point Exceptions

This section identifies the implementation differences in exception handling for floating-point instructions in the various x87 FPUs and math coprocessors.

### 22.18.6.1 Denormal Operand Exception (#D)

When the denormal operand exception is masked, the 32-bit x87 FPUs automatically normalize denormalized numbers when possible; whereas, the 16-bit IA-32 math coprocessors return a denormal result. A program written to run on a 16-bit IA-32 math coprocessor that uses the denormal exception solely to normalize denormalized operands is redundant when run on the 32-bit x87 FPUs. If such a program is run on 32-bit x87 FPUs, performance can be improved by masking the denormal exception. Floating-point programs run faster when the FPU performs normalization of denormalized operands.

The denormal operand exception is not raised for transcendental instructions and the FXTRACT instruction on the 16-bit IA-32 math coprocessors. This exception is raised for these instructions on the 32-bit x87 FPUs. The exception handlers ported to these latter processors need to be changed only if the handlers gives special treatment to different opcodes.

### 22.18.6.2 Numeric Overflow Exception (#O)

On the 32-bit x87 FPUs, when the numeric overflow exception is masked and the rounding mode is set to chop (toward 0), the result is the largest positive or smallest negative number. The 16-bit IA-32 math coprocessors do not signal the overflow exception when the masked response is not ∞; that is, they signal overflow only when the rounding control is not set to round to 0. If rounding is set to chop (toward 0), the result is positive or negative ∞. Under the most common rounding modes, this difference has no impact on existing software.

If rounding is toward 0 (chop), a program on a 32-bit x87 FPU produces, under overflow conditions, a result that is different in the least significant bit of the significand, compared to the result on a 16-bit IA-32 math coprocessor. The reason for this difference is IEEE Standard 754 compatibility.

When the overflow exception is not masked, the precision exception is flagged on the 32-bit x87 FPUs. When the result is stored in the stack, the significand is rounded according to the precision control (PC) field of the FPU control word or according to the opcode. On the 16-bit IA-32 math coprocessors, the precision exception is not flagged and the significand is not rounded. The impact on existing software is that if the result is stored on the stack, a program running on a 32-bit x87 FPU produces a different result under overflow conditions than on a 16-bit IA-32 math coprocessor. The difference is apparent only to the exception handler. This difference is for IEEE Standard 754 compatibility.

### 22.18.6.3 Numeric Underflow Exception (#U)

When the underflow exception is masked on the 32-bit x87 FPUs, the underflow exception is signaled when both the result is tiny and denormalization results in a loss of accuracy. When the underflow exception is unmasked and the instruction is supposed to store the result on the stack, the significand is rounded to the appropriate precision (according to the PC flag in the FPU control word, for those instructions controlled by PC, otherwise to extended precision), after adjusting the exponent.

When the underflow exception is masked on the 16-bit IA-32 math coprocessors and rounding is toward 0, the underflow exception flag is raised on a tiny result, regardless of loss of accuracy. When the underflow exception is not masked and the destination is the stack, the significand is not rounded, but instead is left as is.

When the underflow exception is masked, this difference has no impact on existing software. The underflow exception occurs less often when rounding is toward 0.

When the underflow exception not masked. A program running on a 32-bit x87 FPU produces a different result during underflow conditions than on a 16-bit IA-32 math coprocessor if the result is stored on the stack. The difference is only in the least significant bit of the significand and is apparent only to the exception handler.

### 22.18.6.4 Exception Precedence

There is no difference in the precedence of the denormal-operand exception on the 32-bit x87 FPUs, whether it be masked or not. When the denormal-operand exception is not masked on the 16-bit IA-32 math coprocessors, it takes precedence over all other exceptions. This difference causes no impact on existing software, but some unneeded normalization of denormalized operands is prevented on the Intel486 processor and Intel 387 math coprocessor.

### 22.18.6.5 CS and EIP For FPU Exceptions

On the Intel 32-bit x87 FPUs, the values from the CS and EIP registers saved for floating-point exceptions point to any prefixes that come before the floating-point instruction. On the 8087 math coprocessor, the saved CS and IP registers points to the floating-point instruction.

### 22.18.6.6 FPU Error Signals

The floating-point error signals to the P6 family, Pentium, and Intel486 processors do not pass through an interrupt controller; an INT# signal from an Intel 387, Intel 287 or 8087 math coprocessors does. If an 8086 processor uses another exception for the 8087 interrupt, both exception vectors should call the floating-point-error exception handler. Some instructions in a floating-point-error exception handler may need to be deleted if they use the interrupt controller. The P6 family, Pentium, and Intel486 processors have signals that, with the addition of external logic, support reporting for emulation of the interrupt mechanism used in many personal computers.

On the P6 family, Pentium, and Intel486 processors, an undefined floating-point opcode will cause an invalid-opcode exception (#UD, interrupt vector 6). Undefined floating-point opcodes, like legal floating-point opcodes, cause a device not available exception (#NM, interrupt vector 7) when either the TS or EM flag in control register CR0 is set. The P6 family, Pentium, and Intel486 processors do not check for floating-point error conditions on encountering an undefined floating-point opcode.

### 22.18.6.7 Assertion of the FERR# Pin

When using the MS-DOS compatibility mode for handing floating-point exceptions, the FERR# pin must be connected to an input to an external interrupt controller. An external interrupt is then generated when the FERR# output drives the input to the interrupt controller and the interrupt controller in turn drives the INTR pin on the processor.

For the P6 family and Intel386 processors, an unmasked floating-point exception always causes the FERR# pin to be asserted upon completion of the instruction that caused the exception. For the Pentium and Intel486 processors, an unmasked floating-point exception may cause the FERR# pin to be asserted either at the end of the instruction causing the exception or immediately before execution of the next floating-point instruction. (Note that the next floating-point instruction would not be executed until the pending unmasked exception has been handled.)

See Appendix D, "Guidelines for Writing x87 FPU Extension Handlers," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, for a complete description of the required mechanism for handling floating-point exceptions using the MS-DOS compatibility mode.

Using FERR# and IGNNE# to handle floating-point exception is deprecated by modern operating systems; this approach also limits newer processors to operate with one logical processor active.

### 22.18.6.8 Invalid Operation Exception On Denormals

An invalid-operation exception is not generated on the 32-bit x87 FPUs upon encountering a denormal value when executing a FSQRT, FDIV, or FPREM instruction or upon conversion to BCD or to integer. The operation proceeds by first normalizing the value. On the 16-bit IA-32 math coprocessors, upon encountering this situation, the invalid-operation exception is generated. This difference has no impact on existing software. Software running on the 32-bit x87 FPUs continues to execute in cases where the 16-bit IA-32 math coprocessors trap. The reason for this change was to eliminate an exception from being raised.

### 22.18.6.9 Alignment Check Exceptions (#AC)

If alignment checking is enabled, a misaligned data operand on the P6 family, Pentium, and Intel486 processors causes an alignment check exception (#AC) when a program or procedure is running at privilege-level 3, except for the stack portion of the FSAVE/FNSAVE, FXSAVE, FRSTOR, and FXRSTOR instructions.

### 22.18.6.10 Segment Not Present Exception During FLDENV

On the Intel486 processor, when a segment not present exception (#NP) occurs in the middle of an FLDENV instruction, it can happen that part of the environment is loaded and part not. In such cases, the FPU control word is left with a value of 007FH. The P6 family and Pentium processors ensure the internal state is correct at all times by attempting to read the first and last bytes of the environment before updating the internal state.

### 22.18.6.11 Device Not Available Exception (#NM)

The device-not-available exception (#NM, interrupt 7) will occur in the P6 family, Pentium, and Intel486 processors as described in Section 2.5, "Control Registers," Table 2-2, and Chapter 6, "Interrupt 7—Device Not Available Exception (#NM)."

### 22.18.6.12 Coprocessor Segment Overrun Exception

The coprocessor segment overrun exception (interrupt 9) does not occur in the P6 family, Pentium, and Intel486 processors. In situations where the Intel 387 math coprocessor would cause an interrupt 9, the P6 family, Pentium, and Intel486 processors simply abort the instruction. To avoid undetected segment overruns, it is recommended that the floating-point save area be placed in the same page as the TSS. This placement will prevent the FPU environment from being lost if a page fault occurs during the execution of an FLDENV, FRSTOR, or FXRSTOR instruction while the operating system is performing a task switch.

### 22.18.6.13 General Protection Exception (#GP)

A general-protection exception (#GP, interrupt 13) occurs if the starting address of a floating-point operand falls outside a segment's size. An exception handler should be included to report these programming errors.

### 22.18.6.14 Floating-Point Error Exception (#MF)

In real mode and protected mode (not including virtual-8086 mode), interrupt vector 16 must point to the floating-point exception handler. In virtual 8086 mode, the virtual-8086 monitor can be programmed to accommodate a different location of the interrupt vector for floating-point exceptions.

## 22.18.7 Changes to Floating-Point Instructions

This section identifies the differences in floating-point instructions for the various Intel FPU and math coprocessor architectures, the reason for the differences, and their impact on software.

### 22.18.7.1 FDIV, FPREM, and FSQRT Instructions

The 32-bit x87 FPUs support operations on denormalized operands and, when detected, an underflow exception can occur, for compatibility with the IEEE Standard 754. The 16-bit IA-32 math coprocessors do not operate on denormalized operands or return underflow results. Instead, they generate an invalid-operation exception when they detect an underflow condition. An existing underflow exception handler will require change only if it gives different treatment to different opcodes. Also, it is possible that fewer invalid-operation exceptions will occur.

### 22.18.7.2 FSCALE Instruction

With the 32-bit x87 FPUs, the range of the scaling operand is not restricted. If (0 < | ST(1) < 1), the scaling factor is 0; therefore, ST(0) remains unchanged. If the rounded result is not exact or if there was a loss of accuracy (masked underflow), the precision exception is signaled. With the 16-bit IA-32 math coprocessors, the range of the scaling operand is restricted. If (0 < | ST(1) | < 1), the result is undefined and no exception is signaled. The impact of this difference on exiting software is that different results are delivered on the 32-bit and 16-bit FPUs and math coprocessors when (0 < | ST(1) | < 1).

### 22.18.7.3 FPREM1 Instruction

The 32-bit x87 FPUs compute a partial remainder according to IEEE Standard 754. This instruction does not exist on the 16-bit IA-32 math coprocessors. The availability of the FPREM1 instruction has is no impact on existing software.

### 22.18.7.4 FPREM Instruction

On the 32-bit x87 FPUs, the condition code flags C0, C3, C1 in the status word correctly reflect the three low-order bits of the quotient following execution of the FPREM instruction. On the 16-bit IA-32 math coprocessors, the quotient bits are incorrect when performing a reduction of $(64^N + M)$ when $(N \geq 1)$ and M is 1 or 2. This difference does not affect existing software; software that works around the bug should not be affected.

### 22.18.7.5 FUCOM, FUCOMP, and FUCOMPP Instructions

When executing the FUCOM, FUCOMP, and FUCOMPP instructions, the 32-bit x87 FPUs perform unordered compare according to IEEE Standard 754. These instructions do not exist on the 16-bit IA-32 math coprocessors. The availability of these new instructions has no impact on existing software.

### 22.18.7.6 FPTAN Instruction

On the 32-bit x87 FPUs, the range of the operand for the FPTAN instruction is much less restricted ($| ST(0) | < 2^{63}$) than on earlier math coprocessors. The instruction reduces the operand internally using an internal $\pi/4$ constant that is more accurate. The range of the operand is restricted to ($| ST(0) | < \pi/4$) on the 16-bit IA-32 math coprocessors; the operand must be reduced to this range using FPREM. This change has no impact on existing software.

### 22.18.7.7 Stack Overflow

On the 32-bit x87 FPUs, if an FPU stack overflow occurs when the invalid-operation exception is masked, the FPU returns the real, integer, or BCD-integer indefinite value to the destination operand, depending on the instruction being executed. On the 16-bit IA-32 math coprocessors, the original operand remains unchanged following a stack overflow, but it is loaded into register ST(1). This difference has no impact on existing software.

### 22.18.7.8 FSIN, FCOS, and FSINCOS Instructions

On the 32-bit x87 FPUs, these instructions perform three common trigonometric functions. These instructions do not exist on the 16-bit IA-32 math coprocessors. The availability of these instructions has no impact on existing software, but using them provides a performance upgrade.

### 22.18.7.9 FPATAN Instruction

On the 32-bit x87 FPUs, the range of operands for the FPATAN instruction is unrestricted. On the 16-bit IA-32 math coprocessors, the absolute value of the operand in register ST(0) must be smaller than the absolute value of the operand in register ST(1). This difference has impact on existing software.

### 22.18.7.10 F2XM1 Instruction

The 32-bit x87 FPUs support a wider range of operands ($-1 < ST(0) < +1$) for the F2XM1 instruction. The supported operand range for the 16-bit IA-32 math coprocessors is ($0 \leq ST(0) \leq 0.5$). This difference has no impact on existing software.

### 22.18.7.11 FLD Instruction

On the 32-bit x87 FPUs, when using the FLD instruction to load an extended-real value, a denormal-operand exception is not generated because the instruction is not arithmetic. The 16-bit IA-32 math coprocessors do report a denormal-operand exception in this situation. This difference does not affect existing software.

On the 32-bit x87 FPUs, loading a denormal value that is in single- or double-real format causes the value to be converted to extended-real format. Loading a denormal value on the 16-bit IA-32 math coprocessors causes the value to be converted to an unnormal. If the next instruction is FXTRACT or FXAM, the 32-bit x87 FPUs will give a different result than the 16-bit IA-32 math coprocessors. This change was made for IEEE Standard 754 compatibility.

On the 32-bit x87 FPUs, loading an SNaN that is in single- or double-real format causes the FPU to generate an invalid-operation exception. The 16-bit IA-32 math coprocessors do not raise an exception when loading a signaling NaN. The invalid-operation exception handler for 16-bit math coprocessor software needs to be updated to handle this condition when porting software to 32-bit FPUs. This change was made for IEEE Standard 754 compatibility.

### 22.18.7.12 FXTRACT Instruction

On the 32-bit x87 FPUs, if the operand is 0 for the FXTRACT instruction, the divide-by-zero exception is reported and $-\infty$ is delivered to register ST(1). If the operand is $+\infty$, no exception is reported. If the operand is 0 on the 16-bit IA-32 math coprocessors, 0 is delivered to register ST(1) and no exception is reported. If the operand is $+\infty$, the invalid-operation exception is reported. These differences have no impact on existing software. Software usually bypasses 0 and $\infty$. This change is due to the IEEE Standard 754 recommendation to fully support the "logb" function.

### 22.18.7.13 Load Constant Instructions

On 32-bit x87 FPUs, rounding control is in effect for the load constant instructions. Rounding control is not in effect for the 16-bit IA-32 math coprocessors. Results for the FLDPI, FLDLN2, FLDLG2, and FLDL2E instructions are the same as for the 16-bit IA-32 math coprocessors when rounding control is set to round to nearest or round to $+\infty$. They are the same for the FLDL2T instruction when rounding control is set to round to nearest, round to $-\infty$, or round to zero. Results are different from the 16-bit IA-32 math coprocessors in the least significant bit of the mantissa if rounding control is set to round to $-\infty$ or round to 0 for the FLDPI, FLDLN2, FLDLG2, and FLDL2E instructions; they are different for the FLDL2T instruction if round to $+\infty$ is specified. These changes were implemented for compatibility with IEEE Standard 754 for Floating-Point Arithmetic recommendations.

#### 22.18.7.14 FSETPM Instruction

With the 32-bit x87 FPUs, the FSETPM instruction is treated as NOP (no operation). This instruction informs the Intel 287 math coprocessor that the processor is in protected mode. This change has no impact on existing software. The 32-bit x87 FPUs handle all addressing and exception-pointer information, whether in protected mode or not.

#### 22.18.7.15 FXAM Instruction

With the 32-bit x87 FPUs, if the FPU encounters an empty register when executing the FXAM instruction, it not generate combinations of C0 through C3 equal to 1101 or 1111. The 16-bit IA-32 math coprocessors may generate these combinations, among others. This difference has no impact on existing software; it provides a performance upgrade to provide repeatable results.

#### 22.18.7.16 FSAVE and FSTENV Instructions

With the 32-bit x87 FPUs, the address of a memory operand pointer stored by FSAVE or FSTENV is undefined if the previous floating-point instruction did not refer to memory

### 22.18.8 Transcendental Instructions

The floating-point results of the P6 family and Pentium processors for transcendental instructions in the core range may differ from the Intel486 processors by about 2 or 3 ulps (see "Transcendental Instruction Accuracy" in Chapter 8, "Programming with the x87 FPU," of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*). Condition code flag C1 of the status word may differ as a result. The exact threshold for underflow and overflow will vary by a few ulps. The P6 family and Pentium processors' results will have a worst case error of less than 1 ulp when rounding to the nearest-even and less than 1.5 ulps when rounding in other modes. The transcendental instructions are guaranteed to be monotonic, with respect to the input operands, throughout the domain supported by the instruction.

Transcendental instructions may generate different results in the round-up flag (C1) on the 32-bit x87 FPUs. The round-up flag is undefined for these instructions on the 16-bit IA-32 math coprocessors. This difference has no impact on existing software.

### 22.18.9 Obsolete Instructions

The 8087 math coprocessor instructions FENI and FDISI and the Intel 287 math coprocessor instruction FSETPM are treated as integer NOP instructions in the 32-bit x87 FPUs. If these opcodes are detected in the instruction stream, no specific operation is performed and no internal states are affected.

### 22.18.10 WAIT/FWAIT Prefix Differences

On the Intel486 processor, when a WAIT/FWAIT instruction precedes a floating-point instruction (one which itself automatically synchronizes with the previous floating-point instruction), the WAIT/FWAIT instruction is treated as a no-op. Pending floating-point exceptions from a previous floating-point instruction are processed not on the WAIT/FWAIT instruction but on the floating-point instruction following the WAIT/FWAIT instruction. In such a case, the report of a floating-point exception may appear one instruction later on the Intel486 processor than on a P6 family or Pentium FPU, or on Intel 387 math coprocessor.

### 22.18.11 Operands Split Across Segments and/or Pages

On the P6 family, Pentium, and Intel486 processor FPUs, when the first half of an operand to be written is inside a page or segment and the second half is outside, a memory fault can cause the first half to be stored but not the second half. In this situation, the Intel 387 math coprocessor stores nothing.

### 22.18.12 FPU Instruction Synchronization

On the 32-bit x87 FPUs, all floating-point instructions are automatically synchronized; that is, the processor automatically waits until the previous floating-point instruction has completed before completing the next floating-point instruction. No explicit WAIT/FWAIT instructions are required to assure this synchronization. For the 8087 math coprocessors, explicit waits are required before each floating-point instruction to ensure synchronization. Although 8087 programs having explicit WAIT instructions execute perfectly on the 32-bit IA-32 processors without reassembly, these WAIT instructions are unnecessary.

## 22.19 SERIALIZING INSTRUCTIONS

Certain instructions have been defined to serialize instruction execution to ensure that modifications to flags, registers and memory are completed before the next instruction is executed (or in P6 family processor terminology "committed to machine state"). Because the P6 family processors use branch-prediction and out-of-order execution techniques to improve performance, instruction execution is not generally serialized until the results of an executed instruction are committed to machine state (see Chapter 2, "Intel® 64 and IA-32 Architectures," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*).

As a result, at places in a program or task where it is critical to have execution completed for all previous instructions before executing the next instruction (for example, at a branch, at the end of a procedure, or in multiprocessor dependent code), it is useful to add a serializing instruction. See Section 8.3, "Serializing Instructions," for more information on serializing instructions.

## 22.20 FPU AND MATH COPROCESSOR INITIALIZATION

Table 9-1 shows the states of the FPUs in the P6 family, Pentium, Intel486 processors and of the Intel 387 math coprocessor and Intel 287 coprocessor following a power-up, reset, or INIT, or following the execution of an FINIT/FNINIT instruction. The following is some additional compatibility information concerning the initialization of x87 FPUs and math coprocessors.

### 22.20.1 Intel® 387 and Intel® 287 Math Coprocessor Initialization

Following an Intel386 processor reset, the processor identifies its coprocessor type (Intel® 287 or Intel® 387 DX math coprocessor) by sampling its ERROR# input some time after the falling edge of RESET# signal and before execution of the first floating-point instruction. The Intel 287 coprocessor keeps its ERROR# output in inactive state after hardware reset; the Intel 387 coprocessor keeps its ERROR# output in active state after hardware reset.

Upon hardware reset or execution of the FINIT/FNINIT instruction, the Intel 387 math coprocessor signals an error condition. The P6 family, Pentium, and Intel486 processors, like the Intel 287 coprocessor, do not.

### 22.20.2 Intel486 SX Processor and Intel 487 SX Math Coprocessor Initialization

When initializing an Intel486 SX processor and an Intel 487 SX math coprocessor, the initialization routine should check the presence of the math coprocessor and should set the FPU related flags (EM, MP, and NE) in control register CR0 accordingly (see Section 2.5, "Control Registers," for a complete description of these flags). Table 22-2 gives the recommended settings for these flags when the math coprocessor is present. The FSTCW instruction will give a value of FFFFH for the Intel486 SX microprocessor and 037FH for the Intel 487 SX math coprocessor.

**Table 22-2. Recommended Values of the EM, MP, and NE Flags for Intel486 SX Microprocessor/Intel 487 SX Math Coprocessor System**

| CR0 Flags | Intel486 SX Processor Only | Intel 487 SX Math Coprocessor Present |
|---|---|---|
| EM | 1 | 0 |
| MP | 0 | 1 |
| NE | 1 | 0, for MS-DOS* systems<br>1, for user-defined exception handler |

The EM and MP flags in register CR0 are interpreted as shown in Table 22-3.

**Table 22-3. EM and MP Flag Interpretation**

| EM | MP | Interpretation |
|---|---|---|
| 0 | 0 | Floating-point instructions are passed to FPU; WAIT/FWAIT and other waiting-type instructions ignore TS. |
| 0 | 1 | Floating-point instructions are passed to FPU; WAIT/FWAIT and other waiting-type instructions test TS. |
| 1 | 0 | Floating-point instructions trap to emulator; WAIT/FWAIT and other waiting-type instructions ignore TS. |
| 1 | 1 | Floating-point instructions trap to emulator; WAIT/FWAIT and other waiting-type instructions test TS. |

Following is an example code sequence to initialize the system and check for the presence of Intel486 SX processor/Intel 487 SX math coprocessor.

```
fninit
fstcw mem_loc
mov ax, mem_loc
cmp ax, 037fh
jz Intel487_SX_Math_CoProcessor_present     ;ax=037fh
jmp Intel486_SX_microprocessor_present      ;ax=ffffh
```

If the Intel 487 SX math coprocessor is not present, the following code can be run to set the CR0 register for the Intel486 SX processor.

```
mov eax, cr0
and eax, fffffffdh  ;make MP=0
or eax, 0024h       ;make EM=1, NE=1
mov cr0, eax
```

This initialization will cause any floating-point instruction to generate a device not available exception (#NH), interrupt 7. The software emulation will then take control to execute these instructions. This code is not required if an Intel 487 SX math coprocessor is present in the system. In that case, the typical initialization routine for the Intel486 SX microprocessor will be adequate.

Also, when designing an Intel486 SX processor based system with an Intel 487 SX math coprocessor, timing loops should be independent of frequency and clocks per instruction. One way to attain this is to implement these loops in hardware and not in software (for example, BIOS).

## 22.21 CONTROL REGISTERS

The following sections identify the new control registers and control register flags and fields that were introduced to the 32-bit IA-32 in various processor families. See Figure 2-7 for the location of these flags and fields in the control registers.

The Pentium III processor introduced one new control flag in control register CR4:

- OSXMMEXCPT (bit 10) — The OS will set this bit if it supports unmasked SIMD floating-point exceptions.

The Pentium II processor introduced one new control flag in control register CR4:

- OSFXSR (bit 9) — The OS supports saving and restoring the Pentium III processor state during context switches.

The Pentium Pro processor introduced three new control flags in control register CR4:

- PAE (bit 5) — Physical address extension. Enables paging mechanism to reference extended physical addresses when set; restricts physical addresses to 32 bits when clear (see also: Section 22.22.1.1, "Physical Memory Addressing Extension").
- PGE (bit 7) — Page global enable. Inhibits flushing of frequently-used or shared pages on CR3 writes (see also: Section 22.22.1.2, "Global Pages").
- PCE (bit 8) — Performance-monitoring counter enable. Enables execution of the RDPMC instruction at any protection level.

The content of CR4 is 0H following a hardware reset.

Control register CR4 was introduced in the Pentium processor. This register contains flags that enable certain new extensions provided in the Pentium processor:

- VME — Virtual-8086 mode extensions. Enables support for a virtual interrupt flag in virtual-8086 mode (see Section 20.3, "Interrupt and Exception Handling in Virtual-8086 Mode").
- PVI — Protected-mode virtual interrupts. Enables support for a virtual interrupt flag in protected mode (see Section 20.4, "Protected-Mode Virtual Interrupts").
- TSD — Time-stamp disable. Restricts the execution of the RDTSC instruction to procedures running at privileged level 0.
- DE — Debugging extensions. Causes an undefined opcode (#UD) exception to be generated when debug registers DR4 and DR5 are references for improved performance (see Section 22.23.3, "Debug Registers DR4 and DR5").
- PSE — Page size extensions. Enables 4-MByte pages with 32-bit paging when set (see Section 4.3, "32-Bit Paging").
- MCE — Machine-check enable. Enables the machine-check exception, allowing exception handling for certain hardware error conditions (see Chapter 15, "Machine-Check Architecture").

The Intel486 processor introduced five new flags in control register CR0:

- NE — Numeric error. Enables the normal mechanism for reporting floating-point numeric errors.
- WP — Write protect. Write-protects read-only pages against supervisor-mode accesses.
- AM — Alignment mask. Controls whether alignment checking is performed. Operates in conjunction with the AC (Alignment Check) flag.
- NW — Not write-through. Enables write-throughs and cache invalidation cycles when clear and disables invalidation cycles and write-throughs that hit in the cache when set.
- CD — Cache disable. Enables the internal cache when clear and disables the cache when set.

The Intel486 processor introduced two new flags in control register CR3:

- PCD — Page-level cache disable. The state of this flag is driven on the PCD# pin during bus cycles that are not paged, such as interrupt acknowledge cycles, when paging is enabled. The PCD# pin is used to control caching in an external cache on a cycle-by-cycle basis.
- PWT — Page-level write-through. The state of this flag is driven on the PWT# pin during bus cycles that are not paged, such as interrupt acknowledge cycles, when paging is enabled. The PWT# pin is used to control write through in an external cache on a cycle-by-cycle basis.

## 22.22 MEMORY MANAGEMENT FACILITIES

The following sections describe the new memory management facilities available in the various IA-32 processors and some compatibility differences.

### 22.22.1 New Memory Management Control Flags

The Pentium Pro processor introduced three new memory management features: physical memory addressing extension, the global bit in page-table entries, and general support for larger page sizes. These features are only available when operating in protected mode.

#### 22.22.1.1 Physical Memory Addressing Extension

The new PAE (physical address extension) flag in control register CR4, bit 5, may enable additional address lines on the processor, allowing extended physical addresses. This option can only be used when paging is enabled, using a new page-table mechanism provided to support the larger physical address range (see Section 4.1, "Paging Modes and Control Bits").

#### 22.22.1.2 Global Pages

The new PGE (page global enable) flag in control register CR4, bit 7, provides a mechanism for preventing frequently used pages from being flushed from the translation lookaside buffer (TLB). When this flag is set, frequently used pages (such as pages containing kernel procedures or common data tables) can be marked global by setting the global flag in a page-directory or page-table entry.

On a task switch or a write to control register CR3 (which normally causes the TLBs to be flushed), the entries in the TLB marked global are not flushed. Marking pages global in this manner prevents unnecessary reloading of the TLB due to TLB misses on frequently used pages. See Section 4.10, "Caching Translation Information" for a detailed description of this mechanism.

#### 22.22.1.3 Larger Page Sizes

The P6 family processors support large page sizes. For 32-bit paging, this facility is enabled with the PSE (page size extension) flag in control register CR4, bit 4. When this flag is set, the processor supports either 4-KByte or 4-MByte page sizes. PAE paging and IA-32e paging support 2-MByte pages regardless of the value of CR4.PSE (see Section 4.4, "PAE Paging" and Section 4.5, "IA-32e Paging"). See Chapter 4, "Paging," for more information about large page sizes.

### 22.22.2 CD and NW Cache Control Flags

The CD and NW flags in control register CR0 were introduced in the Intel486 processor. In the P6 family and Pentium processors, these flags are used to implement a writeback strategy for the data cache; in the Intel486 processor, they implement a write-through strategy. See Table 11-5 for a comparison of these bits on the P6 family, Pentium, and Intel486 processors. For complete information on caching, see Chapter 11, "Memory Cache Control."

### 22.22.3 Descriptor Types and Contents

Operating-system code that manages space in descriptor tables often contains an invalid value in the access-rights field of descriptor-table entries to identify unused entries. Access rights values of 80H and 00H remain invalid for the P6 family, Pentium, Intel486, Intel386, and Intel 286 processors. Other values that were invalid on the Intel 286 processor may be valid on the 32-bit processors because uses for these bits have been defined.

### 22.22.4 Changes in Segment Descriptor Loads

On the Intel386 processor, loading a segment descriptor always causes a locked read and write to set the accessed bit of the descriptor. On the P6 family, Pentium, and Intel486 processors, the locked read and write occur only if the bit is not already set.

## 22.23 DEBUG FACILITIES

The P6 family and Pentium processors include extensions to the Intel486 processor debugging support for breakpoints. To use the new breakpoint features, it is necessary to set the DE flag in control register CR4.

### 22.23.1 Differences in Debug Register DR6

It is not possible to write a 1 to reserved bit 12 in debug status register DR6 on the P6 family and Pentium processors; however, it is possible to write a 1 in this bit on the Intel486 processor. See Table 9-1 for the different setting of this register following a power-up or hardware reset.

### 22.23.2 Differences in Debug Register DR7

The P6 family and Pentium processors determines the type of breakpoint access by the R/W0 through R/W3 fields in debug control register DR7 as follows:

00 Break on instruction execution only.

01 Break on data writes only.

10 Undefined if the DE flag in control register CR4 is cleared; break on I/O reads or writes but not instruction fetches if the DE flag in control register CR4 is set.

11 Break on data reads or writes but not instruction fetches.

On the P6 family and Pentium processors, reserved bits 11, 12, 14 and 15 are hard-wired to 0. On the Intel486 processor, however, bit 12 can be set. See Table 9-1 for the different settings of this register following a power-up or hardware reset.

### 22.23.3 Debug Registers DR4 and DR5

Although the DR4 and DR5 registers are documented as reserved, previous generations of processors aliased references to these registers to debug registers DR6 and DR7, respectively. When debug extensions are not enabled (the DE flag in control register CR4 is cleared), the P6 family and Pentium processors remain compatible with existing software by allowing these aliased references. When debug extensions are enabled (the DE flag is set), attempts to reference registers DR4 or DR5 will result in an invalid-opcode exception (#UD).

## 22.24 RECOGNITION OF BREAKPOINTS

For the Pentium processor, it is recommended that debuggers execute the LGDT instruction before returning to the program being debugged to ensure that breakpoints are detected. This operation does not need to be performed on the P6 family, Intel486, or Intel386 processors.

The implementation of test registers on the Intel486 processor used for testing the cache and TLB has been redesigned using MSRs on the P6 family and Pentium processors. (Note that MSRs used for this function are different on the P6 family and Pentium processors.) The MOV to and from test register instructions generate invalid-opcode exceptions (#UD) on the P6 family processors.

## 22.25 EXCEPTIONS AND/OR EXCEPTION CONDITIONS

This section describes the new exceptions and exception conditions added to the 32-bit IA-32 processors and implementation differences in existing exception handling. See Chapter 6, "Interrupt and Exception Handling," for a detailed description of the IA-32 exceptions.

The Pentium III processor introduced new state with the XMM registers. Computations involving data in these registers can produce exceptions. A new MXCSR control/status register is used to determine which exception or exceptions have occurred. When an exception associated with the XMM registers occurs, an interrupt is generated.

- SIMD floating-point exception (#XM, interrupt 19) — New exceptions associated with the SIMD floating-point registers and resulting computations.

No new exceptions were added with the Pentium Pro and Pentium II processors. The set of available exceptions is the same as for the Pentium processor. However, the following exception condition was added to the IA-32 with the Pentium Pro processor:

- Machine-check exception (#MC, interrupt 18) — New exception conditions. Many exception conditions have been added to the machine-check exception and a new architecture has been added for handling and reporting on hardware errors. See Chapter 15, "Machine-Check Architecture," for a detailed description of the new conditions.

The following exceptions and/or exception conditions were added to the IA-32 with the Pentium processor:

- Machine-check exception (#MC, interrupt 18) — New exception. This exception reports parity and other hardware errors. It is a model-specific exception and may not be implemented or implemented differently in future processors. The MCE flag in control register CR4 enables the machine-check exception. When this bit is clear (which it is at reset), the processor inhibits generation of the machine-check exception.
- General-protection exception (#GP, interrupt 13) — New exception condition added. An attempt to write a 1 to a reserved bit position of a special register causes a general-protection exception to be generated.
- Page-fault exception (#PF, interrupt 14) — New exception condition added. When a 1 is detected in any of the reserved bit positions of a page-table entry, page-directory entry, or page-directory pointer during address translation, a page-fault exception is generated.

The following exception was added to the Intel486 processor:

- Alignment-check exception (#AC, interrupt 17) — New exception. Reports unaligned memory references when alignment checking is being performed.

The following exceptions and/or exception conditions were added to the Intel386 processor:

- Divide-error exception (#DE, interrupt 0)
  - — Change in exception handling. Divide-error exceptions on the Intel386 processors always leave the saved CS:IP value pointing to the instruction that failed. On the 8086 processor, the CS:IP value points to the next instruction.
  - — Change in exception handling. The Intel386 processors can generate the largest negative number as a quotient for the IDIV instruction (80H and 8000H). The 8086 processor generates a divide-error exception instead.
- Invalid-opcode exception (#UD, interrupt 6) — New exception condition added. Improper use of the LOCK instruction prefix can generate an invalid-opcode exception.
- Page-fault exception (#PF, interrupt 14) — New exception condition added. If paging is enabled in a 16-bit program, a page-fault exception can be generated as follows. Paging can be used in a system with 16-bit tasks if all tasks use the same page directory. Because there is no place in a 16-bit TSS to store the PDBR register, switching to a 16-bit task does not change the value of the PDBR register. Tasks ported from the Intel 286 processor should be given 32-bit TSSs so they can make full use of paging.
- General-protection exception (#GP, interrupt 13) — New exception condition added. The Intel386 processor sets a limit of 15 bytes on instruction length. The only way to violate this limit is by putting redundant prefixes before an instruction. A general-protection exception is generated if the limit on instruction length is violated. The 8086 processor has no instruction length limit.

### 22.25.1 Machine-Check Architecture

The Pentium Pro processor introduced a new architecture to the IA-32 for handling and reporting on machine-check exceptions. This machine-check architecture (described in detail in Chapter 15, "Machine-Check Architecture") greatly expands the ability of the processor to report on internal hardware errors.

### 22.25.2 Priority of Exceptions

The priority of exceptions are broken down into several major categories:

1. Traps on the previous instruction
2. External interrupts
3. Faults on fetching the next instruction
4. Faults in decoding the next instruction
5. Faults on executing an instruction

There are no changes in the priority of these major categories between the different processors, however, exceptions within these categories are implementation dependent and may change from processor to processor.

### 22.25.3 Exception Conditions of Legacy SIMD Instructions Operating on MMX Registers

MMX instructions and a subset of SSE, SSE2, SSSE3 instructions operate on MMX registers. The exception conditions of these instructions are described in the following tables.

**Table 22-4. Exception Conditions for Legacy SIMD/MMX Instructions with FP Exception and 16-Byte Alignment**

| Exception | Real | Virtual 8086 | Protected and Compatibility | 64-bit | Cause of Exception |
|---|---|---|---|---|---|
| Invalid Opcode, #UD | X | X | X | X | If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 0. |
| | X | X | X | X | If CR0.EM[bit 2] = 1.<br>If CR4.OSFXSR[bit 9] = 0. |
| | X | X | X | X | If preceded by a LOCK prefix (F0H) |
| | X | X | X | X | If any corresponding CPUID feature flag is '0' |
| #MF | X | X | X | X | If there is a pending X87 FPU exception |
| #NM | X | X | X | X | If CR0.TS[bit 3]=1 |
| Stack, SS(0) | | | X | | For an illegal address in the SS segment |
| | | | | X | If a memory address referencing the SS segment is in a non-canonical form |
| General Protection, #GP(0) | X | X | X | X | Legacy SSE: Memory operand is not 16-byte aligned |
| | | | X | | For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments. |
| | | | | X | If the memory address is in a non-canonical form. |
| | X | X | | | If any part of the operand lies outside the effective address space from 0 to FFFFH |
| #PF(fault-code) | | X | X | X | For a page fault |
| #XM | X | X | X | X | If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 1 |
| | | | | | |
| Applicable Instructions | CVTPD2PI, CVTTPD2PI | | | | |

### Table 22-5. Exception Conditions for Legacy SIMD/MMX Instructions with XMM and FP Exception

| Exception | Real | Virtual 80x86 | Protected and Compatibility | 64-bit | Cause of Exception |
|---|---|---|---|---|---|
| Invalid Opcode, #UD | X | X | X | X | If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 0. |
| | X | X | X | X | If CR0.EM[bit 2] = 1.<br>If CR4.OSFXSR[bit 9] = 0. |
| | X | X | X | X | If preceded by a LOCK prefix (F0H) |
| | X | X | X | X | If any corresponding CPUID feature flag is '0' |
| #MF | X | X | X | X | If there is a pending X87 FPU exception |
| #NM | X | X | X | X | If CR0.TS[bit 3]=1 |
| Stack, SS(0) | | | X | | For an illegal address in the SS segment |
| | | | | X | If a memory address referencing the SS segment is in a non-canonical form |
| General Protection, #GP(0) | | | X | | For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments. |
| | | | | X | If the memory address is in a non-canonical form. |
| | X | X | | | If any part of the operand lies outside the effective address space from 0 to FFFFH |
| #PF(fault-code) | | X | X | X | For a page fault |
| Alignment Check #AC(0) | | X | X | X | If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3. |
| SIMD Floating-point Exception, #XM | X | X | X | X | If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 1 |
| | | | | | |
| Applicable Instructions | CVTPI2PS, CVTPS2PI, CVTTPS2PI | | | | |

### Table 22-6. Exception Conditions for Legacy SIMD/MMX Instructions with XMM and without FP Exception

| Exception | Real | Virtual 80x86 | Protected and Compatibility | 64-bit | Cause of Exception |
|---|---|---|---|---|---|
| Invalid Opcode, #UD | X | X | X | X | If CR0.EM[bit 2] = 1.<br>If CR4.OSFXSR[bit 9] = 0. |
| | X | X | X | X | If preceded by a LOCK prefix (F0H) |
| | X | X | X | X | If any corresponding CPUID feature flag is '0' |
| #MF[1] | X | X | X | X | If there is a pending X87 FPU exception |
| #NM | X | X | X | X | If CR0.TS[bit 3]=1 |
| Stack, SS(0) | | | X | | For an illegal address in the SS segment |
| | | | | X | If a memory address referencing the SS segment is in a non-canonical form |
| General Protection, #GP(0) | | | X | | For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments. |
| | | | | X | If the memory address is in a non-canonical form. |
| | X | X | | | If any part of the operand lies outside the effective address space from 0 to FFFFH |
| #PF(fault-code) | | X | X | X | For a page fault |
| Alignment Check #AC(0) | | X | X | X | If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3. |
| | | | | | |
| Applicable Instructions | CVTPI2PD | | | | |

**NOTES:**

1. Applies to "CVTPI2PD xmm, mm" but not "CVTPI2PD xmm, m64".

**Table 22-7. Exception Conditions for SIMD/MMX Instructions with Memory Reference**

| Exception | Real | Virtual 80x86 | Protected and Compatibility | 64-bit | Cause of Exception |
|---|---|---|---|---|---|
| Invalid Opcode, #UD | X | X | X | X | If CR0.EM[bit 2] = 1. |
| | X | X | X | X | If preceded by a LOCK prefix (F0H) |
| | X | X | X | X | If any corresponding CPUID feature flag is '0' |
| #MF | X | X | X | X | If there is a pending X87 FPU exception |
| #NM | X | X | X | X | If CR0.TS[bit 3]=1 |
| Stack, SS(0) | | | X | | For an illegal address in the SS segment |
| | | | | X | If a memory address referencing the SS segment is in a non-canonical form |
| General Protection, #GP(0) | | | X | | For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments. |
| | | | | X | If the memory address is in a non-canonical form. |
| | X | X | | | If any part of the operand lies outside the effective address space from 0 to FFFFH |
| #PF(fault-code) | | X | X | X | For a page fault |
| Alignment Check #AC(0) | | X | X | X | If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3. |
| | | | | | |

| Applicable Instructions | PEXTRW, PMOVMSKB | | | | |

## 22.26 INTERRUPTS

The following differences in handling interrupts are found among the IA-32 processors.

### 22.26.1 Interrupt Propagation Delay

External hardware interrupts may be recognized on different instruction boundaries on the P6 family, Pentium, Intel486, and Intel386 processors, due to the superscaler designs of the P6 family and Pentium processors. Therefore, the EIP pushed onto the stack when servicing an interrupt may be different for the P6 family, Pentium, Intel486, and Intel386 processors.

### 22.26.2 NMI Interrupts

After an NMI interrupt is recognized by the P6 family, Pentium, Intel486, Intel386, and Intel 286 processors, the NMI interrupt is masked until the first IRET instruction is executed, unlike the 8086 processor.

### 22.26.3 IDT Limit

The LIDT instruction can be used to set a limit on the size of the IDT. A double-fault exception (#DF) is generated if an interrupt or exception attempts to read a vector beyond the limit. Shutdown then occurs on the 32-bit IA-32 processors if the double-fault handler vector is beyond the limit. (The 8086 processor does not have a shutdown mode nor a limit.)

## 22.27 ADVANCED PROGRAMMABLE INTERRUPT CONTROLLER (APIC)

The Advanced Programmable Interrupt Controller (APIC), referred to in this book as the **local APIC**, was introduced into the IA-32 processors with the Pentium processor (beginning with the 735/90 and 815/100 models) and is included in the Pentium 4, Intel Xeon, and P6 family processors. The features and functions of the local APIC are derived from the Intel 82489DX external APIC, which was used with the Intel486 and early Pentium processors. Additional refinements of the local APIC architecture were incorporated in the Pentium 4 and Intel Xeon processors.

### 22.27.1 Software Visible Differences Between the Local APIC and the 82489DX

The following features in the local APIC features differ from those found in the 82489DX external APIC:

- When the local APIC is disabled by clearing the APIC software enable/disable flag in the spurious-interrupt vector MSR, the state of its internal registers are unaffected, except that the mask bits in the LVT are all set to block local interrupts to the processor. Also, the local APIC ceases accepting IPIs except for INIT, SMI, NMI, and start-up IPIs. In the 82489DX, when the local unit is disabled, all the internal registers including the IRR, ISR and TMR are cleared and the mask bits in the LVT are set. In this state, the 82489DX local unit will accept only the reset deassert message.
- In the local APIC, NMI and INIT (except for INIT deassert) are always treated as edge triggered interrupts, even if programmed otherwise. In the 82489DX, these interrupts are always level triggered.
- In the local APIC, IPIs generated through the ICR are always treated as edge triggered (except INIT Deassert). In the 82489DX, the ICR can be used to generate either edge or level triggered IPIs.
- In the local APIC, the logical destination register supports 8 bits; in the 82489DX, it supports 32 bits.
- In the local APIC, the APIC ID register is 4 bits wide; in the 82489DX, it is 8 bits wide.
- The remote read delivery mode provided in the 82489DX and local APIC for Pentium processors is not supported in the local APIC in the Pentium 4, Intel Xeon, and P6 family processors.
- For the 82489DX, in the lowest priority delivery mode, all the target local APICs specified by the destination field participate in the lowest priority arbitration. For the local APIC, only those local APICs which have free interrupt slots will participate in the lowest priority arbitration.

### 22.27.2 New Features Incorporated in the Local APIC for the P6 Family and Pentium Processors

The local APIC in the Pentium and P6 family processors have the following new features not found in the 82489DX external APIC.

- Cluster addressing is supported in logical destination mode.
- Focus processor checking can be enabled/disabled.
- Interrupt input signal polarity can be programmed for the LINT0 and LINT1 pins.
- An SMI IPI is supported through the ICR and I/O redirection table.
- An error status register is incorporated into the LVT to log and report APIC errors.

In the P6 family processors, the local APIC incorporates an additional LVT register to handle performance monitoring counter interrupts.

### 22.27.3 New Features Incorporated in the Local APIC of the Pentium 4 and Intel Xeon Processors

The local APIC in the Pentium 4 and Intel Xeon processors has the following new features not found in the P6 family and Pentium processors and in the 82489DX.

- The local APIC ID is extended to 8 bits.
- An thermal sensor register is incorporated into the LVT to handle thermal sensor interrupts.
- The the ability to deliver lowest-priority interrupts to a focus processor is no longer supported.
- The flat cluster logical destination mode is not supported.

## 22.28 TASK SWITCHING AND TSS

This section identifies the implementation differences of task switching, additions to the TSS and the handling of TSSs and TSS segment selectors.

### 22.28.1 P6 Family and Pentium Processor TSS

When the virtual mode extensions are enabled (by setting the VME flag in control register CR4), the TSS in the P6 family and Pentium processors contain an interrupt redirection bit map, which is used in virtual-8086 mode to redirect interrupts back to an 8086 program.

### 22.28.2 TSS Selector Writes

During task state saves, the Intel486 processor writes 2-byte segment selectors into a 32-bit TSS, leaving the upper 16 bits undefined. For performance reasons, the P6 family and Pentium processors write 4-byte segment selectors into the TSS, with the upper 2 bytes being 0. For compatibility reasons, code should not depend on the value of the upper 16 bits of the selector in the TSS.

### 22.28.3 Order of Reads/Writes to the TSS

The order of reads and writes into the TSS is processor dependent. The P6 family and Pentium processors may generate different page-fault addresses in control register CR2 in the same TSS area than the Intel486 and Intel386 processors, if a TSS crosses a page boundary (which is not recommended).

### 22.28.4 Using A 16-Bit TSS with 32-Bit Constructs

Task switches using 16-bit TSSs should be used only for pure 16-bit code. Any new code written using 32-bit constructs (operands, addressing, or the upper word of the EFLAGS register) should use only 32-bit TSSs. This is due to the fact that the 32-bit processors do not save the upper 16 bits of EFLAGS to a 16-bit TSS. A task switch back to a 16-bit task that was executing in virtual mode will never re-enable the virtual mode, as this flag was not saved in the upper half of the EFLAGS value in the TSS. Therefore, it is strongly recommended that any code using 32-bit constructs use a 32-bit TSS to ensure correct behavior in a multitasking environment.

### 22.28.5 Differences in I/O Map Base Addresses

The Intel486 processor considers the TSS segment to be a 16-bit segment and wraps around the 64K boundary. Any I/O accesses check for permission to access this I/O address at the I/O base address plus the I/O offset. If the I/O map base address exceeds the specified limit of 0DFFFH, an I/O access will wrap around and obtain the permission for the I/O address at an incorrect location within the TSS. A TSS limit violation does not occur in this situation on the Intel486 processor. However, the P6 family and Pentium processors consider the TSS to be a 32-bit segment and a limit violation occurs when the I/O base address plus the I/O offset is greater than the TSS limit. By following the recommended specification for the I/O base address to be less than 0DFFFH, the Intel486 processor will not wrap around and access incorrect locations within the TSS for I/O port validation and the P6 family and Pentium processors will not experience general-protection exceptions (#GP). Figure 22-1 demonstrates the different areas accessed by the Intel486 and the P6 family and Pentium processors.

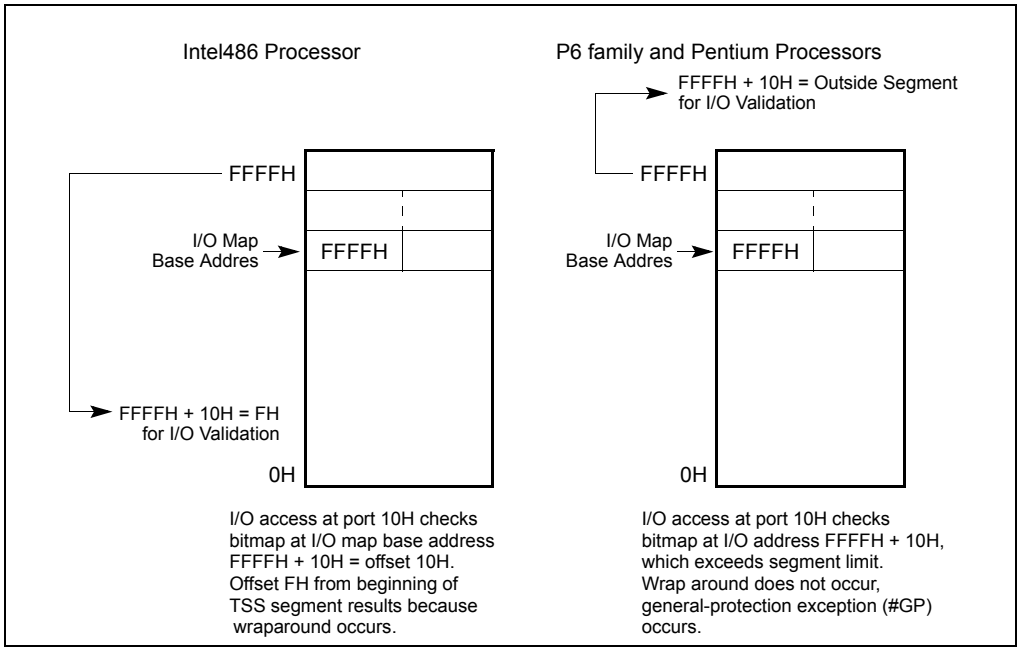

**Figure 22-1. I/O Map Base Address Differences**

## 22.29 CACHE MANAGEMENT

The P6 family processors include two levels of internal caches: L1 (level 1) and L2 (level 2). The L1 cache is divided into an instruction cache and a data cache; the L2 cache is a general-purpose cache. See Section 11.1, "Internal Caches, TLBs, and Buffers," for a description of these caches. (Note that although the Pentium II processor L2 cache is physically located on a separate chip in the cassette, it is considered an internal cache.)

The Pentium processor includes separate level 1 instruction and data caches. The data cache supports a writeback (or alternatively write-through, on a line by line basis) policy for memory updates.

The Intel486 processor includes a single level 1 cache for both instructions and data.

The meaning of the CD and NW flags in control register CR0 have been redefined for the P6 family and Pentium processors. For these processors, the recommended value (00B) enables writeback for the data cache of the Pentium processor and for the L1 data cache and L2 cache of the P6 family processors. In the Intel486 processor, setting these flags to (00B) enables write-through for the cache.

External system hardware can force the Pentium processor to disable caching or to use the write-through cache policy should that be required. In the P6 family processors, the MTRRs can be used to override the CD and NW flags (see Table 11-6).

The P6 family and Pentium processors support page-level cache management in the same manner as the Intel486 processor by using the PCD and PWT flags in control register CR3, the page-directory entries, and the page-table entries. The Intel486 processor, however, is not affected by the state of the PWT flag since the internal cache of the Intel486 processor is a write-through cache.

### 22.29.1 Self-Modifying Code with Cache Enabled

On the Intel486 processor, a write to an instruction in the cache will modify it in both the cache and memory. If the instruction was prefetched before the write, however, the old version of the instruction could be the one executed. To prevent this problem, it is necessary to flush the instruction prefetch unit of the Intel486 processor by coding a jump instruction immediately after any write that modifies an instruction. The P6 family and Pentium processors, however, check whether a write may modify an instruction that has been prefetched for execution. This check is based on the linear address of the instruction. If the linear address of an instruction is found to be present in the

prefetch queue, the P6 family and Pentium processors flush the prefetch queue, eliminating the need to code a jump instruction after any writes that modify an instruction.

Because the linear address of the write is checked against the linear address of the instructions that have been prefetched, special care must be taken for self-modifying code to work correctly when the physical addresses of the instruction and the written data are the same, but the linear addresses differ. In such cases, it is necessary to execute a serializing operation to flush the prefetch queue after the write and before executing the modified instruction. See Section 8.3, "Serializing Instructions," for more information on serializing instructions.

**NOTE**

The check on linear addresses described above is not in practice a concern for compatibility. Applications that include self-modifying code use the same linear address for modifying and fetching the instruction. System software, such as a debugger, that might possibly modify an instruction using a different linear address than that used to fetch the instruction must execute a serializing operation, such as IRET, before the modified instruction is executed.

### 22.29.2 Disabling the L3 Cache

A unified third-level (L3) cache in processors based on Intel NetBurst microarchitecture (see Section 11.1, "Internal Caches, TLBs, and Buffers") provides the third-level cache disable flag, bit 6 of the IA32_MISC_ENABLE MSR. The third-level cache disable flag allows the L3 cache to be disabled and enabled, independently of the L1 and L2 caches (see Section 11.5.4, "Disabling and Enabling the L3 Cache"). The third-level cache disable flag applies only to processors based on Intel NetBurst microarchitecture. Processors with L3 and based on other microarchitectures do not support the third-level cache disable flag.

## 22.30 PAGING

This section identifies enhancements made to the paging mechanism and implementation differences in the paging mechanism for various IA-32 processors.

### 22.30.1 Large Pages

The Pentium processor extended the memory management/paging facilities of the IA-32 to allow large (4 MBytes) pages sizes (see Section 4.3, "32-Bit Paging"). The first P6 family processor (the Pentium Pro processor) added a 2 MByte page size to the IA-32 in conjunction with the physical address extension (PAE) feature (see Section 4.4, "PAE Paging").

The availability of large pages with 32-bit paging on any IA-32 processor can be determined via feature bit 3 (PSE) of register EDX after the CPUID instruction has been execution with an argument of 1. (Large pages are always available with PAE paging and IA-32e paging.) Intel processors that do not support the CPUID instruction support only 32-bit paging and do not support page size enhancements. (See "CPUID—CPU Identification" in Chapter 3, "Instruction Set Reference, A-M," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*, and AP-485, *Intel Processor Identification and the CPUID Instruction*, for more information on the CPUID instruction.)

### 22.30.2 PCD and PWT Flags

The PCD and PWT flags were introduced to the IA-32 in the Intel486 processor to control the caching of pages:

- PCD (page-level cache disable) flag—Controls caching on a page-by-page basis.
- PWT (page-level write-through) flag—Controls the write-through/writeback caching policy on a page-by-page basis. Since the internal cache of the Intel486 processor is a write-through cache, it is not affected by the state of the PWT flag.

### 22.30.3 Enabling and Disabling Paging

Paging is enabled and disabled by loading a value into control register CR0 that modifies the PG flag. For backward and forward compatibility with all IA-32 processors, Intel recommends that the following operations be performed when enabling or disabling paging:

1. Execute a MOV CR0, REG instruction to either set (enable paging) or clear (disable paging) the PG flag.
2. Execute a near JMP instruction.

The sequence bounded by the MOV and JMP instructions should be identity mapped (that is, the instructions should reside on a page whose linear and physical addresses are identical).

For the P6 family processors, the MOV CR0, REG instruction is serializing, so the jump operation is not required. However, for backwards compatibility, the JMP instruction should still be included.

## 22.31 STACK OPERATIONS

This section identifies the differences in the stack mechanism for the various IA-32 processors.

### 22.31.1 Selector Pushes and Pops

When pushing a segment selector onto the stack, the Pentium 4, Intel Xeon, P6 family, and Intel486 processors decrement the ESP register by the operand size and then write 2 bytes. If the operand size is 32-bits, the upper two bytes of the write are not modified. The Pentium processor decrements the ESP register by the operand size and determines the size of the write by the operand size. If the operand size is 32-bits, the upper two bytes are written as 0s.

When popping a segment selector from the stack, the Pentium 4, Intel Xeon, P6 family, and Intel486 processors read 2 bytes and increment the ESP register by the operand size of the instruction. The Pentium processor determines the size of the read from the operand size and increments the ESP register by the operand size.

It is possible to align a 32-bit selector push or pop such that the operation generates an exception on a Pentium processor and not on an Pentium 4, Intel Xeon, P6 family, or Intel486 processor. This could occur if the third and/or fourth byte of the operation lies beyond the limit of the segment or if the third and/or fourth byte of the operation is locate on a non-present or inaccessible page.

For a POP-to-memory instruction that meets the following conditions:

- The stack segment size is 16-bit.
- Any 32-bit addressing form with the SIB byte specifying ESP as the base register.
- The initial stack pointer is FFFCH (32-bit operand) or FFFEH (16-bit operand) and will wrap around to 0H as a result of the POP operation.

The result of the memory write is implementation-specific. For example, in P6 family processors, the result of the memory write is SS:0H plus any scaled index and displacement. In Pentium processors, the result of the memory write may be either a stack fault (real mode or protected mode with stack segment size of 64 KByte), or write to SS:10000H plus any scaled index and displacement (protected mode and stack segment size exceeds 64 KByte).

### 22.31.2 Error Code Pushes

The Intel486 processor implements the error code pushed on the stack as a 16-bit value. When pushed onto a 32-bit stack, the Intel486 processor only pushes 2 bytes and updates ESP by 4. The P6 family and Pentium processors' error code is a full 32 bits with the upper 16 bits set to zero. The P6 family and Pentium processors, therefore, push 4 bytes and update ESP by 4. Any code that relies on the state of the upper 16 bits may produce inconsistent results.

### 22.31.3 Fault Handling Effects on the Stack

During the handling of certain instructions, such as CALL and PUSHA, faults may occur in different sequences for the different processors. For example, during far calls, the Intel486 processor pushes the old CS and EIP before a possible branch fault is resolved. A branch fault is a fault from a branch instruction occurring from a segment limit or access rights violation. If a branch fault is taken, the Intel486 and P6 family processors will have corrupted memory below the stack pointer. However, the ESP register is backed up to make the instruction restartable. The P6 family processors issue the branch before the pushes. Therefore, if a branch fault does occur, these processors do not corrupt memory below the stack pointer. This implementation difference, however, does not constitute a compatibility problem, as only values at or above the stack pointer are considered to be valid. Other operations that encounter faults may also corrupt memory below the stack pointer and this behavior may vary on different implementations.

### 22.31.4 Interlevel RET/IRET From a 16-Bit Interrupt or Call Gate

If a call or interrupt is made from a 32-bit stack environment through a 16-bit gate, only 16 bits of the old ESP can be pushed onto the stack. On the subsequent RET/IRET, the 16-bit ESP is popped but the full 32-bit ESP is updated since control is being resumed in a 32-bit stack environment. The Intel486 processor writes the SS selector into the upper 16 bits of ESP. The P6 family and Pentium processors write zeros into the upper 16 bits.

## 22.32 MIXING 16- AND 32-BIT SEGMENTS

The features of the 16-bit Intel 286 processor are an object-code compatible subset of those of the 32-bit IA-32 processors. The D (default operation size) flag in segment descriptors indicates whether the processor treats a code or data segment as a 16-bit or 32-bit segment; the B (default stack size) flag in segment descriptors indicates whether the processor treats a stack segment as a 16-bit or 32-bit segment.

The segment descriptors used by the Intel 286 processor are supported by the 32-bit IA-32 processors if the Intel-reserved word (highest word) of the descriptor is clear. On the 32-bit IA-32 processors, this word includes the upper bits of the base address and the segment limit.

The segment descriptors for data segments, code segments, local descriptor tables (there are no descriptors for global descriptor tables), and task gates are the same for the 16- and 32-bit processors. Other 16-bit descriptors (TSS segment, call gate, interrupt gate, and trap gate) are supported by the 32-bit processors.

The 32-bit processors also have descriptors for TSS segments, call gates, interrupt gates, and trap gates that support the 32-bit architecture. Both kinds of descriptors can be used in the same system.

For those segment descriptors common to both 16- and 32-bit processors, clear bits in the reserved word cause the 32-bit processors to interpret these descriptors exactly as an Intel 286 processor does, that is:

- Base Address — The upper 8 bits of the 32-bit base address are clear, which limits base addresses to 24 bits.
- Limit — The upper 4 bits of the limit field are clear, restricting the value of the limit field to 64 KBytes.
- Granularity bit — The G (granularity) flag is clear, indicating the value of the 16-bit limit is interpreted in units of 1 byte.
- Big bit — In a data-segment descriptor, the B flag is clear in the segment descriptor used by the 32-bit processors, indicating the segment is no larger than 64 KBytes.
- Default bit — In a code-segment descriptor, the D flag is clear, indicating 16-bit addressing and operands are the default. In a stack-segment descriptor, the D flag is clear, indicating use of the SP register (instead of the ESP register) and a 64-KByte maximum segment limit.

For information on mixing 16- and 32-bit code in applications, see Chapter 21, “Mixing 16-Bit and 32-Bit Code.”

## 22.33 SEGMENT AND ADDRESS WRAPAROUND

This section discusses differences in segment and address wraparound between the P6 family, Pentium, Intel486, Intel386, Intel 286, and 8086 processors.

### 22.33.1 Segment Wraparound

On the 8086 processor, an attempt to access a memory operand that crosses offset 65,535 or 0FFFFH or offset 0 (for example, moving a word to offset 65,535 or pushing a word when the stack pointer is set to 1) causes the offset to wrap around modulo 65,536 or 010000H. With the Intel 286 processor, any base and offset combination that addresses beyond 16 MBytes wraps around to the 1 MByte of the address space. The P6 family, Pentium, Intel486, and Intel386 processors in real-address mode generate an exception in these cases:

- A general-protection exception (#GP) if the segment is a data segment (that is, if the CS, DS, ES, FS, or GS register is being used to address the segment).
- A stack-fault exception (#SS) if the segment is a stack segment (that is, if the SS register is being used).

An exception to this behavior occurs when a stack access is data aligned, and the stack pointer is pointing to the last aligned piece of data that size at the top of the stack (ESP is FFFFFFFCH). When this data is popped, no segment limit violation occurs and the stack pointer will wrap around to 0.

The address space of the P6 family, Pentium, and Intel486 processors may wraparound at 1 MByte in real-address mode. An external A20M# pin forces wraparound if enabled. On Intel 8086 processors, it is possible to specify addresses greater than 1 MByte. For example, with a selector value FFFFH and an offset of FFFFH, the effective address would be 10FFEFH (1 MByte plus 65519 bytes). The 8086 processor, which can form addresses up to 20 bits long, truncates the uppermost bit, which "wraps" this address to FFEFH. However, the P6 family, Pentium, and Intel486 processors do not truncate this bit if A20M# is not enabled.

If a stack operation wraps around the address limit, shutdown occurs. (The 8086 processor does not have a shut-down mode or a limit.)

The behavior when executing near the limit of a 4-GByte selector (limit = FFFFFFFFH) is different between the Pentium Pro and the Pentium 4 family of processors. On the Pentium Pro, instructions which cross the limit -- for example, a two byte instruction such as INC EAX that is encoded as FFH C0H starting exactly at the limit faults for a segment violation (a one byte instruction at FFFFFFFFH does not cause an exception). Using the Pentium 4 micro-processor family, neither of these situations causes a fault.

Segment wraparound and the functionality of A20M# is used primarily by older operating systems and not used by modern operating systems. On newer Intel 64 processors, A20M# may be absent.

## 22.34 STORE BUFFERS AND MEMORY ORDERING

The Pentium 4, Intel Xeon, and P6 family processors provide a store buffer for temporary storage of writes (stores) to memory (see Section 11.10, "Store Buffer"). Writes stored in the store buffer(s) are always written to memory in program order, with the exception of "fast string" store operations (see Section 8.2.4, "Fast-String Operation and Out-of-Order Stores").

The Pentium processor has two store buffers, one corresponding to each of the pipelines. Writes in these buffers are always written to memory in the order they were generated by the processor core.

It should be noted that only memory writes are buffered and I/O writes are not. The Pentium 4, Intel Xeon, P6 family, Pentium, and Intel486 processors do not synchronize the completion of memory writes on the bus and instruction execution after a write. An I/O, locked, or serializing instruction needs to be executed to synchronize writes with the next instruction (see Section 8.3, "Serializing Instructions").

The Pentium 4, Intel Xeon, and P6 family processors use processor ordering to maintain consistency in the order that data is read (loaded) and written (stored) in a program and the order the processor actually carries out the reads and writes. With this type of ordering, reads can be carried out speculatively and in any order, reads can pass buffered writes, and writes to memory are always carried out in program order. (See Section 8.2, "Memory Ordering," for more information about processor ordering.) The Pentium III processor introduced a new instruction to serialize writes and make them globally visible. Memory ordering issues can arise between a producer and a consumer of data. The SFENCE instruction provides a performance-efficient way of ensuring ordering between routines that produce weakly-ordered results and routines that consume this data.

No re-ordering of reads occurs on the Pentium processor, except under the condition noted in Section 8.2.1, "Memory Ordering in the Intel® Pentium® and Intel486™ Processors," and in the following paragraph describing the Intel486 processor.

Specifically, the store buffers are flushed before the IN instruction is executed. No reads (as a result of cache miss) are reordered around previously generated writes sitting in the store buffers. The implication of this is that the store buffers will be flushed or emptied before a subsequent bus cycle is run on the external bus.

On both the Intel486 and Pentium processors, under certain conditions, a memory read will go onto the external bus before the pending memory writes in the buffer even though the writes occurred earlier in the program execution. A memory read will only be reordered in front of all writes pending in the buffers if all writes pending in the buffers are cache hits and the read is a cache miss. Under these conditions, the Intel486 and Pentium processors will not read from an external memory location that needs to be updated by one of the pending writes.

During a locked bus cycle, the Intel486 processor will always access external memory, it will never look for the location in the on-chip cache. All data pending in the Intel486 processor's store buffers will be written to memory before a locked cycle is allowed to proceed to the external bus. Thus, the locked bus cycle can be used for eliminating the possibility of reordering read cycles on the Intel486 processor. The Pentium processor does check its cache on a read-modify-write access and, if the cache line has been modified, writes the contents back to memory before locking the bus. The P6 family processors write to their cache on a read-modify-write operation (if the access does not split across a cache line) and does not write back to system memory. If the access does split across a cache line, it locks the bus and accesses system memory.

I/O reads are never reordered in front of buffered memory writes on an IA-32 processor. This ensures an update of all memory locations before reading the status from an I/O device.

## 22.35 BUS LOCKING

The Intel 286 processor performs the bus locking differently than the Intel P6 family, Pentium, Intel486, and Intel386 processors. Programs that use forms of memory locking specific to the Intel 286 processor may not run properly when run on later processors.

A locked instruction is guaranteed to lock only the area of memory defined by the destination operand, but may lock a larger memory area. For example, typical 8086 and Intel 286 configurations lock the entire physical memory space. Programmers should not depend on this.

On the Intel 286 processor, the LOCK prefix is sensitive to IOPL. If the CPL is greater than the IOPL, a general-protection exception (#GP) is generated. On the Intel386 DX, Intel486, and Pentium, and P6 family processors, no check against IOPL is performed.

The Pentium processor automatically asserts the LOCK# signal when acknowledging external interrupts. After signaling an interrupt request, an external interrupt controller may use the data bus to send the interrupt vector to the processor. After receiving the interrupt request signal, the processor asserts LOCK# to insure that no other data appears on the data bus until the interrupt vector is received. This bus locking does not occur on the P6 family processors.

## 22.36 BUS HOLD

Unlike the 8086 and Intel 286 processors, but like the Intel386 and Intel486 processors, the P6 family and Pentium processors respond to requests for control of the bus from other potential bus masters, such as DMA controllers, between transfers of parts of an unaligned operand, such as two words which form a doubleword. Unlike the Intel386 processor, the P6 family, Pentium and Intel486 processors respond to bus hold during reset initialization.

## 22.37 MODEL-SPECIFIC EXTENSIONS TO THE IA-32

Certain extensions to the IA-32 are specific to a processor or family of IA-32 processors and may not be implemented or implemented in the same way in future processors. The following sections describe these model-specific extensions. The CPUID instruction indicates the availability of some of the model-specific features.

### 22.37.1 Model-Specific Registers

The Pentium processor introduced a set of model-specific registers (MSRs) for use in controlling hardware functions and performance monitoring. To access these MSRs, two new instructions were added to the IA-32 architecture: read MSR (RDMSR) and write MSR (WRMSR). The MSRs in the Pentium processor are not guaranteed to be duplicated or provided in the next generation IA-32 processors.

The P6 family processors greatly increased the number of MSRs available to software. See Chapter 35, "Model-Specific Registers (MSRs)," for a complete list of the available MSRs. The new registers control the debug extensions, the performance counters, the machine-check exception capability, the machine-check architecture, and the MTRRs. These registers are accessible using the RDMSR and WRMSR instructions. Specific information on some of these new MSRs is provided in the following sections. As with the Pentium processor MSR, the P6 family processor MSRs are not guaranteed to be duplicated or provided in the next generation IA-32 processors.

### 22.37.2 RDMSR and WRMSR Instructions

The RDMSR (read model-specific register) and WRMSR (write model-specific register) instructions recognize a much larger number of model-specific registers in the P6 family processors. (See "RDMSR—Read from Model Specific Register" and "WRMSR—Write to Model Specific Register" in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C* for more information.)

### 22.37.3 Memory Type Range Registers

Memory type range registers (MTRRs) are a new feature introduced into the IA-32 in the Pentium Pro processor. MTRRs allow the processor to optimize memory operations for different types of memory, such as RAM, ROM, frame buffer memory, and memory-mapped I/O.

MTRRs are MSRs that contain an internal map of how physical address ranges are mapped to various types of memory. The processor uses this internal memory map to determine the cacheability of various physical memory locations and the optimal method of accessing memory locations. For example, if a memory location is specified in an MTRR as write-through memory, the processor handles accesses to this location as follows. It reads data from that location in lines and caches the read data or maps all writes to that location to the bus and updates the cache to maintain cache coherency. In mapping the physical address space with MTRRs, the processor recognizes five types of memory: uncacheable (UC), uncacheable, speculatable, write-combining (WC), write-through (WT), write-protected (WP), and writeback (WB).

Earlier IA-32 processors (such as the Intel486 and Pentium processors) used the KEN# (cache enable) pin and external logic to maintain an external memory map and signal cacheable accesses to the processor. The MTRR mechanism simplifies hardware designs by eliminating the KEN# pin and the external logic required to drive it.

See Chapter 9, "Processor Management and Initialization," and Chapter 35, "Model-Specific Registers (MSRs)," for more information on the MTRRs.

### 22.37.4 Machine-Check Exception and Architecture

The Pentium processor introduced a new exception called the machine-check exception (#MC, interrupt 18). This exception is used to detect hardware-related errors, such as a parity error on a read cycle.

The P6 family processors extend the types of errors that can be detected and that generate a machine-check exception. It also provides a new machine-check architecture for recording information about a machine-check error and provides extended recovery capability.

The machine-check architecture provides several banks of reporting registers for recording machine-check errors. Each bank of registers is associated with a specific hardware unit in the processor. The primary focus of the machine checks is on bus and interconnect operations; however, checks are also made of translation lookaside buffer (TLB) and cache operations.

The machine-check architecture can correct some errors automatically and allow for reliable restart of instruction execution. It also collects sufficient information for software to use in correcting other machine errors not corrected by hardware.

See Chapter 15, “Machine-Check Architecture,” for more information on the machine-check exception and the machine-check architecture.

### 22.37.5 Performance-Monitoring Counters

The P6 family and Pentium processors provide two performance-monitoring counters for use in monitoring internal hardware operations. The number of performance monitoring counters and associated programming interfaces may be implementation specific for Pentium 4 processors, Pentium M processors. Later processors may have implemented these as part of an architectural performance monitoring feature. The architectural and non-architectural performance monitoring interfaces for different processor families are described in Chapter 18, “Performance Monitoring,”. Chapter 19, “Performance Monitoring Events.” lists all the events that can be counted for architectural performance monitoring events and non-architectural events. The counters are set up, started, and stopped using two MSRs and the RDMSR and WRMSR instructions. For the P6 family processors, the current count for a particular counter can be read using the new RDPMC instruction.

The performance-monitoring counters are useful for debugging programs, optimizing code, diagnosing system failures, or refining hardware designs. See Chapter 18, “Performance Monitoring,” for more information on these counters.

## 22.38 TWO WAYS TO RUN INTEL 286 PROCESSOR TASKS

When porting 16-bit programs to run on 32-bit IA-32 processors, there are two approaches to consider:

- Porting an entire 16-bit software system to a 32-bit processor, complete with the old operating system, loader, and system builder. Here, all tasks will have 16-bit TSSs. The 32-bit processor is being used as if it were a faster version of the 16-bit processor.
- Porting selected 16-bit applications to run in a 32-bit processor environment with a 32-bit operating system, loader, and system builder. Here, the TSSs used to represent 286 tasks should be changed to 32-bit TSSs. It is possible to mix 16 and 32-bit TSSs, but the benefits are small and the problems are great. All tasks in a 32-bit software system should have 32-bit TSSs. It is not necessary to change the 16-bit object modules themselves; TSSs are usually constructed by the operating system, by the loader, or by the system builder. See Chapter 21, “Mixing 16-Bit and 32-Bit Code,” for more detailed information about mixing 16-bit and 32-bit code.

Because the 32-bit processors use the contents of the reserved word of 16-bit segment descriptors, 16-bit programs that place values in this word may not run correctly on the 32-bit processors.

# CHAPTER 23
# INTRODUCTION TO VIRTUAL-MACHINE EXTENSIONS

## 23.1 OVERVIEW

This chapter describes the basics of virtual machine architecture and an overview of the virtual-machine extensions (VMX) that support virtualization of processor hardware for multiple software environments.

Information about VMX instructions is provided in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*. Other aspects of VMX and system programming considerations are described in chapters of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3B*.

## 23.2 VIRTUAL MACHINE ARCHITECTURE

Virtual-machine extensions define processor-level support for virtual machines on IA-32 processors. Two principal classes of software are supported:

- **Virtual-machine monitors (VMM) —** A VMM acts as a host and has full control of the processor(s) and other platform hardware. A VMM presents guest software (see next paragraph) with an abstraction of a virtual processor and allows it to execute directly on a logical processor. A VMM is able to retain selective control of processor resources, physical memory, interrupt management, and I/O.
- **Guest software —** Each virtual machine (VM) is a guest software environment that supports a stack consisting of operating system (OS) and application software. Each operates independently of other virtual machines and uses on the same interface to processor(s), memory, storage, graphics, and I/O provided by a physical platform. The software stack acts as if it were running on a platform with no VMM. Software executing in a virtual machine must operate with reduced privilege so that the VMM can retain control of platform resources.

## 23.3 INTRODUCTION TO VMX OPERATION

Processor support for virtualization is provided by a form of processor operation called VMX operation. There are two kinds of VMX operation: VMX root operation and VMX non-root operation. In general, a VMM will run in VMX root operation and guest software will run in VMX non-root operation. Transitions between VMX root operation and VMX non-root operation are called VMX transitions. There are two kinds of VMX transitions. Transitions into VMX non-root operation are called VM entries. Transitions from VMX non-root operation to VMX root operation are called VM exits.

Processor behavior in VMX root operation is very much as it is outside VMX operation. The principal differences are that a set of new instructions (the VMX instructions) is available and that the values that can be loaded into certain control registers are limited (see Section 23.8).

Processor behavior in VMX non-root operation is restricted and modified to facilitate virtualization. Instead of their ordinary operation, certain instructions (including the new VMCALL instruction) and events cause VM exits to the VMM. Because these VM exits replace ordinary behavior, the functionality of software in VMX non-root operation is limited. It is this limitation that allows the VMM to retain control of processor resources.

There is no software-visible bit whose setting indicates whether a logical processor is in VMX non-root operation. This fact may allow a VMM to prevent guest software from determining that it is running in a virtual machine.

Because VMX operation places restrictions even on software running with current privilege level (CPL) 0, guest software can run at the privilege level for which it was originally designed. This capability may simplify the development of a VMM.

## 23.4 LIFE CYCLE OF VMM SOFTWARE

Figure 23-1 illustrates the life cycle of a VMM and its guest software as well as the interactions between them. The following items summarize that life cycle:

- Software enters VMX operation by executing a VMXON instruction.
- Using VM entries, a VMM can then enter guests into virtual machines (one at a time). The VMM effects a VM entry using instructions VMLAUNCH and VMRESUME; it regains control using VM exits.
- VM exits transfer control to an entry point specified by the VMM. The VMM can take action appropriate to the cause of the VM exit and can then return to the virtual machine using a VM entry.
- Eventually, the VMM may decide to shut itself down and leave VMX operation. It does so by executing the VMXOFF instruction.

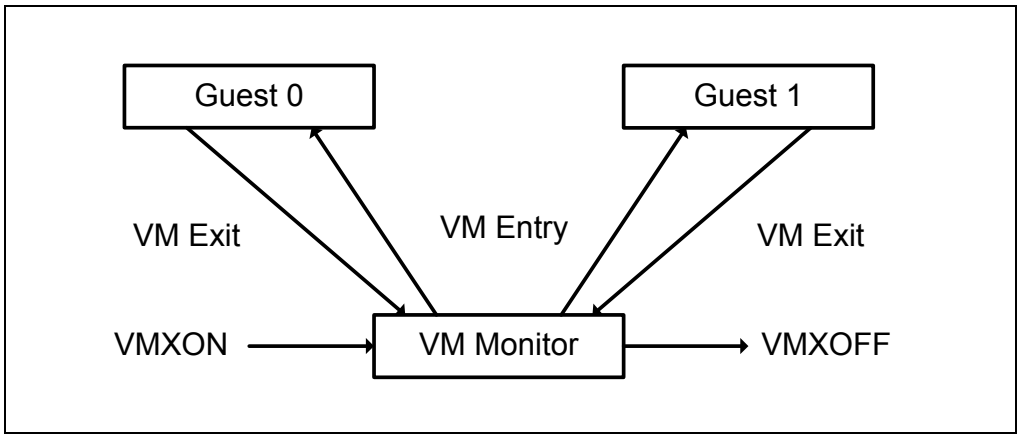

Figure 23-1. Interaction of a Virtual-Machine Monitor and Guests

## 23.5 VIRTUAL-MACHINE CONTROL STRUCTURE

VMX non-root operation and VMX transitions are controlled by a data structure called a virtual-machine control structure (VMCS).

Access to the VMCS is managed through a component of processor state called the VMCS pointer (one per logical processor). The value of the VMCS pointer is the 64-bit address of the VMCS. The VMCS pointer is read and written using the instructions VMPTRST and VMPTRLD. The VMM configures a VMCS using the VMREAD, VMWRITE, and VMCLEAR instructions.

A VMM could use a different VMCS for each virtual machine that it supports. For a virtual machine with multiple logical processors (virtual processors), the VMM could use a different VMCS for each virtual processor.

## 23.6 DISCOVERING SUPPORT FOR VMX

Before system software enters into VMX operation, it must discover the presence of VMX support in the processor. System software can determine whether a processor supports VMX operation using CPUID. If CPUID.1:ECX.VMX[bit 5] = 1, then VMX operation is supported. See Chapter 3, "Instruction Set Reference, A-M" of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*.

The VMX architecture is designed to be extensible so that future processors in VMX operation can support additional features not present in first-generation implementations of the VMX architecture. The availability of extensible VMX features is reported to software using a set of VMX capability MSRs (see Appendix A, "VMX Capability Reporting Facility").

## 23.7 ENABLING AND ENTERING VMX OPERATION

Before system software can enter VMX operation, it enables VMX by setting CR4.VMXE[bit 13] = 1. VMX operation is then entered by executing the VMXON instruction. VMXON causes an invalid-opcode exception (#UD) if executed with CR4.VMXE = 0. Once in VMX operation, it is not possible to clear CR4.VMXE (see Section 23.8). System software leaves VMX operation by executing the VMXOFF instruction. CR4.VMXE can be cleared outside of VMX operation after executing of VMXOFF.

VMXON is also controlled by the IA32_FEATURE_CONTROL MSR (MSR address 3AH). This MSR is cleared to zero when a logical processor is reset. The relevant bits of the MSR are:

- **Bit 0 is the lock bit.** If this bit is clear, VMXON causes a general-protection exception. If the lock bit is set, WRMSR to this MSR causes a general-protection exception; the MSR cannot be modified until a power-up reset condition. System BIOS can use this bit to provide a setup option for BIOS to disable support for VMX. To enable VMX support in a platform, BIOS must set bit 1, bit 2, or both (see below), as well as the lock bit.
- **Bit 1 enables VMXON in SMX operation.** If this bit is clear, execution of VMXON in SMX operation causes a general-protection exception. Attempts to set this bit on logical processors that do not support both VMX operation (see Section 23.6) and SMX operation (see Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*) cause general-protection exceptions.
- **Bit 2 enables VMXON outside SMX operation.** If this bit is clear, execution of VMXON outside SMX operation causes a general-protection exception. Attempts to set this bit on logical processors that do not support VMX operation (see Section 23.6) cause general-protection exceptions.

### NOTE

A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.

Before executing VMXON, software should allocate a naturally aligned 4-KByte region of memory that a logical processor may use to support VMX operation.[1] This region is called the **VMXON region**. The address of the VMXON region (the VMXON pointer) is provided in an operand to VMXON. Section 24.11.5, "VMXON Region," details how software should initialize and access the VMXON region.

## 23.8 RESTRICTIONS ON VMX OPERATION

VMX operation places restrictions on processor operation. These are detailed below:

- In VMX operation, processors may fix certain bits in CR0 and CR4 to specific values and not support other values. VMXON fails if any of these bits contains an unsupported value (see "VMXON—Enter VMX Operation" in Chapter 30). Any attempt to set one of these bits to an unsupported value while in VMX operation (including VMX root operation) using any of the CLTS, LMSW, or MOV CR instructions causes a general-protection exception. VM entry or VM exit cannot set any of these bits to an unsupported value. Software should consult the VMX capability MSRs IA32_VMX_CR0_FIXED0 and IA32_VMX_CR0_FIXED1 to determine how bits in CR0 are fixed. (see Appendix A.7). For CR4, software should consult the VMX capability MSRs IA32_VMX_CR4_FIXED0 and IA32_VMX_CR4_FIXED1 (see Appendix A.8).

### NOTES

The first processors to support VMX operation require that the following bits be 1 in VMX operation: CR0.PE, CR0.NE, CR0.PG, and CR4.VMXE. The restrictions on CR0.PE and CR0.PG imply that VMX operation is supported only in paged protected mode (including IA-32e mode). Therefore, guest software cannot be run in unpaged protected mode or in real-address mode. See Section 31.2,

1. Future processors may require that a different amount of memory be reserved. If so, this fact is reported to software using the VMX capability-reporting mechanism.

"Supporting Processor Operating Modes in Guest Environments," for a discussion of how a VMM might support guest software that expects to run in unpaged protected mode or in real-address mode.

Later processors support a VM-execution control called "unrestricted guest" (see Section 24.6.2). If this control is 1, CR0.PE and CR0.PG may be 0 in VMX non-root operation (even if the capability MSR IA32_VMX_CR0_FIXED0 reports otherwise).[1] Such processors allow guest software to run in unpaged protected mode or in real-address mode.

- VMXON fails if a logical processor is in A20M mode (see "VMXON—Enter VMX Operation" in Chapter 30). Once the processor is in VMX operation, A20M interrupts are blocked. Thus, it is impossible to be in A20M mode in VMX operation.
- The INIT signal is blocked whenever a logical processor is in VMX root operation. It is not blocked in VMX non-root operation. Instead, INITs cause VM exits (see Section 25.2, "Other Causes of VM Exits").

1. "Unrestricted guest" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the "unrestricted guest" VM-execution control were 0. See Section 24.6.2.

# CHAPTER 24
# VIRTUAL-MACHINE CONTROL STRUCTURES

## 24.1 OVERVIEW

A logical processor uses **virtual-machine control data structures** (**VMCSs**) while it is in VMX operation. These manage transitions into and out of VMX non-root operation (VM entries and VM exits) as well as processor behavior in VMX non-root operation. This structure is manipulated by the new instructions VMCLEAR, VMPTRLD, VMREAD, and VMWRITE.

A VMM can use a different VMCS for each virtual machine that it supports. For a virtual machine with multiple logical processors (virtual processors), the VMM can use a different VMCS for each virtual processor.

A logical processor associates a region in memory with each VMCS. This region is called the **VMCS region**.[1] Software references a specific VMCS using the 64-bit physical address of the region (a **VMCS pointer**). VMCS pointers must be aligned on a 4-KByte boundary (bits 11:0 must be zero). These pointers must not set bits beyond the processor's physical-address width.[2,3]

A logical processor may maintain a number of VMCSs that are **active**. The processor may optimize VMX operation by maintaining the state of an active VMCS in memory, on the processor, or both. At any given time, at most one of the active VMCSs is the **current** VMCS. (This document frequently uses the term "the VMCS" to refer to the current VMCS.) The VMLAUNCH, VMREAD, VMRESUME, and VMWRITE instructions operate only on the current VMCS.

The following items describe how a logical processor determines which VMCSs are active and which is current:

- The memory operand of the VMPTRLD instruction is the address of a VMCS. After execution of the instruction, that VMCS is both active and current on the logical processor. Any other VMCS that had been active remains so, but no other VMCS is current.
- The VMCS link pointer field in the current VMCS (see Section 24.4.2) is itself the address of a VMCS. If VM entry is performed successfully with the 1-setting of the "VMCS shadowing" VM-execution control, the VMCS referenced by the VMCS link pointer field becomes active on the logical processor. The identity of the current VMCS does not change.
- The memory operand of the VMCLEAR instruction is also the address of a VMCS. After execution of the instruction, that VMCS is neither active nor current on the logical processor. If the VMCS had been current on the logical processor, the logical processor no longer has a current VMCS.

The VMPTRST instruction stores the address of the logical processor's current VMCS into a specified memory location (it stores the value FFFFFFFF_FFFFFFFFH if there is no current VMCS).

The **launch state** of a VMCS determines which VM-entry instruction should be used with that VMCS: the VMLAUNCH instruction requires a VMCS whose launch state is "clear"; the VMRESUME instruction requires a VMCS whose launch state is "launched". A logical processor maintains a VMCS's launch state in the corresponding VMCS region. The following items describe how a logical processor manages the launch state of a VMCS:

- If the launch state of the current VMCS is "clear", successful execution of the VMLAUNCH instruction changes the launch state to "launched".
- The memory operand of the VMCLEAR instruction is the address of a VMCS. After execution of the instruction, the launch state of that VMCS is "clear".
- There are no other ways to modify the launch state of a VMCS (it cannot be modified using VMWRITE) and there is no direct way to discover it (it cannot be read using VMREAD).

---

1. The amount of memory required for a VMCS region is at most 4 KBytes. The exact size is implementation specific and can be determined by consulting the VMX capability MSR IA32_VMX_BASIC to determine the size of the VMCS region (see Appendix A.1).
2. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
3. If IA32_VMX_BASIC[48] is read as 1, these pointers must not set any bits in the range 63:32; see Appendix A.1.

Figure 24-1 illustrates the different states of a VMCS. It uses "X" to refer to the VMCS and "Y" to refer to any other VMCS. Thus: "VMPTRLD X" always makes X current and active; "VMPTRLD Y" always makes X not current (because it makes Y current); VMLAUNCH makes the launch state of X "launched" if X was current and its launch state was "clear"; and VMCLEAR X always makes X inactive and not current and makes its launch state "clear".

The figure does not illustrate operations that do not modify the VMCS state relative to these parameters (e.g., execution of VMPTRLD X when X is already current). Note that VMCLEAR X makes X "inactive, not current, and clear," even if X's current state is not defined (e.g., even if X has not yet been initialized). See Section 24.11.3.

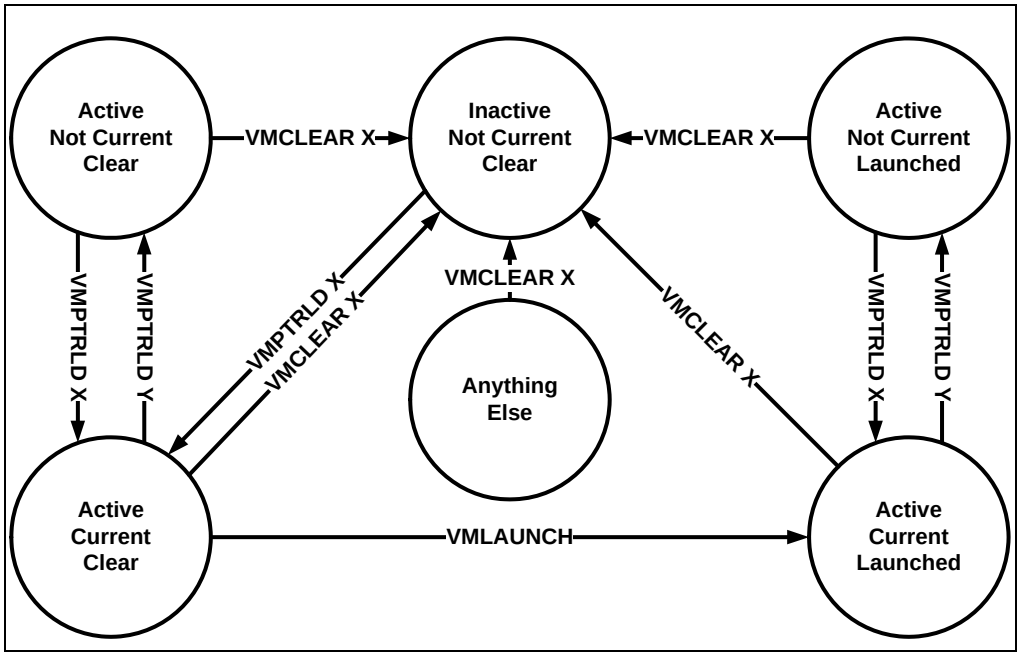

Figure 24-1. States of VMCS X

Because a shadow VMCS (see Section 24.10) cannot be used for VM entry, the launch state of a shadow VMCS is not meaningful. Figure 24-1 does not illustrate all the ways in which a shadow VMCS may be made active.

## 24.2 FORMAT OF THE VMCS REGION

A VMCS region comprises up to 4-KBytes.[1] The format of a VMCS region is given in Table 24-1.

Table 24-1. Format of the VMCS Region

| Byte Offset | Contents |
|---|---|
| 0 | Bits 30:0: VMCS revision identifier<br>Bit 31: shadow-VMCS indicator (see Section 24.10) |
| 4 | VMX-abort indicator |
| 8 | VMCS data (implementation-specific format) |

The first 4 bytes of the VMCS region contain the **VMCS revision identifier** at bits 30:0.[2] Processors that maintain VMCS data in different formats (see below) use different VMCS revision identifiers. These identifiers enable soft-

1. The exact size is implementation specific and can be determined by consulting the VMX capability MSR IA32_VMX_BASIC to determine the size of the VMCS region (see Appendix A.1).

ware to avoid using a VMCS region formatted for one processor on a processor that uses a different format.[1] Bit 31 of this 4-byte region indicates whether the VMCS is a shadow VMCS (see Section 24.10).

Software should write the VMCS revision identifier to the VMCS region before using that region for a VMCS. The VMCS revision identifier is never written by the processor; VMPTRLD fails if its operand references a VMCS region whose VMCS revision identifier differs from that used by the processor. (VMPTRLD also fails if the shadow-VMCS indicator is 1 and the processor does not support the 1-setting of the "VMCS shadowing" VM-execution control; see Section 24.6.2) Software can discover the VMCS revision identifier that a processor uses by reading the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1).

Software should clear or set the shadow-VMCS indicator depending on whether the VMCS is to be an ordinary VMCS or a shadow VMCS (see Section 24.10). VMPTRLD fails if the shadow-VMCS indicator is set and the processor does not support the 1-setting of the "VMCS shadowing" VM-execution control. Software can discover support for this setting by reading the VMX capability MSR IA32_VMX_PROCBASED_CTLS2 (see Appendix A.3.3).

The next 4 bytes of the VMCS region are used for the **VMX-abort indicator**. The contents of these bits do not control processor operation in any way. A logical processor writes a non-zero value into these bits if a VMX abort occurs (see Section 27.7). Software may also write into this field.

The remainder of the VMCS region is used for **VMCS data** (those parts of the VMCS that control VMX non-root operation and the VMX transitions). The format of these data is implementation-specific. VMCS data are discussed in Section 24.3 through Section 24.9. To ensure proper behavior in VMX operation, software should maintain the VMCS region and related structures (enumerated in Section 24.11.4) in writeback cacheable memory. Future implementations may allow or require a different memory type[2]. Software should consult the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1).

## 24.3 ORGANIZATION OF VMCS DATA

The VMCS data are organized into six logical groups:

- **Guest-state area.** Processor state is saved into the guest-state area on VM exits and loaded from there on VM entries.
- **Host-state area.** Processor state is loaded from the host-state area on VM exits.
- **VM-execution control fields.** These fields control processor behavior in VMX non-root operation. They determine in part the causes of VM exits.
- **VM-exit control fields.** These fields control VM exits.
- **VM-entry control fields.** These fields control VM entries.
- **VM-exit information fields.** These fields receive information on VM exits and describe the cause and the nature of VM exits. On some processors, these fields are read-only.[3]

The VM-execution control fields, the VM-exit control fields, and the VM-entry control fields are sometimes referred to collectively as VMX controls.

---

2. Earlier versions of this manual specified that the VMCS revision identifier was a 32-bit field. For all processors produced prior to this change, bit 31 of the VMCS revision identifier was 0.

1. Logical processors that use the same VMCS revision identifier use the same size for VMCS regions.

2. Alternatively, software may map any of these regions or structures with the UC memory type. Doing so is strongly discouraged unless necessary as it will cause the performance of transitions using those structures to suffer significantly. In addition, the processor will continue to use the memory type reported in the VMX capability MSR IA32_VMX_BASIC with exceptions noted in Appendix A.1.

3. Software can discover whether these fields can be written by reading the VMX capability MSR IA32_VMX_MISC (see Appendix A.6).

## 24.4 GUEST-STATE AREA

This section describes fields contained in the guest-state area of the VMCS. As noted earlier, processor state is loaded from these fields on every VM entry (see Section 26.3.2) and stored into these fields on every VM exit (see Section 27.3).

### 24.4.1 Guest Register State

The following fields in the guest-state area correspond to processor registers:

- Control registers CR0, CR3, and CR4 (64 bits each; 32 bits on processors that do not support Intel 64 architecture).
- Debug register DR7 (64 bits; 32 bits on processors that do not support Intel 64 architecture).
- RSP, RIP, and RFLAGS (64 bits each; 32 bits on processors that do not support Intel 64 architecture).[1]
- The following fields for each of the registers CS, SS, DS, ES, FS, GS, LDTR, and TR:
  - Selector (16 bits).
  - Base address (64 bits; 32 bits on processors that do not support Intel 64 architecture). The base-address fields for CS, SS, DS, and ES have only 32 architecturally-defined bits; nevertheless, the corresponding VMCS fields have 64 bits on processors that support Intel 64 architecture.
  - Segment limit (32 bits). The limit field is always a measure in bytes.
  - Access rights (32 bits). The format of this field is given in Table 24-2 and detailed as follows:
    - The low 16 bits correspond to bits 23:8 of the upper 32 bits of a 64-bit segment descriptor. While bits 19:16 of code-segment and data-segment descriptors correspond to the upper 4 bits of the segment limit, the corresponding bits (bits 11:8) are reserved in this VMCS field.
    - Bit 16 indicates an **unusable segment**. Attempts to use such a segment fault except in 64-bit mode. In general, a segment register is unusable if it has been loaded with a null selector.[2]
    - Bits 31:17 are reserved.

**Table 24-2. Format of Access Rights**

| Bit Position(s) | Field |
|---|---|
| 3:0 | Segment type |
| 4 | S — Descriptor type (0 = system; 1 = code or data) |
| 6:5 | DPL — Descriptor privilege level |
| 7 | P — Segment present |
| 11:8 | Reserved |
| 12 | AVL — Available for use by system software |

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.
2. There are a few exceptions to this statement. For example, a segment with a non-null selector may be unusable following a task switch that fails after its commit point; see "Interrupt 10—Invalid TSS Exception (#TS)" in Section 6.14, "Exception and Interrupt Handling in 64-bit Mode," of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*. In contrast, the TR register is usable after processor reset despite having a null selector; see Table 10-1 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

**Table 24-2. Format of Access Rights (Contd.)**

| Bit Position(s) | Field |
|---|---|
| 13 | Reserved (except for CS)<br>L — 64-bit mode active (for CS only) |
| 14 | D/B — Default operation size (0 = 16-bit segment; 1 = 32-bit segment) |
| 15 | G — Granularity |
| 16 | Segment unusable (0 = usable; 1 = unusable) |
| 31:17 | Reserved |

The base address, segment limit, and access rights compose the "hidden" part (or "descriptor cache") of each segment register. These data are included in the VMCS because it is possible for a segment register's descriptor cache to be inconsistent with the segment descriptor in memory (in the GDT or the LDT) referenced by the segment register's selector.

The value of the DPL field for SS is always equal to the logical processor's current privilege level (CPL).[1]

- The following fields for each of the registers GDTR and IDTR:
  - Base address (64 bits; 32 bits on processors that do not support Intel 64 architecture).
  - Limit (32 bits). The limit fields contain 32 bits even though these fields are specified as only 16 bits in the architecture.
- The following MSRs:
  - IA32_DEBUGCTL (64 bits)
  - IA32_SYSENTER_CS (32 bits)
  - IA32_SYSENTER_ESP and IA32_SYSENTER_EIP (64 bits; 32 bits on processors that do not support Intel 64 architecture)
  - IA32_PERF_GLOBAL_CTRL (64 bits). This field is supported only on processors that support the 1-setting of the "load IA32_PERF_GLOBAL_CTRL" VM-entry control.
  - IA32_PAT (64 bits). This field is supported only on processors that support either the 1-setting of the "load IA32_PAT" VM-entry control or that of the "save IA32_PAT" VM-exit control.
  - IA32_EFER (64 bits). This field is supported only on processors that support either the 1-setting of the "load IA32_EFER" VM-entry control or that of the "save IA32_EFER" VM-exit control.
- The register SMBASE (32 bits). This register contains the base address of the logical processor's SMRAM image.

### 24.4.2 Guest Non-Register State

In addition to the register state described in Section 24.4.1, the guest-state area includes the following fields that characterize guest state but which do not correspond to processor registers:

- **Activity state** (32 bits). This field identifies the logical processor's activity state. When a logical processor is executing instructions normally, it is in the **active state**. Execution of certain instructions and the occurrence of certain events may cause a logical processor to transition to an **inactive state** in which it ceases to execute instructions.

  The following activity states are defined:[2]

  - 0: **Active**. The logical processor is executing instructions normally.

1. In protected mode, CPL is also associated with the RPL field in the CS selector. However, the RPL fields are not meaningful in real-address mode or in virtual-8086 mode.
2. Execution of the MWAIT instruction may put a logical processor into an inactive state. However, this VMCS field never reflects this state. See Section 27.1.

— 1: **HLT**. The logical processor is inactive because it executed the HLT instruction.

— 2: **Shutdown**. The logical processor is inactive because it incurred a **triple fault**[1] or some other serious error.

— 3: **Wait-for-SIPI**. The logical processor is inactive because it is waiting for a startup-IPI (SIPI).

Future processors may include support for other activity states. Software should read the VMX capability MSR IA32_VMX_MISC (see Appendix A.6) to determine what activity states are supported.

- **Interruptibility state** (32 bits). The IA-32 architecture includes features that permit certain events to be blocked for a period of time. This field contains information about such blocking. Details and the format of this field are given in Table 24-3.

**Table 24-3. Format of Interruptibility State**

| Bit Position(s) | Bit Name | Notes |
|---|---|---|
| 0 | Blocking by STI | See the "STI—Set Interrupt Flag" section in Chapter 4 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.<br>Execution of STI with RFLAGS.IF = 0 blocks interrupts (and, optionally, other events) for one instruction after its execution. Setting this bit indicates that this blocking is in effect. |
| 1 | Blocking by MOV SS | See the "MOV—Move a Value from the Stack" from Chapter 3 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*, and "POP—Pop a Value from the Stack" from Chapter 4 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*, and Section 6.8.3 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.<br>Execution of a MOV to SS or a POP to SS blocks interrupts for one instruction after its execution. In addition, certain debug exceptions are inhibited between a MOV to SS or a POP to SS and a subsequent instruction. Setting this bit indicates that the blocking of all these events is in effect. This document uses the term "blocking by MOV SS," but it applies equally to POP SS. |
| 2 | Blocking by SMI | See Section 34.2. System-management interrupts (SMIs) are disabled while the processor is in system-management mode (SMM). Setting this bit indicates that blocking of SMIs is in effect. |
| 3 | Blocking by NMI | See Section 6.7.1 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A* and Section 34.8.<br>Delivery of a non-maskable interrupt (NMI) or a system-management interrupt (SMI) blocks subsequent NMIs until the next execution of IRET. See Section 25.3 for how this behavior of IRET may change in VMX non-root operation. Setting this bit indicates that blocking of NMIs is in effect. Clearing this bit does not imply that NMIs are not (temporarily) blocked for other reasons.<br>If the "virtual NMIs" VM-execution control (see Section 24.6.1) is 1, this bit does not control the blocking of NMIs. Instead, it refers to "virtual-NMI blocking" (the fact that guest software is not ready for an NMI). |
| 31:4 | Reserved | VM entry will fail if these bits are not 0. See Section 26.3.1.5. |

- **Pending debug exceptions** (64 bits; 32 bits on processors that do not support Intel 64 architecture). IA-32 processors may recognize one or more debug exceptions without immediately delivering them.[2] This field contains information about such exceptions. This field is described in Table 24-4.

1. A triple fault occurs when a logical processor encounters an exception while attempting to deliver a double fault.
2. For example, execution of a MOV to SS or a POP to SS may inhibit some debug exceptions for one instruction. See Section 6.8.3 of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*. In addition, certain events incident to an instruction (for example, an INIT signal) may take priority over debug traps generated by that instruction. See Table 6-2 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

Table 24-4. Format of Pending-Debug-Exceptions

| Bit Position(s) | Bit Name | Notes |
|---|---|---|
| 3:0 | B3 – B0 | When set, each of these bits indicates that the corresponding breakpoint condition was met. Any of these bits may be set even if the corresponding enabling bit in DR7 is not set. |
| 11:4 | Reserved | VM entry fails if these bits are not 0. See Section 26.3.1.5. |
| 12 | Enabled breakpoint | When set, this bit indicates that at least one data or I/O breakpoint was met and was enabled in DR7. |
| 13 | Reserved | VM entry fails if this bit is not 0. See Section 26.3.1.5. |
| 14 | BS | When set, this bit indicates that a debug exception would have been triggered by single-step execution mode. |
| 63:15 | Reserved | VM entry fails if these bits are not 0. See Section 26.3.1.5. Bits 63:32 exist only on processors that support Intel 64 architecture. |

- **VMCS link pointer** (64 bits). If the "VMCS shadowing" VM-execution control is 1, the VMREAD and VMWRITE instructions access the VMCS referenced by this pointer (see Section 24.10). Otherwise, software should set this field to FFFFFFFF_FFFFFFFFH to avoid VM-entry failures (see Section 26.3.1.5).
- **VMX-preemption timer value** (32 bits). This field is supported only on processors that support the 1-setting of the "activate VMX-preemption timer" VM-execution control. This field contains the value that the VMX-preemption timer will use following the next VM entry with that setting. See Section 25.5.1 and Section 26.6.4.
- **Page-directory-pointer-table entries** (PDPTEs; 64 bits each). These four (4) fields (PDPTE0, PDPTE1, PDPTE2, and PDPTE3) are supported only on processors that support the 1-setting of the "enable EPT" VM-execution control. They correspond to the PDPTEs referenced by CR3 when PAE paging is in use (see Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*). They are used only if the "enable EPT" VM-execution control is 1.
- **Guest interrupt status** (16 bits). This field is supported only on processors that support the 1-setting of the "virtual-interrupt delivery" VM-execution control. It characterizes part of the guest's virtual-APIC state and does not correspond to any processor or APIC registers. It comprises two 8-bit subfields:
  - **Requesting virtual interrupt (RVI)**. This is the low byte of the guest interrupt status. The processor treats this value as the vector of the highest priority virtual interrupt that is requesting service. (The value 0 implies that there is no such interrupt.)
  - **Servicing virtual interrupt (SVI)**. This is the high byte of the guest interrupt status. The processor treats this value as the vector of the highest priority virtual interrupt that is in service. (The value 0 implies that there is no such interrupt.)

  See Chapter 29 for more information on the use of this field.

## 24.5 HOST-STATE AREA

This section describes fields contained in the host-state area of the VMCS. As noted earlier, processor state is loaded from these fields on every VM exit (see Section 27.5).

All fields in the host-state area correspond to processor registers:

- CR0, CR3, and CR4 (64 bits each; 32 bits on processors that do not support Intel 64 architecture).
- RSP and RIP (64 bits each; 32 bits on processors that do not support Intel 64 architecture).
- Selector fields (16 bits each) for the segment registers CS, SS, DS, ES, FS, GS, and TR. There is no field in the host-state area for the LDTR selector.
- Base-address fields for FS, GS, TR, GDTR, and IDTR (64 bits each; 32 bits on processors that do not support Intel 64 architecture).

- The following MSRs:
  - IA32_SYSENTER_CS (32 bits)
  - IA32_SYSENTER_ESP and IA32_SYSENTER_EIP (64 bits; 32 bits on processors that do not support Intel 64 architecture).
  - IA32_PERF_GLOBAL_CTRL (64 bits). This field is supported only on processors that support the 1-setting of the "load IA32_PERF_GLOBAL_CTRL" VM-exit control.
  - IA32_PAT (64 bits). This field is supported only on processors that support the 1-setting of the "load IA32_PAT" VM-exit control.
  - IA32_EFER (64 bits). This field is supported only on processors that support the 1-setting of the "load IA32_EFER" VM-exit control.

In addition to the state identified here, some processor state components are loaded with fixed values on every VM exit; there are no fields corresponding to these components in the host-state area. See Section 27.5 for details of how state is loaded on VM exits.

## 24.6 VM-EXECUTION CONTROL FIELDS

The VM-execution control fields govern VMX non-root operation. These are described in Section 24.6.1 through Section 24.6.8.

### 24.6.1 Pin-Based VM-Execution Controls

The pin-based VM-execution controls constitute a 32-bit vector that governs the handling of asynchronous events (for example: interrupts).[1] Table 24-5 lists the controls. See Chapter 27 for how these controls affect processor behavior in VMX non-root operation.

**Table 24-5. Definitions of Pin-Based VM-Execution Controls**

| Bit Position(s) | Name | Description |
|---|---|---|
| 0 | External-interrupt exiting | If this control is 1, external interrupts cause VM exits. Otherwise, they are delivered normally through the guest interrupt-descriptor table (IDT). If this control is 1, the value of RFLAGS.IF does not affect interrupt blocking. |
| 3 | NMI exiting | If this control is 1, non-maskable interrupts (NMIs) cause VM exits. Otherwise, they are delivered normally using descriptor 2 of the IDT. This control also determines interactions between IRET and blocking by NMI (see Section 25.3). |
| 5 | Virtual NMIs | If this control is 1, NMIs are never blocked and the "blocking by NMI" bit (bit 3) in the interruptibility-state field indicates "virtual-NMI blocking" (see Table 24-3). This control also interacts with the "NMI-window exiting" VM-execution control (see Section 24.6.2). |
| 6 | Activate VMX-preemption timer | If this control is 1, the VMX-preemption timer counts down in VMX non-root operation; see Section 25.5.1. A VM exit occurs when the timer counts down to zero; see Section 25.2. |
| 7 | Process posted interrupts | If this control is 1, the processor treats interrupts with the posted-interrupt notification vector (see Section 24.6.8) specially, updating the virtual-APIC page with posted-interrupt requests (see Section 29.6). |

All other bits in this field are reserved, some to 0 and some to 1. Software should consult the VMX capability MSRs IA32_VMX_PINBASED_CTLS and IA32_VMX_TRUE_PINBASED_CTLS (see Appendix A.3.1) to determine how to set reserved bits. Failure to set reserved bits properly causes subsequent VM entries to fail (see Section 26.2.1.1).

The first processors to support the virtual-machine extensions supported only the 1-settings of bits 1, 2, and 4. The VMX capability MSR IA32_VMX_PINBASED_CTLS will always report that these bits must be 1. Logical processors

1. Some asynchronous events cause VM exits regardless of the settings of the pin-based VM-execution controls (see Section 25.2).

that support the 0-settings of any of these bits will support the VMX capability MSR IA32_VMX_TRUE_PINBASED_CTLS MSR, and software should consult this MSR to discover support for the 0-settings of these bits. Software that is not aware of the functionality of any one of these bits should set that bit to 1.

### 24.6.2 Processor-Based VM-Execution Controls

The processor-based VM-execution controls constitute two 32-bit vectors that govern the handling of synchronous events, mainly those caused by the execution of specific instructions.[1] These are the **primary processor-based VM-execution controls** and the **secondary processor-based VM-execution controls**.

Table 24-6 lists the primary processor-based VM-execution controls. See Chapter 25 for more details of how these controls affect processor behavior in VMX non-root operation.

**Table 24-6. Definitions of Primary Processor-Based VM-Execution Controls**

| Bit Position(s) | Name | Description |
|---|---|---|
| 2 | Interrupt-window exiting | If this control is 1, a VM exit occurs at the beginning of any instruction if RFLAGS.IF = 1 and there are no other blocking of interrupts (see Section 24.4.2). |
| 3 | Use TSC offsetting | This control determines whether executions of RDTSC, executions of RDTSCP, and executions of RDMSR that read from the IA32_TIME_STAMP_COUNTER MSR return a value modified by the TSC offset field (see Section 24.6.5 and Section 25.3). |
| 7 | HLT exiting | This control determines whether executions of HLT cause VM exits. |
| 9 | INVLPG exiting | This determines whether executions of INVLPG cause VM exits. |
| 10 | MWAIT exiting | This control determines whether executions of MWAIT cause VM exits. |
| 11 | RDPMC exiting | This control determines whether executions of RDPMC cause VM exits. |
| 12 | RDTSC exiting | This control determines whether executions of RDTSC and RDTSCP cause VM exits. |
| 15 | CR3-load exiting | In conjunction with the CR3-target controls (see Section 24.6.7), this control determines whether executions of MOV to CR3 cause VM exits. See Section 25.1.3.<br>The first processors to support the virtual-machine extensions supported only the 1-setting of this control. |
| 16 | CR3-store exiting | This control determines whether executions of MOV from CR3 cause VM exits.<br>The first processors to support the virtual-machine extensions supported only the 1-setting of this control. |
| 19 | CR8-load exiting | This control determines whether executions of MOV to CR8 cause VM exits. |
| 20 | CR8-store exiting | This control determines whether executions of MOV from CR8 cause VM exits. |
| 21 | Use TPR shadow | Setting this control to 1 enables TPR virtualization and other APIC-virtualization features. See Chapter 29. |
| 22 | NMI-window exiting | If this control is 1, a VM exit occurs at the beginning of any instruction if there is no virtual-NMI blocking (see Section 24.4.2). |
| 23 | MOV-DR exiting | This control determines whether executions of MOV DR cause VM exits. |
| 24 | Unconditional I/O exiting | This control determines whether executions of I/O instructions (IN, INS/INSB/INSW/INSD, OUT, and OUTS/OUTSB/OUTSW/OUTSD) cause VM exits. |
| 25 | Use I/O bitmaps | This control determines whether I/O bitmaps are used to restrict executions of I/O instructions (see Section 24.6.4 and Section 25.1.3).<br>For this control, "0" means "do not use I/O bitmaps" and "1" means "use I/O bitmaps." If the I/O bitmaps are used, the setting of the "unconditional I/O exiting" control is ignored. |
| 27 | Monitor trap flag | If this control is 1, the monitor trap flag debugging feature is enabled. See Section 25.5.2. |

1. Some instructions cause VM exits regardless of the settings of the processor-based VM-execution controls (see Section 25.1.2), as do task switches (see Section 25.2).

**Table 24-6. Definitions of Primary Processor-Based VM-Execution Controls (Contd.)**

| Bit Position(s) | Name | Description |
|---|---|---|
| 28 | Use MSR bitmaps | This control determines whether MSR bitmaps are used to control execution of the RDMSR and WRMSR instructions (see Section 24.6.9 and Section 25.1.3).<br>For this control, "0" means "do not use MSR bitmaps" and "1" means "use MSR bitmaps." If the MSR bitmaps are not used, all executions of the RDMSR and WRMSR instructions cause VM exits. |
| 29 | MONITOR exiting | This control determines whether executions of MONITOR cause VM exits. |
| 30 | PAUSE exiting | This control determines whether executions of PAUSE cause VM exits. |
| 31 | Activate secondary controls | This control determines whether the secondary processor-based VM-execution controls are used. If this control is 0, the logical processor operates as if all the secondary processor-based VM-execution controls were also 0. |

All other bits in this field are reserved, some to 0 and some to 1. Software should consult the VMX capability MSRs IA32_VMX_PROCBASED_CTLS and IA32_VMX_TRUE_PROCBASED_CTLS (see Appendix A.3.2) to determine how to set reserved bits. Failure to set reserved bits properly causes subsequent VM entries to fail (see Section 26.2.1.1).

The first processors to support the virtual-machine extensions supported only the 1-settings of bits 1, 4–6, 8, 13–16, and 26. The VMX capability MSR IA32_VMX_PROCBASED_CTLS will always report that these bits must be 1. Logical processors that support the 0-settings of any of these bits will support the VMX capability MSR IA32_VMX_TRUE_PROCBASED_CTLS MSR, and software should consult this MSR to discover support for the 0-settings of these bits. Software that is not aware of the functionality of any one of these bits should set that bit to 1.

Bit 31 of the primary processor-based VM-execution controls determines whether the secondary processor-based VM-execution controls are used. If that bit is 0, VM entry and VMX non-root operation function as if all the secondary processor-based VM-execution controls were 0. Processors that support only the 0-setting of bit 31 of the primary processor-based VM-execution controls do not support the secondary processor-based VM-execution controls.

Table 24-7 lists the secondary processor-based VM-execution controls. See Chapter 25 for more details of how these controls affect processor behavior in VMX non-root operation.

**Table 24-7. Definitions of Secondary Processor-Based VM-Execution Controls**

| Bit Position(s) | Name | Description |
|---|---|---|
| 0 | Virtualize APIC accesses | If this control is 1, the logical processor treats specially accesses to the page with the APIC-access address. See Section 29.4. |
| 1 | Enable EPT | If this control is 1, extended page tables (EPT) are enabled. See Section 28.2. |
| 2 | Descriptor-table exiting | This control determines whether executions of LGDT, LIDT, LLDT, LTR, SGDT, SIDT, SLDT, and STR cause VM exits. |
| 3 | Enable RDTSCP | If this control is 0, any execution of RDTSCP causes an invalid-opcode exception (#UD). |
| 4 | Virtualize x2APIC mode | If this control is 1, the logical processor treats specially RDMSR and WRMSR to APIC MSRs (in the range 800H–8FFH). See Section 29.5. |
| 5 | Enable VPID | If this control is 1, cached translations of linear addresses are associated with a virtual-processor identifier (VPID). See Section 28.1. |
| 6 | WBINVD exiting | This control determines whether executions of WBINVD cause VM exits. |
| 7 | Unrestricted guest | This control determines whether guest software may run in unpaged protected mode or in real-address mode. |
| 8 | APIC-register virtualization | If this control is 1, the logical processor virtualizes certain APIC accesses. See Section 29.4 and Section 29.5. |
| 9 | Virtual-interrupt delivery | This controls enables the evaluation and delivery of pending virtual interrupts as well as the emulation of writes to the APIC registers that control interrupt prioritization. |
| 10 | PAUSE-loop exiting | This control determines whether a series of executions of PAUSE can cause a VM exit (see Section 24.6.13 and Section 25.1.3). |

Table 24-7. Definitions of Secondary Processor-Based VM-Execution Controls (Contd.)

| Bit Position(s) | Name | Description |
|---|---|---|
| 11 | RDRAND exiting | This control determines whether executions of RDRAND cause VM exits. |
| 12 | Enable INVPCID | If this control is 0, any execution of INVPCID causes a #UD. |
| 13 | Enable VM functions | Setting this control to 1 enables use of the VMFUNC instruction in VMX non-root operation. See Section 25.5.5. |
| 14 | VMCS shadowing | If this control is 1, executions of VMREAD and VMWRITE in VMX non-root operation may access a shadow VMCS (instead of causing VM exits). See Section 24.10 and Section 30.3. |
| 16 | RDSEED exiting | This control determines whether executions of RDSEED cause VM exits. |
| 18 | EPT-violation #VE | If this control is 1, EPT violations may cause virtualization exceptions (#VE) instead of VM exits. See Section 25.5.6. |
| 20 | Enable XSAVES/XRSTORS | If this control is 0, any execution of XSAVES or XRSTORS causes a #UD. |

All other bits in this field are reserved to 0. Software should consult the VMX capability MSR IA32_VMX_PROCBASED_CTLS2 (see Appendix A.3.3) to determine which bits may be set to 1. Failure to clear reserved bits causes subsequent VM entries to fail (see Section 26.2.1.1).

### 24.6.3 Exception Bitmap

The **exception bitmap** is a 32-bit field that contains one bit for each exception. When an exception occurs, its vector is used to select a bit in this field. If the bit is 1, the exception causes a VM exit. If the bit is 0, the exception is delivered normally through the IDT, using the descriptor corresponding to the exception's vector.

Whether a page fault (exception with vector 14) causes a VM exit is determined by bit 14 in the exception bitmap as well as the error code produced by the page fault and two 32-bit fields in the VMCS (the **page-fault error-code mask** and **page-fault error-code match)**. See Section 25.2 for details.

### 24.6.4 I/O-Bitmap Addresses

The VM-execution control fields include the 64-bit physical addresses of **I/O bitmaps** A and B (each of which are 4 KBytes in size). I/O bitmap A contains one bit for each I/O port in the range 0000H through 7FFFH; I/O bitmap B contains bits for ports in the range 8000H through FFFFH.

A logical processor uses these bitmaps if and only if the "use I/O bitmaps" control is 1. If the bitmaps are used, execution of an I/O instruction causes a VM exit if any bit in the I/O bitmaps corresponding to a port it accesses is 1. See Section 25.1.3 for details. If the bitmaps are used, their addresses must be 4-KByte aligned.

### 24.6.5 Time-Stamp Counter Offset

VM-execution control fields include a 64-bit **TSC-offset** field. If the "RDTSC exiting" control is 0 and the "use TSC offsetting" control is 1, this field controls executions of the RDTSC and RDTSCP instructions. It also controls executions of the RDMSR instruction that read from the IA32_TIME_STAMP_COUNTER MSR. For all of these, the signed value of the TSC offset is combined with the contents of the time-stamp counter (using signed addition) and the sum is reported to guest software in EDX:EAX. See Chapter 27 for a detailed treatment of the behavior of RDTSC, RDTSCP, and RDMSR in VMX non-root operation.

### 24.6.6 Guest/Host Masks and Read Shadows for CR0 and CR4

VM-execution control fields include **guest/host masks** and **read shadows** for the CR0 and CR4 registers. These fields control executions of instructions that access those registers (including CLTS, LMSW, MOV CR, and SMSW). They are 64 bits on processors that support Intel 64 architecture and 32 bits on processors that do not.

In general, bits set to 1 in a guest/host mask correspond to bits "owned" by the host:

- Guest attempts to set them (using CLTS, LMSW, or MOV to CR) to values differing from the corresponding bits in the corresponding read shadow cause VM exits.
- Guest reads (using MOV from CR or SMSW) return values for these bits from the corresponding read shadow.

Bits cleared to 0 correspond to bits "owned" by the guest; guest attempts to modify them succeed and guest reads return values for these bits from the control register itself.

See Chapter 27 for details regarding how these fields affect VMX non-root operation.

### 24.6.7 CR3-Target Controls

The VM-execution control fields include a set of 4 **CR3-target values** and a **CR3-target count**. The CR3-target values each have 64 bits on processors that support Intel 64 architecture and 32 bits on processors that do not. The CR3-target count has 32 bits on all processors.

An execution of MOV to CR3 in VMX non-root operation does not cause a VM exit if its source operand matches one of these values. If the CR3-target count is *n*, only the first *n* CR3-target values are considered; if the CR3-target count is 0, MOV to CR3 always causes a VM exit

There are no limitations on the values that can be written for the CR3-target values. VM entry fails (see Section 26.2) if the CR3-target count is greater than 4.

Future processors may support a different number of CR3-target values. Software should read the VMX capability MSR IA32_VMX_MISC (see Appendix A.6) to determine the number of values supported.

### 24.6.8 Controls for APIC Virtualization

There are three mechanisms by which software accesses registers of the logical processor's local APIC:

- If the local APIC is in xAPIC mode, it can perform memory-mapped accesses to addresses in the 4-KByte page referenced by the physical address in the IA32_APIC_BASE MSR (see Section 10.4.4, "Local APIC Status and Location" in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A* and *Intel® 64 Architecture Processor Topology Enumeration*).[1]
- If the local APIC is in x2APIC mode, it can accesses the local APIC's registers using the RDMSR and WRMSR instructions (see *Intel® 64 Architecture Processor Topology Enumeration*).
- In 64-bit mode, it can access the local APIC's task-priority register (TPR) using the MOV CR8 instruction.

There are five processor-based VM-execution controls (see Section 24.6.2) that control such accesses. There are "use TPR shadow", "virtualize APIC accesses", "virtualize x2APIC mode", "virtual-interrupt delivery", and "APIC-register virtualization". These controls interact with the following fields:

- **APIC-access address** (64 bits). This field contains the physical address of the 4-KByte **APIC-access page**. If the "virtualize APIC accesses" VM-execution control is 1, access to this page may cause VM exits or be virtualized by the processor. See Section 29.4.

  The APIC-access address exists only on processors that support the 1-setting of the "virtualize APIC accesses" VM-execution control.
- **Virtual-APIC address** (64 bits). This field contains the physical address of the 4-KByte **virtual-APIC page**. The processor uses the virtual-APIC page to virtualize certain accesses to APIC registers and to manage virtual interrupts; see Chapter 29.

  Depending on the setting of the controls indicated earlier, the virtual-APIC page may be accessed by the following operations:

  — The MOV CR8 instructions (see Section 29.3).

  — Accesses to the APIC-access page if, in addition, the "virtualize APIC accesses" VM-execution control is 1 (see Section 29.4).

  — The RDMSR and WRMSR instructions if, in addition, the value of ECX is in the range 800H–8FFH (indicating an APIC MSR) and the "virtualize x2APIC mode" VM-execution control is 1 (see Section 29.5).

1. If the local APIC does not support x2APIC mode, it is always in xAPIC mode.

If the "use TPR shadow" VM-execution control is 1, VM entry ensures that the virtual-APIC address is 4-KByte aligned. The virtual-APIC address exists only on processors that support the 1-setting of the "use TPR shadow" VM-execution control.

- **TPR threshold** (32 bits). Bits 3:0 of this field determine the threshold below which bits 7:4 of VTPR (see Section 29.1.1) cannot fall. If the "virtual-interrupt delivery" VM-execution control is 0, a VM exit occurs after an operation (e.g., an execution of MOV to CR8) that reduces the value of those bits below the TPR threshold. See Section 29.1.2.

  The TPR threshold exists only on processors that support the 1-setting of the "use TPR shadow" VM-execution control.
- **EOI-exit bitmap** (4 fields; 64 bits each). These fields are supported only on processors that support the 1-setting of the "virtual-interrupt delivery" VM-execution control. They are used to determine which virtualized writes to the APIC's EOI register cause VM exits:

  — EOI_EXIT0 contains bits for vectors from 0 (bit 0) to 63 (bit 63).

  — EOI_EXIT1 contains bits for vectors from 64 (bit 0) to 127 (bit 63).

  — EOI_EXIT2 contains bits for vectors from 128 (bit 0) to 191 (bit 63).

  — EOI_EXIT3 contains bits for vectors from 192 (bit 0) to 255 (bit 63).

  See Section 29.1.4 for more information on the use of this field.
- **Posted-interrupt notification vector** (16 bits). This field is supported only on processors that support the 1-setting of the "process posted interrupts" VM-execution control. Its low 8 bits contain the interrupt vector that is used to notify a logical processor that virtual interrupts have been posted. See Section 29.6 for more information on the use of this field.
- **Posted-interrupt descriptor address** (64 bits). This field is supported only on processors that support the 1-setting of the "process posted interrupts" VM-execution control. It is the physical address of a 64-byte aligned posted interrupt descriptor. See Section 29.6 for more information on the use of this field.

### 24.6.9 MSR-Bitmap Address

On processors that support the 1-setting of the "use MSR bitmaps" VM-execution control, the VM-execution control fields include the 64-bit physical address of four contiguous **MSR bitmaps**, which are each 1-KByte in size. This field does not exist on processors that do not support the 1-setting of that control. The four bitmaps are:

- **Read bitmap for low MSRs** (located at the MSR-bitmap address)**.** This contains one bit for each MSR address in the range 00000000H to 00001FFFH. The bit determines whether an execution of RDMSR applied to that MSR causes a VM exit.
- **Read bitmap for high MSRs** (located at the MSR-bitmap address plus 1024)**.** This contains one bit for each MSR address in the range C0000000H toC0001FFFH. The bit determines whether an execution of RDMSR applied to that MSR causes a VM exit.
- **Write bitmap for low MSRs** (located at the MSR-bitmap address plus 2048)**.** This contains one bit for each MSR address in the range 00000000H to 00001FFFH. The bit determines whether an execution of WRMSR applied to that MSR causes a VM exit.
- **Write bitmap for high MSRs** (located at the MSR-bitmap address plus 3072)**.** This contains one bit for each MSR address in the range C0000000H toC0001FFFH. The bit determines whether an execution of WRMSR applied to that MSR causes a VM exit.

A logical processor uses these bitmaps if and only if the "use MSR bitmaps" control is 1. If the bitmaps are used, an execution of RDMSR or WRMSR causes a VM exit if the value of RCX is in neither of the ranges covered by the bitmaps or if the appropriate bit in the MSR bitmaps (corresponding to the instruction and the RCX value) is 1. See Section 25.1.3 for details. If the bitmaps are used, their address must be 4-KByte aligned.

### 24.6.10 Executive-VMCS Pointer

The executive-VMCS pointer is a 64-bit field used in the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM). SMM VM exits save this field as described in Section 34.15.2. VM entries that return from SMM use this field as described in Section 34.15.4.

### 24.6.11 Extended-Page-Table Pointer (EPTP)

The **extended-page-table pointer** (EPTP) contains the address of the base of EPT PML4 table (see Section 28.2.2), as well as other EPT configuration information. The format of this field is shown in Table 24-8.

**Table 24-8. Format of Extended-Page-Table Pointer**

| Bit Position(s) | Field |
|---|---|
| 2:0 | EPT paging-structure memory type (see Section 28.2.5):<br>0 = Uncacheable (UC)<br>6 = Write-back (WB)<br><br>Other values are reserved.[1] |
| 5:3 | This value is 1 less than the EPT page-walk length (see Section 28.2.2) |
| 6 | Setting this control to 1 enables accessed and dirty flags for EPT (see Section 28.2.4)[2] |
| 11:7 | Reserved |
| N–1:12 | Bits N–1:12 of the physical address of the 4-KByte aligned EPT PML4 table[3] |
| 63:N | Reserved |

NOTES:

1. Software should read the VMX capability MSR IA32_VMX_EPT_VPID_CAP (see Appendix A.10) to determine what EPT paging-structure memory types are supported.
2. Not all processors support accessed and dirty flags for EPT. Software should read the VMX capability MSR IA32_VMX_EPT_VPID_CAP (see Appendix A.10) to determine whether the processor supports this feature.
3. N is the physical-address width supported by the logical processor. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

The EPTP exists only on processors that support the 1-setting of the "enable EPT" VM-execution control.

### 24.6.12 Virtual-Processor Identifier (VPID)

The **virtual-processor identifier** (VPID) is a 16-bit field. It exists only on processors that support the 1-setting of the "enable VPID" VM-execution control. See Section 28.1 for details regarding the use of this field.

### 24.6.13 Controls for PAUSE-Loop Exiting

On processors that support the 1-setting of the "PAUSE-loop exiting" VM-execution control, the VM-execution control fields include the following 32-bit fields:

- **PLE_Gap**. Software can configure this field as an upper bound on the amount of time between two successive executions of PAUSE in a loop.
- **PLE_Window**. Software can configure this field as an upper bound on the amount of time a guest is allowed to execute in a PAUSE loop.

These fields measure time based on a counter that runs at the same rate as the timestamp counter (TSC). See Section 25.1.3 for more details regarding PAUSE-loop exiting.

### 24.6.14 VM-Function Controls

The **VM-function controls** constitute a 64-bit vector that governs use of the VMFUNC instruction in VMX non-root operation. This field is supported only on processors that support the 1-settings of both the "activate secondary controls" primary processor-based VM-execution control and the "enable VM functions" secondary processor-based VM-execution control.

Table 24-9 lists the VM-function controls. See Section 25.5.5 for more details of how these controls affect processor behavior in VMX non-root operation.

**Table 24-9. Definitions of VM-Function Controls**

| Bit Position(s) | Name | Description |
|---|---|---|
| 0 | EPTP switching | The EPTP-switching VM function changes the EPT pointer to a value chosen from the EPTP list. See Section 25.5.5.3. |

All other bits in this field are reserved to 0. Software should consult the VMX capability MSR IA32_VMX_VMFUNC (see Appendix A.11) to determine which bits are reserved. Failure to clear reserved bits causes subsequent VM entries to fail (see Section 26.2.1.1).

Processors that support the 1-setting of the "EPTP switching" VM-function control also support a 64-bit field called the **EPTP-list address**. This field contains the physical address of the 4-KByte **EPTP list**. The EPTP list comprises 512 8-Byte entries (each an EPTP value) and is used by the EPTP-switching VM function (see Section 25.5.5.3).

### 24.6.15 VMCS Shadowing Bitmap Addresses

On processors that support the 1-setting of the "VMCS shadowing" VM-execution control, the VM-execution control fields include the 64-bit physical addresses of the **VMREAD bitmap** and the **VMWRITE bitmap**. Each bitmap is 4 KBytes in size and thus contains 32 KBits. The addresses are the **VMREAD-bitmap address** and the **VMWRITE-bitmap address**.

If the "VMCS shadowing" VM-execution control is 1, executions of VMREAD and VMWRITE may consult these bitmaps (see Section 24.10 and Section 30.3).

### 24.6.16 Controls for Virtualization Exceptions

On processors that support the 1-setting of the "EPT-violation #VE" VM-execution control, the VM-execution control fields include the following:

- **Virtualization-exception information address** (64 bits). This field contains the physical address of the **virtualization-exception information area**. When a logical processor encounters a virtualization exception, it saves virtualization-exception information at the virtualization-exception information address; see Section 25.5.6.2.
- **EPTP index** (16 bits). When an EPT violation causes a virtualization exception, the processor writes the value of this field to the virtualization-exception information area. The EPTP-switching VM function updates this field (see Section 25.5.5.3).

### 24.6.17 XSS-Exiting Bitmap

On processors that support the 1-setting of the "enable XSAVES/XRSTORS" VM-execution control, the VM-execution control fields include a 64-bit **XSS-exiting bitmap**. If the "enable XSAVES/XRSTORS" VM-execution control is 1, executions of XSAVES and XRSTORS may consult this bitmap (see Section 25.1.3 and Section 25.3).

## 24.7 VM-EXIT CONTROL FIELDS

The VM-exit control fields govern the behavior of VM exits. They are discussed in Section 24.7.1 and Section 24.7.2.

### 24.7.1 VM-Exit Controls

The **VM-exit controls** constitute a 32-bit vector that governs the basic operation of VM exits. Table 24-10 lists the controls supported. See Chapter 27 for complete details of how these controls affect VM exits.

**Table 24-10. Definitions of VM-Exit Controls**

| Bit Position(s) | Name | Description |
|---|---|---|
| 2 | Save debug controls | This control determines whether DR7 and the IA32_DEBUGCTL MSR are saved on VM exit.<br>The first processors to support the virtual-machine extensions supported only the 1-setting of this control. |
| 9 | Host address-space size | On processors that support Intel 64 architecture, this control determines whether a logical processor is in 64-bit mode after the next VM exit. Its value is loaded into CS.L, IA32_EFER.LME, and IA32_EFER.LMA on every VM exit.[1]<br>This control must be 0 on processors that do not support Intel 64 architecture. |
| 12 | Load IA32_PERF_GLOBAL_CTRL | This control determines whether the IA32_PERF_GLOBAL_CTRL MSR is loaded on VM exit. |
| 15 | Acknowledge interrupt on exit | This control affects VM exits due to external interrupts:<br>▪ If such a VM exit occurs and this control is 1, the logical processor acknowledges the interrupt controller, acquiring the interrupt's vector. The vector is stored in the VM-exit interruption-information field, which is marked valid.<br>▪ If such a VM exit occurs and this control is 0, the interrupt is not acknowledged and the VM-exit interruption-information field is marked invalid. |
| 18 | Save IA32_PAT | This control determines whether the IA32_PAT MSR is saved on VM exit. |
| 19 | Load IA32_PAT | This control determines whether the IA32_PAT MSR is loaded on VM exit. |
| 20 | Save IA32_EFER | This control determines whether the IA32_EFER MSR is saved on VM exit. |
| 21 | Load IA32_EFER | This control determines whether the IA32_EFER MSR is loaded on VM exit. |
| 22 | Save VMX-preemption timer value | This control determines whether the value of the VMX-preemption timer is saved on VM exit. |

**NOTES:**

1. Since Intel 64 architecture specifies that IA32_EFER.LMA is always set to the logical-AND of CR0.PG and IA32_EFER.LME, and since CR0.PG is always 1 in VMX operation, IA32_EFER.LMA is always identical to IA32_EFER.LME in VMX operation.

All other bits in this field are reserved, some to 0 and some to 1. Software should consult the VMX capability MSRs IA32_VMX_EXIT_CTLS and IA32_VMX_TRUE_EXIT_CTLS (see Appendix A.4) to determine how it should set the reserved bits. Failure to set reserved bits properly causes subsequent VM entries to fail (see Section 26.2.1.2).

The first processors to support the virtual-machine extensions supported only the 1-settings of bits 0–8, 10, 11, 13, 14, 16, and 17. The VMX capability MSR IA32_VMX_EXIT_CTLS always reports that these bits must be 1. Logical processors that support the 0-settings of any of these bits will support the VMX capability MSR IA32_VMX_TRUE_EXIT_CTLS MSR, and software should consult this MSR to discover support for the 0-settings of these bits. Software that is not aware of the functionality of any one of these bits should set that bit to 1.

### 24.7.2 VM-Exit Controls for MSRs

A VMM may specify lists of MSRs to be stored and loaded on VM exits. The following VM-exit control fields determine how MSRs are stored on VM exits:

- **VM-exit MSR-store count** (32 bits). This field specifies the number of MSRs to be stored on VM exit. It is recommended that this count not exceed 512 bytes.[1] Otherwise, unpredictable processor behavior (including a machine check) may result during VM exit.
- **VM-exit MSR-store address** (64 bits). This field contains the physical address of the VM-exit MSR-store area. The area is a table of entries, 16 bytes per entry, where the number of entries is given by the VM-exit MSR-store count. The format of each entry is given in Table 24-11. If the VM-exit MSR-store count is not zero, the address must be 16-byte aligned.

**Table 24-11. Format of an MSR Entry**

| Bit Position(s) | Contents |
|---|---|
| 31:0 | MSR index |
| 63:32 | Reserved |
| 127:64 | MSR data |

See Section 27.4 for how this area is used on VM exits.

The following VM-exit control fields determine how MSRs are loaded on VM exits:

- **VM-exit MSR-load count** (32 bits). This field contains the number of MSRs to be loaded on VM exit. It is recommended that this count not exceed 512 bytes. Otherwise, unpredictable processor behavior (including a machine check) may result during VM exit.[2]
- **VM-exit MSR-load address** (64 bits). This field contains the physical address of the VM-exit MSR-load area. The area is a table of entries, 16 bytes per entry, where the number of entries is given by the VM-exit MSR-load count (see Table 24-11). If the VM-exit MSR-load count is not zero, the address must be 16-byte aligned.

See Section 27.6 for how this area is used on VM exits.

## 24.8 VM-ENTRY CONTROL FIELDS

The VM-entry control fields govern the behavior of VM entries. They are discussed in Sections 24.8.1 through 24.8.3.

### 24.8.1 VM-Entry Controls

The **VM-entry controls** constitute a 32-bit vector that governs the basic operation of VM entries. Table 24-12 lists the controls supported. See Chapter 24 for how these controls affect VM entries.

All other bits in this field are reserved, some to 0 and some to 1. Software should consult the VMX capability MSRs IA32_VMX_ENTRY_CTLS and IA32_VMX_TRUE_ENTRY_CTLS (see Appendix A.5) to determine how it should set the reserved bits. Failure to set reserved bits properly causes subsequent VM entries to fail (see Section 26.2.1.3).

The first processors to support the virtual-machine extensions supported only the 1-settings of bits 0–8 and 12. The VMX capability MSR IA32_VMX_ENTRY_CTLS always reports that these bits must be 1. Logical processors that support the 0-settings of any of these bits will support the VMX capability MSR IA32_VMX_TRUE_ENTRY_CTLS

1. Future implementations may allow more MSRs to be stored reliably. Software should consult the VMX capability MSR IA32_VMX_MISC to determine the number supported (see Appendix A.6).
2. Future implementations may allow more MSRs to be loaded reliably. Software should consult the VMX capability MSR IA32_VMX_MISC to determine the number supported (see Appendix A.6).

Table 24-12. Definitions of VM-Entry Controls

| Bit Position(s) | Name | Description |
|---|---|---|
| 2 | Load debug controls | This control determines whether DR7 and the IA32_DEBUGCTL MSR are loaded on VM exit.<br>The first processors to support the virtual-machine extensions supported only the 1-setting of this control. |
| 9 | IA-32e mode guest | On processors that support Intel 64 architecture, this control determines whether the logical processor is in IA-32e mode after VM entry. Its value is loaded into IA32_EFER.LMA as part of VM entry.[1]<br>This control must be 0 on processors that do not support Intel 64 architecture. |
| 10 | Entry to SMM | This control determines whether the logical processor is in system-management mode (SMM) after VM entry. This control must be 0 for any VM entry from outside SMM. |
| 11 | Deactivate dual-monitor treatment | If set to 1, the default treatment of SMIs and SMM is in effect after the VM entry (see Section 34.15.7). This control must be 0 for any VM entry from outside SMM. |
| 13 | Load IA32_PERF_GLOBAL_CTRL | This control determines whether the IA32_PERF_GLOBAL_CTRL MSR is loaded on VM entry. |
| 14 | Load IA32_PAT | This control determines whether the IA32_PAT MSR is loaded on VM entry. |
| 15 | Load IA32_EFER | This control determines whether the IA32_EFER MSR is loaded on VM entry. |

NOTES:

1. Bit 5 of the IA32_VMX_MISC MSR is read as 1 on any logical processor that supports the 1-setting of the "unrestricted guest" VM-execution control. If it is read as 1, every VM exit stores the value of IA32_EFER.LMA into the "IA-32e mode guest" VM-entry control (see Section 27.2).

MSR, and software should consult this MSR to discover support for the 0-settings of these bits. Software that is not aware of the functionality of any one of these bits should set that bit to 1.

## 24.8.2 VM-Entry Controls for MSRs

A VMM may specify a list of MSRs to be loaded on VM entries. The following VM-entry control fields manage this functionality:

- **VM-entry MSR-load count** (32 bits). This field contains the number of MSRs to be loaded on VM entry. It is recommended that this count not exceed 512 bytes. Otherwise, unpredictable processor behavior (including a machine check) may result during VM entry.[1]
- **VM-entry MSR-load address** (64 bits). This field contains the physical address of the VM-entry MSR-load area. The area is a table of entries, 16 bytes per entry, where the number of entries is given by the VM-entry MSR-load count. The format of entries is described in Table 24-11. If the VM-entry MSR-load count is not zero, the address must be 16-byte aligned.

See Section 26.4 for details of how this area is used on VM entries.

## 24.8.3 VM-Entry Controls for Event Injection

VM entry can be configured to conclude by delivering an event through the IDT (after all guest state and MSRs have been loaded). This process is called **event injection** and is controlled by the following three VM-entry control fields:

- **VM-entry interruption-information field** (32 bits). This field provides details about the event to be injected. Table 24-13 describes the field.

1. Future implementations may allow more MSRs to be loaded reliably. Software should consult the VMX capability MSR IA32_VMX_MISC to determine the number supported (see Appendix A.6).

Table 24-13. Format of the VM-Entry Interruption-Information Field

| Bit Position(s) | Content |
|---|---|
| 7:0 | Vector of interrupt or exception |
| 10:8 | Interruption type:<br>0: External interrupt<br>1: Reserved<br>2: Non-maskable interrupt (NMI)<br>3: Hardware exception<br>4: Software interrupt<br>5: Privileged software exception<br>6: Software exception<br>7: Other event |
| 11 | Deliver error code (0 = do not deliver; 1 = deliver) |
| 30:12 | Reserved |
| 31 | Valid |

  - The **vector** (bits 7:0) determines which entry in the IDT is used or which other event is injected.
  - The **interruption type** (bits 10:8) determines details of how the injection is performed. In general, a VMM should use the type **hardware exception** for all exceptions other than breakpoint exceptions (#BP; generated by INT3) and overflow exceptions (#OF; generated by INTO); it should use the type **software exception** for #BP and #OF. The type **other event** is used for injection of events that are not delivered through the IDT.
  - For exceptions, the **deliver-error-code bit** (bit 11) determines whether delivery pushes an error code on the guest stack.
  - VM entry injects an event if and only if the **valid bit** (bit 31) is 1. The valid bit in this field is cleared on every VM exit (see Section 27.2).
- **VM-entry exception error code** (32 bits). This field is used if and only if the valid bit (bit 31) and the deliver-error-code bit (bit 11) are both set in the VM-entry interruption-information field.
- **VM-entry instruction length** (32 bits). For injection of events whose type is software interrupt, software exception, or privileged software exception, this field is used to determine the value of RIP that is pushed on the stack.

See Section 26.5 for details regarding the mechanics of event injection, including the use of the interruption type and the VM-entry instruction length.

VM exits clear the valid bit (bit 31) in the VM-entry interruption-information field.

## 24.9 VM-EXIT INFORMATION FIELDS

The VMCS contains a section of fields that contain information about the most recent VM exit.

On some processors, attempts to write to these fields with VMWRITE fail (see "VMWRITE—Write Field to Virtual-Machine Control Structure" in Chapter 30).[1]

### 24.9.1 Basic VM-Exit Information

The following VM-exit information fields provide basic information about a VM exit:

1. Software can discover whether these fields can be written by reading the VMX capability MSR IA32_VMX_MISC (see Appendix A.6).

- **Exit reason** (32 bits). This field encodes the reason for the VM exit and has the structure given in Table 24-14.

**Table 24-14. Format of Exit Reason**

| Bit Position(s) | Contents |
|---|---|
| 15:0 | Basic exit reason |
| 27:16 | Reserved (cleared to 0) |
| 28 | Pending MTF VM exit |
| 29 | VM exit from VMX root operation |
| 30 | Reserved (cleared to 0) |
| 31 | VM-entry failure (0 = true VM exit; 1 = VM-entry failure) |

  - Bits 15:0 provide basic information about the cause of the VM exit (if bit 31 is clear) or of the VM-entry failure (if bit 31 is set). Appendix C enumerates the basic exit reasons.
  - Bit 28 is set only by an SMM VM exit (see Section 34.15.2) that took priority over an MTF VM exit (see Section 25.5.2) that would have occurred had the SMM VM exit not occurred. See Section 34.15.2.3.
  - Bit 29 is set if and only if the processor was in VMX root operation at the time the VM exit occurred. This can happen only for SMM VM exits. See Section 34.15.2.
  - Because some VM-entry failures load processor state from the host-state area (see Section 26.7), software must be able to distinguish such cases from true VM exits. Bit 31 is used for that purpose.
- **Exit qualification** (64 bits; 32 bits on processors that do not support Intel 64 architecture). This field contains additional information about the cause of VM exits due to the following: debug exceptions; page-fault exceptions; start-up IPIs (SIPIs); task switches; INVEPT; INVLPG;INVVPID; LGDT; LIDT; LLDT; LTR; SGDT; SIDT; SLDT; STR; VMCLEAR; VMPTRLD; VMPTRST; VMREAD; VMWRITE; VMXON; control-register accesses; MOV DR; I/O instructions; and MWAIT. The format of the field depends on the cause of the VM exit. See Section 27.2.1 for details.
- **Guest-linear address** (64 bits; 32 bits on processors that do not support Intel 64 architecture). This field is used in the following cases:
  - VM exits due to attempts to execute LMSW with a memory operand.
  - VM exits due to attempts to execute INS or OUTS.
  - VM exits due to system-management interrupts (SMIs) that arrive immediately after retirement of I/O instructions.
  - Certain VM exits due to EPT violations

  See Section 27.2.1 and Section 34.15.2.3 for details of when and how this field is used.
- **Guest-physical address** (64 bits). This field is used VM exits due to EPT violations and EPT misconfigurations. See Section 27.2.1 for details of when and how this field is used.

## 24.9.2 Information for VM Exits Due to Vectored Events

Event-specific information is provided for VM exits due to the following vectored events: exceptions (including those generated by the instructions INT3, INTO, BOUND, and UD2); external interrupts that occur while the "acknowledge interrupt on exit" VM-exit control is 1; and non-maskable interrupts (NMIs). This information is provided in the following fields:

- **VM-exit interruption information** (32 bits). This field receives basic information associated with the event causing the VM exit. Table 24-15 describes this field.

Table 24-15. Format of the VM-Exit Interruption-Information Field

| Bit Position(s) | Content |
|---|---|
| 7:0 | Vector of interrupt or exception |
| 10:8 | Interruption type:<br>0: External interrupt<br>1: Not used<br>2: Non-maskable interrupt (NMI)<br>3: Hardware exception<br>4 – 5: Not used<br>6: Software exception<br>7: Not used |
| 11 | Error code valid (0 = invalid; 1 = valid) |
| 12 | NMI unblocking due to IRET |
| 30:13 | Reserved (cleared to 0) |
| 31 | Valid |

- **VM-exit interruption error code** (32 bits). For VM exits caused by hardware exceptions that would have delivered an error code on the stack, this field receives that error code.

Section 27.2.2 provides details of how these fields are saved on VM exits.

### 24.9.3 Information for VM Exits That Occur During Event Delivery

Additional information is provided for VM exits that occur during event delivery in VMX non-root operation.[1] This information is provided in the following fields:

- **IDT-vectoring information** (32 bits). This field receives basic information associated with the event that was being delivered when the VM exit occurred. Table 24-16 describes this field.

Table 24-16. Format of the IDT-Vectoring Information Field

| Bit Position(s) | Content |
|---|---|
| 7:0 | Vector of interrupt or exception |
| 10:8 | Interruption type:<br>0: External interrupt<br>1: Not used<br>2: Non-maskable interrupt (NMI)<br>3: Hardware exception<br>4: Software interrupt<br>5: Privileged software exception<br>6: Software exception<br>7: Not used |
| 11 | Error code valid (0 = invalid; 1 = valid) |
| 12 | Undefined |
| 30:13 | Reserved (cleared to 0) |
| 31 | Valid |

- **IDT-vectoring error code** (32 bits). For VM exits the occur during delivery of hardware exceptions that would have delivered an error code on the stack, this field receives that error code.

See Section 27.2.3 provides details of how these fields are saved on VM exits.

1. This includes cases in which the event delivery was caused by event injection as part of VM entry; see Section 26.5.1.2.

### 24.9.4 Information for VM Exits Due to Instruction Execution

The following fields are used for VM exits caused by attempts to execute certain instructions in VMX non-root operation:

- **VM-exit instruction length** (32 bits). For VM exits resulting from instruction execution, this field receives the length in bytes of the instruction whose execution led to the VM exit.[1] See Section 27.2.4 for details of when and how this field is used.
- **VM-exit instruction information** (32 bits). This field is used for VM exits due to attempts to execute INS, INVEPT, INVVPID, LIDT, LGDT, LLDT, LTR, OUTS, SIDT, SGDT, SLDT, STR, VMCLEAR, VMPTRLD, VMPTRST, VMREAD, VMWRITE, or VMXON.[2] The format of the field depends on the cause of the VM exit. See Section 27.2.4 for details.

The following fields (64 bits each; 32 bits on processors that do not support Intel 64 architecture) are used only for VM exits due to SMIs that arrive immediately after retirement of I/O instructions. They provide information about that I/O instruction:

- **I/O RCX**. The value of RCX before the I/O instruction started.
- **I/O RSI**. The value of RSI before the I/O instruction started.
- **I/O RDI**. The value of RDI before the I/O instruction started.
- **I/O RIP**. The value of RIP before the I/O instruction started (the RIP that addressed the I/O instruction).

### 24.9.5 VM-Instruction Error Field

The 32-bit **VM-instruction error field** does not provide information about the most recent VM exit. In fact, it is not modified on VM exits. Instead, it provides information about errors encountered by a non-faulting execution of one of the VMX instructions.

## 24.10 VMCS TYPES: ORDINARY AND SHADOW

Every VMCS is either an **ordinary VMCS** or a **shadow VMCS**. A VMCS's type is determined by the shadow-VMCS indicator in the VMCS region (this is the value of bit 31 of the first 4 bytes of the VMCS region; see Table 24-1): 0 indicates an ordinary VMCS, while 1 indicates a shadow VMCS. Shadow VMCSs are supported only on processors that support the 1-setting of the "VMCS shadowing" VM-execution control (see Section 24.6.2).

A shadow VMCS differs from an ordinary VMCS in two ways:

- An ordinary VMCS can be used for VM entry but a shadow VMCS cannot. Attempts to perform VM entry when the current VMCS is a shadow VMCS fail (see Section 26.1).
- The VMREAD and VMWRITE instructions can be used in VMX non-root operation to access a shadow VMCS but not an ordinary VMCS. This fact results from the following:
  - If the "VMCS shadowing" VM-execution control is 0, execution of the VMREAD and VMWRITE instructions in VMX non-root operation always cause VM exits (see Section 25.1.3).
  - If the "VMCS shadowing" VM-execution control is 1, execution of the VMREAD and VMWRITE instructions in VMX non-root operation can access the VMCS referenced by the VMCS link pointer (see Section 30.3).
  - If the "VMCS shadowing" VM-execution control is 1, VM entry ensures that any VMCS referenced by the VMCS link pointer is a shadow VMCS (see Section 26.3.1.5).

In VMX root operation, both types of VMCSs can be accessed with the VMREAD and VMWRITE instructions.

Software should not modify the shadow-VMCS indicator in the VMCS region of a VMCS that is active. Doing so may cause the VMCS to become corrupted (see Section 24.11.1). Before modifying the shadow-VMCS indicator, software should execute VMCLEAR for the VMCS to ensure that it is not active.

---

1. This field is also used for VM exits that occur during the delivery of a software interrupt or software exception.
2. Whether the processor provides this information on VM exits due to attempts to execute INS or OUTS can be determined by consulting the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1).

# 24.11 SOFTWARE USE OF THE VMCS AND RELATED STRUCTURES

This section details guidelines that software should observe when using a VMCS and related structures. It also provides descriptions of consequences for failing to follow guidelines.

## 24.11.1 Software Use of Virtual-Machine Control Structures

To ensure proper processor behavior, software should observe certain guidelines when using an active VMCS.

No VMCS should ever be active on more than one logical processor. If a VMCS is to be "migrated" from one logical processor to another, the first logical processor should execute VMCLEAR for the VMCS (to make it inactive on that logical processor and to ensure that all VMCS data are in memory) before the other logical processor executes VMPTRLD for the VMCS (to make it active on the second logical processor).[1] A VMCS that is made active on more than one logical processor may become **corrupted** (see below).

Software should not modify the shadow-VMCS indicator (see Table 24-1) in the VMCS region of a VMCS that is active. Doing so may cause the VMCS to become corrupted. Before modifying the shadow-VMCS indicator, software should execute VMCLEAR for the VMCS to ensure that it is not active.

Software should use the VMREAD and VMWRITE instructions to access the different fields in the current VMCS (see Section 24.11.2). Software should never access or modify the VMCS data of an active VMCS using ordinary memory operations, in part because the format used to store the VMCS data is implementation-specific and not architecturally defined, and also because a logical processor may maintain some VMCS data of an active VMCS on the processor and not in the VMCS region. The following items detail some of the hazards of accessing VMCS data using ordinary memory operations:

- Any data read from a VMCS with an ordinary memory read does not reliably reflect the state of the VMCS. Results may vary from time to time or from logical processor to logical processor.
- Writing to a VMCS with an ordinary memory write is not guaranteed to have a deterministic effect on the VMCS. Doing so may cause the VMCS to become corrupted (see below).

(Software can avoid these hazards by removing any linear-address mappings to a VMCS region before executing a VMPTRLD for that region and by not remapping it until after executing VMCLEAR for that region.)

If a logical processor leaves VMX operation, any VMCSs active on that logical processor may be corrupted (see below). To prevent such corruption of a VMCS that may be used either after a return to VMX operation or on another logical processor, software should execute VMCLEAR for that VMCS before executing the VMXOFF instruction or removing power from the processor (e.g., as part of a transition to the S3 and S4 power states).

This section has identified operations that may cause a VMCS to become corrupted. These operations may cause the VMCS's data to become undefined. Behavior may be unpredictable if that VMCS used subsequently on any logical processor. The following items detail some hazards of VMCS corruption:

- VM entries may fail for unexplained reasons or may load undesired processor state.
- The processor may not correctly support VMX non-root operation as documented in Chapter 27 and may generate unexpected VM exits.
- VM exits may load undesired processor state, save incorrect state into the VMCS, or cause the logical processor to transition to a shutdown state.

## 24.11.2 VMREAD, VMWRITE, and Encodings of VMCS Fields

Every field of the VMCS is associated with a 32-bit value that is its **encoding**. The encoding is provided in an operand to VMREAD and VMWRITE when software wishes to read or write that field. These instructions fail if given, in 64-bit mode, an operand that sets an encoding bit beyond bit 32. See Chapter 30 for a description of these instructions.

---

1. As noted in Section 24.1, execution of the VMPTRLD instruction makes a VMCS is active. In addition, VM entry makes active any shadow VMCS referenced by the VMCS link pointer in the current VMCS. If a shadow VMCS is made active by VM entry, it is necessary to execute VMCLEAR for that VMCS before allowing that VMCS to become active on another logical processor.

The structure of the 32-bit encodings of the VMCS components is determined principally by the width of the fields and their function in the VMCS. See Table 24-17.

**Table 24-17. Structure of VMCS Component Encoding**

| Bit Position(s) | Contents |
|---|---|
| 0 | Access type (0 = full; 1 = high); must be full for 16-bit, 32-bit, and natural-width fields |
| 9:1 | Index |
| 11:10 | Type:<br>0: control<br>1: VM-exit information<br>2: guest state<br>3: host state |
| 12 | Reserved (must be 0) |
| 14:13 | Width:<br>0: 16-bit<br>1: 64-bit<br>2: 32-bit<br>3: natural-width |
| 31:15 | Reserved (must be 0) |

The following items detail the meaning of the bits in each encoding:

- **Field width.** Bits 14:13 encode the width of the field.
  - A value of 0 indicates a 16-bit field.
  - A value of 1 indicates a 64-bit field.
  - A value of 2 indicates a 32-bit field.
  - A value of 3 indicates a **natural-width** field. Such fields have 64 bits on processors that support Intel 64 architecture and 32 bits on processors that do not.

  Fields whose encodings use value 1 are specially treated to allow 32-bit software access to all 64 bits of the field. Such access is allowed by defining, for each such field, an encoding that allows direct access to the high 32 bits of the field. See below.
- **Field type.** Bits 11:10 encode the type of VMCS field: control, guest-state, host-state, or VM-exit information. (The last category also includes the VM-instruction error field.)
- **Index.** Bits 9:1 distinguish components with the same field width and type.
- **Access type.** Bit 0 must be 0 for all fields except for 64-bit fields (those with field-width 1; see above). A VMREAD or VMWRITE using an encoding with this bit cleared to 0 accesses the entire field. For a 64-bit field with field-width 1, a VMREAD or VMWRITE using an encoding with this bit set to 1 accesses only the high 32 bits of the field.

Appendix B gives the encodings of all fields in the VMCS.

The following describes the operation of VMREAD and VMWRITE based on processor mode, VMCS-field width, and access type:

- 16-bit fields:
  - A VMREAD returns the value of the field in bits 15:0 of the destination operand; other bits of the destination operand are cleared to 0.
  - A VMWRITE writes the value of bits 15:0 of the source operand into the VMCS field; other bits of the source operand are not used.
- 32-bit fields:

  - A VMREAD returns the value of the field in bits 31:0 of the destination operand; in 64-bit mode, bits 63:32 of the destination operand are cleared to 0.
  - A VMWRITE writes the value of bits 31:0 of the source operand into the VMCS field; in 64-bit mode, bits 63:32 of the source operand are not used.
- 64-bit fields and natural-width fields using the full access type outside IA-32e mode.
  - A VMREAD returns the value of bits 31:0 of the field in its destination operand; bits 63:32 of the field are ignored.
  - A VMWRITE writes the value of its source operand to bits 31:0 of the field and clears bits 63:32 of the field.
- 64-bit fields and natural-width fields using the full access type in 64-bit mode (only on processors that support Intel 64 architecture).
  - A VMREAD returns the value of the field in bits 63:0 of the destination operand
  - A VMWRITE writes the value of bits 63:0 of the source operand into the VMCS field.
- 64-bit fields using the high access type.
  - A VMREAD returns the value of bits 63:32 of the field in bits 31:0 of the destination operand; in 64-bit mode, bits 63:32 of the destination operand are cleared to 0.
  - A VMWRITE writes the value of bits 31:0 of the source operand to bits 63:32 of the field; in 64-bit mode, bits 63:32 of the source operand are not used.

Software seeking to read a 64-bit field outside IA-32e mode can use VMREAD with the full access type (reading bits 31:0 of the field) and VMREAD with the high access type (reading bits 63:32 of the field); the order of the two VMREAD executions is not important. Software seeking to modify a 64-bit field outside IA-32e mode should first use VMWRITE with the full access type (establishing bits 31:0 of the field while clearing bits 63:32) and then use VMWRITE with the high access type (establishing bits 63:32 of the field).

### 24.11.3 Initializing a VMCS

Software should initialize fields in a VMCS (using VMWRITE) before using the VMCS for VM entry. Failure to do so may result in unpredictable behavior; for example, a VM entry may fail for unexplained reasons, or a successful transition (VM entry or VM exit) may load processor state with unexpected values.

It is not necessary to initialize fields that the logical processor will not use. (For example, it is not necessary to unitize the MSR-bitmap address if the “use MSR bitmaps” VM-execution control is 0.)

A processor maintains some VMCS information that cannot be modified with the VMWRITE instruction; this includes a VMCS’s launch state (see Section 24.1). Such information may be stored in the VMCS data portion of a VMCS region. Because the format of this information is implementation-specific, there is no way for software to know, when it first allocates a region of memory for use as a VMCS region, how the processor will determine this information from the contents of the memory region.

In addition to its other functions, the VMCLEAR instruction initializes any implementation-specific information in the VMCS region referenced by its operand. To avoid the uncertainties of implementation-specific behavior, software should execute VMCLEAR on a VMCS region before making the corresponding VMCS active with VMPTRLD for the first time. (Figure 24-1 illustrates how execution of VMCLEAR puts a VMCS into a well-defined state.)

The following software usage is consistent with these limitations:

- VMCLEAR should be executed for a VMCS before it is used for VM entry for the first time.
- VMLAUNCH should be used for the first VM entry using a VMCS after VMCLEAR has been executed for that VMCS.
- VMRESUME should be used for any subsequent VM entry using a VMCS (until the next execution of VMCLEAR for the VMCS).

It is expected that, in general, VMRESUME will have lower latency than VMLAUNCH. Since “migrating” a VMCS from one logical processor to another requires use of VMCLEAR (see Section 24.11.1), which sets the launch state of the VMCS to “clear”, such migration requires the next VM entry to be performed using VMLAUNCH. Software developers can avoid the performance cost of increased VM-entry latency by avoiding unnecessary migration of a VMCS from one logical processor to another.

### 24.11.4 Software Access to Related Structures

In addition to data in the VMCS region itself, VMX non-root operation can be controlled by data structures that are referenced by pointers in a VMCS (for example, the I/O bitmaps). While the pointers to these data structures are parts of the VMCS, the data structures themselves are not. They are not accessible using VMREAD and VMWRITE but by ordinary memory writes.

Software should ensure that each such data structure is modified only when no logical processor with a current VMCS that references it is in VMX non-root operation. Doing otherwise may lead to unpredictable behavior (including behaviors identified in Section 24.11.1).

### 24.11.5 VMXON Region

Before executing VMXON, software allocates a region of memory (called the VMXON region)[1] that the logical processor uses to support VMX operation. The physical address of this region (the VMXON pointer) is provided in an operand to VMXON. The VMXON pointer is subject to the limitations that apply to VMCS pointers:

- The VMXON pointer must be 4-KByte aligned (bits 11:0 must be zero).
- The VMXON pointer must not set any bits beyond the processor's physical-address width.[2,3]

Before executing VMXON, software should write the VMCS revision identifier (see Section 24.2) to the VMXON region. (Specifically, it should write the 31-bit VMCS revision identifier to bits 30:0 of the first 4 bytes of the VMXON region; bit 31 should be cleared to 0.) It need not initialize the VMXON region in any other way. Software should use a separate region for each logical processor and should not access or modify the VMXON region of a logical processor between execution of VMXON and VMXOFF on that logical processor. Doing otherwise may lead to unpredictable behavior (including behaviors identified in Section 24.11.1).

1. The amount of memory required for the VMXON region is the same as that required for a VMCS region. This size is implementation specific and can be determined by consulting the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1).
2. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
3. If IA32_VMX_BASIC[48] is read as 1, the VMXON pointer must not set any bits in the range 63:32; see Appendix A.1.

# CHAPTER 25
# VMX NON-ROOT OPERATION

In a virtualized environment using VMX, the guest software stack typically runs on a logical processor in VMX non-root operation. This mode of operation is similar to that of ordinary processor operation outside of the virtualized environment. This chapter describes the differences between VMX non-root operation and ordinary processor operation with special attention to causes of VM exits (which bring a logical processor from VMX non-root operation to root operation). The differences between VMX non-root operation and ordinary processor operation are described in the following sections:

- Section 25.1, "Instructions That Cause VM Exits"
- Section 25.2, "Other Causes of VM Exits"
- Section 25.3, "Changes to Instruction Behavior in VMX Non-Root Operation"
- Section 25.4, "Other Changes in VMX Non-Root Operation"
- Section 25.5, "Features Specific to VMX Non-Root Operation"
- Section 25.6, "Unrestricted Guests"

Chapter 26, "VM Entries," describes the data control structures that govern VMX non-root operation. Chapter 26, "VM Entries," describes the operation of VM entries by which the processor transitions from VMX root operation to VMX non-root operation. Chapter 25, "VMX Non-Root Operation," describes the operation of VM exits by which the processor transitions from VMX non-root operation to VMX root operation.

Chapter 28, "VMX Support for Address Translation," describes two features that support address translation in VMX non-root operation. Chapter 29, "APIC Virtualization and Virtual Interrupts," describes features that support virtualization of interrupts and the Advanced Programmable Interrupt Controller (APIC) in VMX non-root operation.

## 25.1 INSTRUCTIONS THAT CAUSE VM EXITS

Certain instructions may cause VM exits if executed in VMX non-root operation. Unless otherwise specified, such VM exits are "fault-like," meaning that the instruction causing the VM exit does not execute and no processor state is updated by the instruction. Section 27.1 details architectural state in the context of a VM exit.

Section 25.1.1 defines the prioritization between faults and VM exits for instructions subject to both. Section 25.1.2 identifies instructions that cause VM exits whenever they are executed in VMX non-root operation (and thus can never be executed in VMX non-root operation). Section 25.1.3 identifies instructions that cause VM exits depending on the settings of certain VM-execution control fields (see Section 24.6).

### 25.1.1 Relative Priority of Faults and VM Exits

The following principles describe the ordering between existing faults and VM exits:

- Certain exceptions have priority over VM exits. These include invalid-opcode exceptions, faults based on privilege level,[1] and general-protection exceptions that are based on checking I/O permission bits in the task-state segment (TSS). For example, execution of RDMSR with CPL = 3 generates a general-protection exception and not a VM exit.[2]
- Faults incurred while fetching instruction operands have priority over VM exits that are conditioned based on the contents of those operands (see LMSW in Section 25.1.3).
- VM exits caused by execution of the INS and OUTS instructions (resulting either because the "unconditional I/O exiting" VM-execution control is 1 or because the "use I/O bitmaps control is 1) have priority over the following faults:

1. These include faults generated by attempts to execute, in virtual-8086 mode, privileged instructions that are not recognized in that mode.
2. MOV DR is an exception to this rule; see Section 25.1.3.

  - A general-protection fault due to the relevant segment (ES for INS; DS for OUTS unless overridden by an instruction prefix) being unusable
  - A general-protection fault due to an offset beyond the limit of the relevant segment
  - An alignment-check exception
- Fault-like VM exits have priority over exceptions other than those mentioned above. For example, RDMSR of a non-existent MSR with CPL = 0 generates a VM exit and not a general-protection exception.

When Section 25.1.2 or Section 25.1.3 (below) identify an instruction execution that may lead to a VM exit, it is assumed that the instruction does not incur a fault that takes priority over a VM exit.

### 25.1.2 Instructions That Cause VM Exits Unconditionally

The following instructions cause VM exits when they are executed in VMX non-root operation: CPUID, GETSEC,[1] INVD, and XSETBV. This is also true of instructions introduced with VMX, which include: INVEPT, INVVPID, VMCALL,[2] VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMRESUME, VMXOFF, and VMXON.

### 25.1.3 Instructions That Cause VM Exits Conditionally

Certain instructions cause VM exits in VMX non-root operation depending on the setting of the VM-execution controls. The following instructions can cause "fault-like" VM exits based on the conditions described:[3]

- **CLTS**. The CLTS instruction causes a VM exit if the bits in position 3 (corresponding to CR0.TS) are set in both the CR0 guest/host mask and the CR0 read shadow.
- **HLT.** The HLT instruction causes a VM exit if the "HLT exiting" VM-execution control is 1.
- **IN, INS/INSB/INSW/INSD, OUT, OUTS/OUTSB/OUTSW/OUTSD.** The behavior of each of these instructions is determined by the settings of the "unconditional I/O exiting" and "use I/O bitmaps" VM-execution controls:
  - If both controls are 0, the instruction executes normally.
  - If the "unconditional I/O exiting" VM-execution control is 1 and the "use I/O bitmaps" VM-execution control is 0, the instruction causes a VM exit.
  - If the "use I/O bitmaps" VM-execution control is 1, the instruction causes a VM exit if it attempts to access an I/O port corresponding to a bit set to 1 in the appropriate I/O bitmap (see Section 24.6.4). If an I/O operation "wraps around" the 16-bit I/O-port space (accesses ports FFFFH and 0000H), the I/O instruction causes a VM exit (the "unconditional I/O exiting" VM-execution control is ignored if the "use I/O bitmaps" VM-execution control is 1).

  See Section 25.1.1 for information regarding the priority of VM exits relative to faults that may be caused by the INS and OUTS instructions.
- **INVLPG.** The INVLPG instruction causes a VM exit if the "INVLPG exiting" VM-execution control is 1.
- **INVPCID.** The INVPCID instruction causes a VM exit if the "INVLPG exiting" and "enable INVPCID" VM-execution controls are both 1.
- **LGDT, LIDT, LLDT, LTR, SGDT, SIDT, SLDT, STR.** These instructions cause VM exits if the "descriptor-table exiting" VM-execution control is 1.
- **LMSW.** In general, the LMSW instruction causes a VM exit if it would write, for any bit set in the low 4 bits of the CR0 guest/host mask, a value different than the corresponding bit in the CR0 read shadow. LMSW never clears bit 0 of CR0 (CR0.PE); thus, LMSW causes a VM exit if either of the following are true:

1. An execution of GETSEC in VMX non-root operation causes a VM exit if CR4.SMXE[Bit 14] = 1 regardless of the value of CPL or RAX. An execution of GETSEC causes an invalid-opcode exception (#UD) if CR4.SMXE[Bit 14] = 0.
2. Under the dual-monitor treatment of SMIs and SMM, executions of VMCALL cause SMM VM exits in VMX root operation outside SMM. See Section 34.15.2.
3. Many of the items in this section refer to secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if these controls were all 0. See Section 24.6.2.

— The bits in position 0 (corresponding to CR0.PE) are set in both the CR0 guest/mask and the source operand, and the bit in position 0 is clear in the CR0 read shadow.

— For any bit position in the range 3:1, the bit in that position is set in the CR0 guest/mask and the values of the corresponding bits in the source operand and the CR0 read shadow differ.

- **MONITOR.** The MONITOR instruction causes a VM exit if the "MONITOR exiting" VM-execution control is 1.
- **MOV from CR3.** The MOV from CR3 instruction causes a VM exit if the "CR3-store exiting" VM-execution control is 1. The first processors to support the virtual-machine extensions supported only the 1-setting of this control.
- **MOV from CR8.** The MOV from CR8 instruction causes a VM exit if the "CR8-store exiting" VM-execution control is 1.
- **MOV to CR0.** The MOV to CR0 instruction causes a VM exit unless the value of its source operand matches, for the position of each bit set in the CR0 guest/host mask, the corresponding bit in the CR0 read shadow. (If every bit is clear in the CR0 guest/host mask, MOV to CR0 cannot cause a VM exit.)
- **MOV to CR3.** The MOV to CR3 instruction causes a VM exit unless the "CR3-load exiting" VM-execution control is 0 or the value of its source operand is equal to one of the CR3-target values specified in the VMCS. If the CR3-target count in *n*, only the first *n* CR3-target values are considered; if the CR3-target count is 0, MOV to CR3 always causes a VM exit.

  The first processors to support the virtual-machine extensions supported only the 1-setting of the "CR3-load exiting" VM-execution control. These processors always consult the CR3-target controls to determine whether an execution of MOV to CR3 causes a VM exit.
- **MOV to CR4.** The MOV to CR4 instruction causes a VM exit unless the value of its source operand matches, for the position of each bit set in the CR4 guest/host mask, the corresponding bit in the CR4 read shadow.
- **MOV to CR8.** The MOV to CR8 instruction causes a VM exit if the "CR8-load exiting" VM-execution control is 1.
- **MOV DR.** The MOV DR instruction causes a VM exit if the "MOV-DR exiting" VM-execution control is 1. Such VM exits represent an exception to the principles identified in Section 25.1.1 in that they take priority over the following: general-protection exceptions based on privilege level; and invalid-opcode exceptions that occur because CR4.DE=1 and the instruction specified access to DR4 or DR5.
- **MWAIT.** The MWAIT instruction causes a VM exit if the "MWAIT exiting" VM-execution control is 1. If this control is 0, the behavior of the MWAIT instruction may be modified (see Section 25.3).
- **PAUSE.**The behavior of each of this instruction depends on CPL and the settings of the "PAUSE exiting" and "PAUSE-loop exiting" VM-execution controls**:**

  — CPL = 0.

    - If the "PAUSE exiting" and "PAUSE-loop exiting" VM-execution controls are both 0, the PAUSE instruction executes normally.
    - If the "PAUSE exiting" VM-execution control is 1, the PAUSE instruction causes a VM exit (the "PAUSE-loop exiting" VM-execution control is ignored if CPL = 0 and the "PAUSE exiting" VM-execution control is 1).
    - If the "PAUSE exiting" VM-execution control is 0 and the "PAUSE-loop exiting" VM-execution control is 1, the following treatment applies.

      The processor determines the amount of time between this execution of PAUSE and the previous execution of PAUSE at CPL 0. If this amount of time exceeds the value of the VM-execution control field PLE_Gap, the processor considers this execution to be the first execution of PAUSE in a loop. (It also does so for the first execution of PAUSE at CPL 0 after VM entry.)

      Otherwise, the processor determines the amount of time since the most recent execution of PAUSE that was considered to be the first in a loop. If this amount of time exceeds the value of the VM-execution control field PLE_Window, a VM exit occurs.

      For purposes of these computations, time is measured based on a counter that runs at the same rate as the timestamp counter (TSC).

  — CPL > 0.

    - If the "PAUSE exiting" VM-execution control is 0, the PAUSE instruction executes normally.

  - If the "PAUSE exiting" VM-execution control is 1, the PAUSE instruction causes a VM exit.

  The "PAUSE-loop exiting" VM-execution control is ignored if CPL > 0.
- **RDMSR.** The RDMSR instruction causes a VM exit if any of the following are true:
  — The "use MSR bitmaps" VM-execution control is 0.
  — The value of ECX is not in the ranges 00000000H – 00001FFFH and C0000000H – C0001FFFH.
  — The value of ECX is in the range 00000000H – 00001FFFH and bit *n* in read bitmap for low MSRs is 1, where *n* is the value of ECX.
  — The value of ECX is in the range C0000000H – C0001FFFH and bit *n* in read bitmap for high MSRs is 1, where *n* is the value of ECX & 00001FFFH.

  See Section 24.6.9 for details regarding how these bitmaps are identified.
- **RDPMC.** The RDPMC instruction causes a VM exit if the "RDPMC exiting" VM-execution control is 1.
- **RDRAND.** The RDRAND instruction causes a VM exit if the "RDRAND exiting" VM-execution control is 1.
- **RDSEED.** The RDSEED instruction causes a VM exit if the "RDSEED exiting" VM-execution control is 1.
- **RDTSC.** The RDTSC instruction causes a VM exit if the "RDTSC exiting" VM-execution control is 1.
- **RDTSCP.** The RDTSCP instruction causes a VM exit if the "RDTSC exiting" and "enable RDTSCP" VM-execution controls are both 1.
- **RSM.** The RSM instruction causes a VM exit if executed in system-management mode (SMM).[1]
- **VMREAD.** The VMREAD instruction causes a VM exit if any of the following are true:
  — The "VMCS shadowing" VM-execution control is 0.
  — Bits 63:15 (bits 31:15 outside 64-bit mode) of the register source operand are not all 0.
  — Bit *n* in VMREAD bitmap is 1, where *n* is the value of bits 14:0 of the register source operand. See Section 24.6.15 for details regarding how the VMREAD bitmap is identified.

  If the VMREAD instruction does not cause a VM exit, it reads from the VMCS referenced by the VMCS link pointer. See Chapter 30, "VMREAD—Read Field from Virtual-Machine Control Structure" for details of the operation of the VMREAD instruction.
- **VMWRITE.** The VMWRITE instruction causes a VM exit if any of the following are true:
  — The "VMCS shadowing" VM-execution control is 0.
  — Bits 63:15 (bits 31:15 outside 64-bit mode) of the register source operand are not all 0.
  — Bit *n* in VMWRITE bitmap is 1, where *n* is the value of bits 14:0 of the register source operand. See Section 24.6.15 for details regarding how the VMWRITE bitmap is identified.

  If the VMWRITE instruction does not cause a VM exit, it writes to the VMCS referenced by the VMCS link pointer. See Chapter 30, "VMWRITE—Write Field to Virtual-Machine Control Structure" for details of the operation of the VMWRITE instruction.
- **WBINVD.** The WBINVD instruction causes a VM exit if the "WBINVD exiting" VM-execution control is 1.
- **WRMSR.** The WRMSR instruction causes a VM exit if any of the following are true:
  — The "use MSR bitmaps" VM-execution control is 0.
  — The value of ECX is not in the ranges 00000000H – 00001FFFH and C0000000H – C0001FFFH.
  — The value of ECX is in the range 00000000H – 00001FFFH and bit *n* in write bitmap for low MSRs is 1, where *n* is the value of ECX.
  — The value of ECX is in the range C0000000H – C0001FFFH and bit *n* in write bitmap for high MSRs is 1, where *n* is the value of ECX & 00001FFFH.

  See Section 24.6.9 for details regarding how these bitmaps are identified.

1. Execution of the RSM instruction outside SMM causes an invalid-opcode exception regardless of whether the processor is in VMX operation. It also does so in VMX root operation in SMM; see Section 34.15.3.

- **XRSTORS.** The XRSTORS instruction causes a VM exit if the "enable XSAVES/XRSTORS" VM-execution control is 1and any bit is set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap (see Section 24.6.17).
- **XSAVES.** The XSAVES instruction causes a VM exit if the "enable XSAVES/XRSTORS" VM-execution control is 1and any bit is set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap (see Section 24.6.17).

## 25.2 OTHER CAUSES OF VM EXITS

In addition to VM exits caused by instruction execution, the following events can cause VM exits:

- **Exceptions.** Exceptions (faults, traps, and aborts) cause VM exits based on the exception bitmap (see Section 24.6.3). If an exception occurs, its vector (in the range 0–31) is used to select a bit in the exception bitmap. If the bit is 1, a VM exit occurs; if the bit is 0, the exception is delivered normally through the guest IDT. This use of the exception bitmap applies also to exceptions generated by the instructions INT3, INTO, BOUND, and UD2.

  Page faults (exceptions with vector 14) are specially treated. When a page fault occurs, a processor consults (1) bit 14 of the exception bitmap; (2) the error code produced with the page fault [PFEC]; (3) the page-fault error-code mask field [PFEC_MASK]; and (4) the page-fault error-code match field [PFEC_MATCH]. It checks if PFEC & PFEC_MASK = PFEC_MATCH. If there is equality, the specification of bit 14 in the exception bitmap is followed (for example, a VM exit occurs if that bit is set). If there is inequality, the meaning of that bit is reversed (for example, a VM exit occurs if that bit is clear).

  Thus, if software desires VM exits on all page faults, it can set bit 14 in the exception bitmap to 1 and set the page-fault error-code mask and match fields each to 00000000H. If software desires VM exits on no page faults, it can set bit 14 in the exception bitmap to 1, the page-fault error-code mask field to 00000000H, and the page-fault error-code match field to FFFFFFFFH.
- **Triple fault.** A VM exit occurs if the logical processor encounters an exception while attempting to call the double-fault handler and that exception itself does not cause a VM exit due to the exception bitmap. This applies to the case in which the double-fault exception was generated within VMX non-root operation, the case in which the double-fault exception was generated during event injection by VM entry, and to the case in which VM entry is injecting a double-fault exception.
- **External interrupts.** An external interrupt causes a VM exit if the "external-interrupt exiting" VM-execution control is 1. Otherwise, the interrupt is delivered normally through the IDT. (If a logical processor is in the shutdown state or the wait-for-SIPI state, external interrupts are blocked. The interrupt is not delivered through the IDT and no VM exit occurs.)
- **Non-maskable interrupts (NMIs).** An NMI causes a VM exit if the "NMI exiting" VM-execution control is 1. Otherwise, it is delivered using descriptor 2 of the IDT. (If a logical processor is in the wait-for-SIPI state, NMIs are blocked. The NMI is not delivered through the IDT and no VM exit occurs.)
- **INIT signals.** INIT signals cause VM exits. A logical processor performs none of the operations normally associated with these events. Such exits do not modify register state or clear pending events as they would outside of VMX operation. (If a logical processor is in the wait-for-SIPI state, INIT signals are blocked. They do not cause VM exits in this case.)
- **Start-up IPIs (SIPIs). SIPIs cause VM exits.** If a logical processor is not in the wait-for-SIPI activity state when a SIPI arrives, no VM exit occurs and the SIPI is discarded. VM exits due to SIPIs do not perform any of the normal operations associated with those events: they do not modify register state as they would outside of VMX operation. (If a logical processor is not in the wait-for-SIPI state, SIPIs are blocked. They do not cause VM exits in this case.)
- **Task switches.** Task switches are not allowed in VMX non-root operation. Any attempt to effect a task switch in VMX non-root operation causes a VM exit. See Section 25.4.2.
- **System-management interrupts (SMIs).** If the logical processor is using the dual-monitor treatment of SMIs and system-management mode (SMM), SMIs cause SMM VM exits. See Section 34.15.2.[1]

1. Under the dual-monitor treatment of SMIs and SMM, SMIs also cause SMM VM exits if they occur in VMX root operation outside SMM. If the processor is using the default treatment of SMIs and SMM, SMIs are delivered as described in Section 34.14.1.

- **VMX-preemption timer.** A VM exit occurs when the timer counts down to zero. See Section 25.5.1 for details of operation of the VMX-preemption timer.

  Debug-trap exceptions and higher priority events take priority over VM exits caused by the VMX-preemption timer. VM exits caused by the VMX-preemption timer take priority over VM exits caused by the "NMI-window exiting" VM-execution control and lower priority events.

  These VM exits wake a logical processor from the same inactive states as would a non-maskable interrupt. Specifically, they wake a logical processor from the shutdown state and from the states entered using the HLT and MWAIT instructions. These VM exits do not occur if the logical processor is in the wait-for-SIPI state.

In addition, there are controls that cause VM exits based on the readiness of guest software to receive interrupts:

- If the "interrupt-window exiting" VM-execution control is 1, a VM exit occurs before execution of any instruction if RFLAGS.IF = 1 and there is no blocking of events by STI or by MOV SS (see Table 24-3). Such a VM exit occurs immediately after VM entry if the above conditions are true (see Section 26.6.5).

  Non-maskable interrupts (NMIs) and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over external interrupts and lower priority events.

  These VM exits wake a logical processor from the same inactive states as would an external interrupt. Specifically, they wake a logical processor from the states entered using the HLT and MWAIT instructions. These VM exits do not occur if the logical processor is in the shutdown state or the wait-for-SIPI state.
- If the "NMI-window exiting" VM-execution control is 1, a VM exit occurs before execution of any instruction if there is no virtual-NMI blocking and there is no blocking of events by MOV SS (see Table 24-3). (A logical processor may also prevent such a VM exit if there is blocking of events by STI.) Such a VM exit occurs immediately after VM entry if the above conditions are true (see Section 26.6.6).

  VM exits caused by the VMX-preemption timer and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over non-maskable interrupts (NMIs) and lower priority events.

  These VM exits wake a logical processor from the same inactive states as would an NMI. Specifically, they wake a logical processor from the shutdown state and from the states entered using the HLT and MWAIT instructions. These VM exits do not occur if the logical processor is in the wait-for-SIPI state.

## 25.3 CHANGES TO INSTRUCTION BEHAVIOR IN VMX NON-ROOT OPERATION

The behavior of some instructions is changed in VMX non-root operation. Some of these changes are determined by the settings of certain VM-execution control fields. The following items detail such changes:[1]

- **CLTS.** Behavior of the CLTS instruction is determined by the bits in position 3 (corresponding to CR0.TS) in the CR0 guest/host mask and the CR0 read shadow:
  - If bit 3 in the CR0 guest/host mask is 0, CLTS clears CR0.TS normally (the value of bit 3 in the CR0 read shadow is irrelevant in this case), unless CR0.TS is fixed to 1 in VMX operation (see Section 23.8), in which case CLTS causes a general-protection exception.
  - If bit 3 in the CR0 guest/host mask is 1 and bit 3 in the CR0 read shadow is 0, CLTS completes but does not change the contents of CR0.TS.
  - If the bits in position 3 in the CR0 guest/host mask and the CR0 read shadow are both 1, CLTS causes a VM exit.
- **INVPCID.** Behavior of the INVPCID instruction is determined first by the setting of the "enable INVPCID" VM-execution control:
  - If the "enable INVPCID" VM-execution control is 0, INVPCID causes an invalid-opcode exception (#UD).
  - If the "enable INVPCID" VM-execution control is 1, treatment is based on the setting of the "INVLPG exiting" VM-execution control:
    - If the "INVLPG exiting" VM-execution control is 0, INVPCID operates normally.

1. Some of the items in this section refer to secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if these controls were all 0. See Section 24.6.2.

  - If the "INVLPG exiting" VM-execution control is 1, INVPCID causes a VM exit.

- **IRET.** Behavior of IRET with regard to NMI blocking (see Table 24-3) is determined by the settings of the "NMI exiting" and "virtual NMIs" VM-execution controls:
  - If the "NMI exiting" VM-execution control is 0, IRET operates normally and unblocks NMIs. (If the "NMI exiting" VM-execution control is 0, the "virtual NMIs" control must be 0; see Section 26.2.1.1.)
  - If the "NMI exiting" VM-execution control is 1, IRET does not affect blocking of NMIs. If, in addition, the "virtual NMIs" VM-execution control is 1, the logical processor tracks virtual-NMI blocking. In this case, IRET removes any virtual-NMI blocking.

  The unblocking of NMIs or virtual NMIs specified above occurs even if IRET causes a fault.
- **LMSW.** Outside of VMX non-root operation, LMSW loads its source operand into CR0[3:0], but it does not clear CR0.PE if that bit is set. In VMX non-root operation, an execution of LMSW that does not cause a VM exit (see Section 25.1.3) leaves unmodified any bit in CR0[3:0] corresponding to a bit set in the CR0 guest/host mask. An attempt to set any other bit in CR0[3:0] to a value not supported in VMX operation (see Section 23.8) causes a general-protection exception. Attempts to clear CR0.PE are ignored without fault.
- **MOV from CR0.** The behavior of MOV from CR0 is determined by the CR0 guest/host mask and the CR0 read shadow. For each position corresponding to a bit clear in the CR0 guest/host mask, the destination operand is loaded with the value of the corresponding bit in CR0. For each position corresponding to a bit set in the CR0 guest/host mask, the destination operand is loaded with the value of the corresponding bit in the CR0 read shadow. Thus, if every bit is cleared in the CR0 guest/host mask, MOV from CR0 reads normally from CR0; if every bit is set in the CR0 guest/host mask, MOV from CR0 returns the value of the CR0 read shadow.

  Depending on the contents of the CR0 guest/host mask and the CR0 read shadow, bits may be set in the destination that would never be set when reading directly from CR0.
- **MOV from CR3.** If the "enable EPT" VM-execution control is 1 and an execution of MOV from CR3 does not cause a VM exit (see Section 25.1.3), the value loaded from CR3 is a guest-physical address; see Section 28.2.1.
- **MOV from CR4.** The behavior of MOV from CR4 is determined by the CR4 guest/host mask and the CR4 read shadow. For each position corresponding to a bit clear in the CR4 guest/host mask, the destination operand is loaded with the value of the corresponding bit in CR4. For each position corresponding to a bit set in the CR4 guest/host mask, the destination operand is loaded with the value of the corresponding bit in the CR4 read shadow. Thus, if every bit is cleared in the CR4 guest/host mask, MOV from CR4 reads normally from CR4; if every bit is set in the CR4 guest/host mask, MOV from CR4 returns the value of the CR4 read shadow.

  Depending on the contents of the CR4 guest/host mask and the CR4 read shadow, bits may be set in the destination that would never be set when reading directly from CR4.
- **MOV from CR8.** If the MOV from CR8 instruction does not cause a VM exit (see Section 25.1.3), its behavior is modified if the "use TPR shadow" VM-execution control is 1; see Section 29.3.
- **MOV to CR0.** An execution of MOV to CR0 that does not cause a VM exit (see Section 25.1.3) leaves unmodified any bit in CR0 corresponding to a bit set in the CR0 guest/host mask. Treatment of attempts to modify other bits in CR0 depends on the setting of the "unrestricted guest" VM-execution control:
  - If the control is 0, MOV to CR0 causes a general-protection exception if it attempts to set any bit in CR0 to a value not supported in VMX operation (see Section 23.8).
  - If the control is 1, MOV to CR0 causes a general-protection exception if it attempts to set any bit in CR0 other than bit 0 (PE) or bit 31 (PG) to a value not supported in VMX operation. It remains the case, however, that MOV to CR0 causes a general-protection exception if it would result in CR0.PE = 0 and CR0.PG = 1 or if it would result in CR0.PG = 1, CR4.PAE = 0, and IA32_EFER.LME = 1.
- **MOV to CR3.** If the "enable EPT" VM-execution control is 1 and an execution of MOV to CR3 does not cause a VM exit (see Section 25.1.3), the value loaded into CR3 is treated as a guest-physical address; see Section 28.2.1.
  - If PAE paging is not being used, the instruction does not use the guest-physical address to access memory and it does not cause it to be translated through EPT.[1]

1. A logical processor uses PAE paging if CR0.PG = 1, CR4.PAE = 1 and IA32_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

  - If PAE paging is being used, the instruction translates the guest-physical address through EPT and uses the result to load the four (4) page-directory-pointer-table entries (PDPTEs). The instruction does not use the guest-physical addresses the PDPTEs to access memory and it does not cause them to be translated through EPT.

- **MOV to CR4.** An execution of MOV to CR4 that does not cause a VM exit (see Section 25.1.3) leaves unmodified any bit in CR4 corresponding to a bit set in the CR4 guest/host mask. Such an execution causes a general-protection exception if it attempts to set any bit in CR4 (not corresponding to a bit set in the CR4 guest/host mask) to a value not supported in VMX operation (see Section 23.8).
- **MOV to CR8.** If the MOV **to** CR8 instruction does not cause a VM exit (see Section 25.1.3), its behavior is modified if the "use TPR shadow" VM-execution control is 1; see Section 29.3.
- **MWAIT.** Behavior of the MWAIT instruction (which always causes an invalid-opcode exception—#UD—if CPL > 0) is determined by the setting of the "MWAIT exiting" VM-execution control:
  - If the "MWAIT exiting" VM-execution control is 1, MWAIT causes a VM exit.
  - If the "MWAIT exiting" VM-execution control is 0, MWAIT operates normally if one of the following are true: (1) ECX[0] is 0; (2) RFLAGS.IF = 1; or both of the following are true: (a) the "interrupt-window exiting" VM-execution control is 0; and (b) the logical processor has not recognized a pending virtual interrupt (see Section 29.2.1).
  - If the "MWAIT exiting" VM-execution control is 0, ECX[0] = 1, and RFLAGS.IF = 0, MWAIT does not cause the processor to enter an implementation-dependent optimized state if either the "interrupt-window exiting" VM-execution control is 1 or the logical processor has recognized a pending virtual interrupt; instead, control passes to the instruction following the MWAIT instruction.
- **RDMSR.** Section 25.1.3 identifies when executions of the RDMSR instruction cause VM exits. If such an execution causes neither a fault due to CPL > 0 nor a VM exit, the instruction's behavior may be modified for certain values of ECX:
  - If ECX contains 10H (indicating the IA32_TIME_STAMP_COUNTER MSR), the value returned by the instruction is determined by the setting of the "use TSC offsetting" VM-execution control as well as the TSC offset:
    - If the control is 0, the instruction operates normally, loading EAX:EDX with the value of the IA32_TIME_STAMP_COUNTER MSR.
    - If the control is 1, the instruction loads EAX:EDX with the sum (using signed addition) of the value of the IA32_TIME_STAMP_COUNTER MSR and the value of the TSC offset (interpreted as a signed value).

    The 1-setting of the "use TSC-offsetting" VM-execution control does not effect executions of RDMSR if ECX contains 6E0H (indicating the IA32_TSC_DEADLINE MSR). Such executions return the APIC-timer deadline relative to the actual timestamp counter without regard to the TSC offset.
  - If ECX is in the range 800H–8FFH (indicating an APIC MSR), instruction behavior may be modified if the "virtualize x2APIC mode" VM-execution control is 1; see Section 29.5.
- **RDTSC.** Behavior of the RDTSC instruction is determined by the settings of the "RDTSC exiting" and "use TSC offsetting" VM-execution controls as well as the TSC offset:
  - If both controls are 0, RDTSC operates normally.
  - If the "RDTSC exiting" VM-execution control is 0 and the "use TSC offsetting" VM-execution control is 1, RDTSC loads EAX:EDX with the sum (using signed addition) of the value of the IA32_TIME_STAMP_COUNTER MSR and the value of the TSC offset (interpreted as a signed value).
  - If the "RDTSC exiting" VM-execution control is 1, RDTSC causes a VM exit.
- **RDTSCP.** Behavior of the RDTSCP instruction is determined first by the setting of the "enable RDTSCP" VM-execution control:
  - If the "enable RDTSCP" VM-execution control is 0, RDTSCP causes an invalid-opcode exception (#UD).
  - If the "enable RDTSCP" VM-execution control is 1, treatment is based on the settings of the "RDTSC exiting" and "use TSC offsetting" VM-execution controls as well as the TSC offset:
    - If both controls are 0, RDTSCP operates normally.

  - If the "RDTSC exiting" VM-execution control is 0 and the "use TSC offsetting" VM-execution control is 1, RDTSCP loads EAX:EDX with the sum (using signed addition) of the value of the IA32_TIME_STAMP_COUNTER MSR and the value of the TSC offset (interpreted as a signed value); it also loads ECX with the value of bits 31:0 of the IA32_TSC_AUX MSR.
  - If the "RDTSC exiting" VM-execution control is 1, RDTSCP causes a VM exit.
- **SMSW.** The behavior of SMSW is determined by the CR0 guest/host mask and the CR0 read shadow. For each position corresponding to a bit clear in the CR0 guest/host mask, the destination operand is loaded with the value of the corresponding bit in CR0. For each position corresponding to a bit set in the CR0 guest/host mask, the destination operand is loaded with the value of the corresponding bit in the CR0 read shadow. Thus, if every bit is cleared in the CR0 guest/host mask, MOV from CR0 reads normally from CR0; if every bit is set in the CR0 guest/host mask, MOV from CR0 returns the value of the CR0 read shadow.

  Note the following: (1) for any memory destination or for a 16-bit register destination, only the low 16 bits of the CR0 guest/host mask and the CR0 read shadow are used (bits 63:16 of a register destination are left unchanged); (2) for a 32-bit register destination, only the low 32 bits of the CR0 guest/host mask and the CR0 read shadow are used (bits 63:32 of the destination are cleared); and (3) depending on the contents of the CR0 guest/host mask and the CR0 read shadow, bits may be set in the destination that would never be set when reading directly from CR0.
- **WRMSR.** Section 25.1.3 identifies when executions of the WRMSR instruction cause VM exits. If such an execution neither a fault due to CPL > 0 nor a VM exit, the instruction's behavior may be modified for certain values of ECX:
  - If ECX contains 79H (indicating IA32_BIOS_UPDT_TRIG MSR), no microcode update is loaded, and control passes to the next instruction. This implies that microcode updates cannot be loaded in VMX non-root operation.
  - If ECX contains 808H (indicating the TPR MSR), 80BH (the EOI MSR), or 83FH (self-IPI MSR), instruction behavior may modified if the "virtualize x2APIC mode" VM-execution control is 1; see Section 29.5.
- **XRSTORS.** Behavior of the XRSTORS instruction is determined first by the setting of the "enable XSAVES/XRSTORS" VM-execution control:
  - If the "enable XSAVES/XRSTORS" VM-execution control is 0, XRSTORS causes an invalid-opcode exception (#UD).
  - If the "enable XSAVES/XRSTORS" VM-execution control is 1, treatment is based on the value of the XSS-exiting bitmap (see Section 24.6.17):
    - XRSTORS causes a VM exit if any bit is set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap.
    - Otherwise, XRSTORS operates normally.
- **XSAVES.** Behavior of the XSAVES instruction is determined first by the setting of the "enable XSAVES/XRSTORS" VM-execution control:
  - If the "enable XSAVES/XRSTORS" VM-execution control is 0, XSAVES causes an invalid-opcode exception (#UD).
  - If the "enable XSAVES/XRSTORS" VM-execution control is 1, treatment is based on the value of the XSS-exiting bitmap (see Section 24.6.17):
    - XSAVES causes a VM exit if any bit is set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap.
    - Otherwise, XSAVES operates normally.

## 25.4 OTHER CHANGES IN VMX NON-ROOT OPERATION

Treatments of event blocking and of task switches differ in VMX non-root operation as described in the following sections.

### 25.4.1 Event Blocking

Event blocking is modified in VMX non-root operation as follows:

- If the "external-interrupt exiting" VM-execution control is 1, RFLAGS.IF does not control the blocking of external interrupts. In this case, an external interrupt that is not blocked for other reasons causes a VM exit (even if RFLAGS.IF = 0).
- If the "external-interrupt exiting" VM-execution control is 1, external interrupts may or may not be blocked by STI or by MOV SS (behavior is implementation-specific).
- If the "NMI exiting" VM-execution control is 1, non-maskable interrupts (NMIs) may or may not be blocked by STI or by MOV SS (behavior is implementation-specific).

### 25.4.2 Treatment of Task Switches

Task switches are not allowed in VMX non-root operation. Any attempt to effect a task switch in VMX non-root operation causes a VM exit. However, the following checks are performed (in the order indicated), possibly resulting in a fault, before there is any possibility of a VM exit due to task switch:

1. If a task gate is being used, appropriate checks are made on its P bit and on the proper values of the relevant privilege fields. The following cases detail the privilege checks performed:
   a. If CALL, INT *n*, or JMP accesses a task gate in IA-32e mode, a general-protection exception occurs.
   b. If CALL, INT *n*, INT3, INTO, or JMP accesses a task gate outside IA-32e mode, privilege-levels checks are performed on the task gate but, if they pass, privilege levels are not checked on the referenced task-state segment (TSS) descriptor.
   c. If CALL or JMP accesses a TSS descriptor directly in IA-32e mode, a general-protection exception occurs.
   d. If CALL or JMP accesses a TSS descriptor directly outside IA-32e mode, privilege levels are checked on the TSS descriptor.
   e. If a non-maskable interrupt (NMI), an exception, or an external interrupt accesses a task gate in the IDT in IA-32e mode, a general-protection exception occurs.
   f. If a non-maskable interrupt (NMI), an exception other than breakpoint exceptions (#BP) and overflow exceptions (#OF), or an external interrupt accesses a task gate in the IDT outside IA-32e mode, no privilege checks are performed.
   g. If IRET is executed with RFLAGS.NT = 1 in IA-32e mode, a general-protection exception occurs.
   h. If IRET is executed with RFLAGS.NT = 1 outside IA-32e mode, a TSS descriptor is accessed directly and no privilege checks are made.
2. Checks are made on the new TSS selector (for example, that is within GDT limits).
3. The new TSS descriptor is read. (A page fault results if a relevant GDT page is not present).
4. The TSS descriptor is checked for proper values of type (depends on type of task switch), P bit, S bit, and limit.

Only if checks 1–4 all pass (do not generate faults) might a VM exit occur. However, the ordering between a VM exit due to a task switch and a page fault resulting from accessing the old TSS or the new TSS is implementation-specific. Some processors may generate a page fault (instead of a VM exit due to a task switch) if accessing either TSS would cause a page fault. Other processors may generate a VM exit due to a task switch even if accessing either TSS would cause a page fault.

If an attempt at a task switch through a task gate in the IDT causes an exception (before generating a VM exit due to the task switch) and that exception causes a VM exit, information about the event whose delivery that accessed the task gate is recorded in the IDT-vectoring information fields and information about the exception that caused the VM exit is recorded in the VM-exit interruption-information fields. See Section 27.2. The fact that a task gate was being accessed is not recorded in the VMCS.

If an attempt at a task switch through a task gate in the IDT causes VM exit due to the task switch, information about the event whose delivery accessed the task gate is recorded in the IDT-vectoring fields of the VMCS. Since the cause of such a VM exit is a task switch and not an interruption, the valid bit for the VM-exit interruption information field is 0. See Section 27.2.

## 25.5 FEATURES SPECIFIC TO VMX NON-ROOT OPERATION

Some VM-execution controls support features that are specific to VMX non-root operation. These are the VMX-preemption timer (Section 25.5.1) and the monitor trap flag (Section 25.5.2), translation of guest-physical addresses (Section 25.5.3), VM functions (Section 25.5.5), and virtualization exceptions (Section 25.5.6).

### 25.5.1 VMX-Preemption Timer

If the last VM entry was performed with the 1-setting of "activate VMX-preemption timer" VM-execution control, the **VMX-preemption timer** counts down (from the value loaded by VM entry; see Section 26.6.4) in VMX non-root operation. When the timer counts down to zero, it stops counting down and a VM exit occurs (see Section 25.2).

The VMX-preemption timer counts down at rate proportional to that of the timestamp counter (TSC). Specifically, the timer counts down by 1 every time bit X in the TSC changes due to a TSC increment. The value of X is in the range 0–31 and can be determined by consulting the VMX capability MSR IA32_VMX_MISC (see Appendix A.6).

The VMX-preemption timer operates in the C-states C0, C1, and C2; it also operates in the shutdown and wait-for-SIPI states. If the timer counts down to zero in any state other than the wait-for SIPI state, the logical processor transitions to the C0 C-state and causes a VM exit; the timer does not cause a VM exit if it counts down to zero in the wait-for-SIPI state. The timer is not decremented in C-states deeper than C2.

Treatment of the timer in the case of system management interrupts (SMIs) and system-management mode (SMM) depends on whether the treatment of SMIs and SMM:

- If the default treatment of SMIs and SMM (see Section 34.14) is active, the VMX-preemption timer counts across an SMI to VMX non-root operation, subsequent execution in SMM, and the return from SMM via the RSM instruction. However, the timer can cause a VM exit only from VMX non-root operation. If the timer expires during SMI, in SMM, or during RSM, a timer-induced VM exit occurs immediately after RSM with its normal priority unless it is blocked based on activity state (Section 25.2).
- If the dual-monitor treatment of SMIs and SMM (see Section 34.15) is active, transitions into and out of SMM are VM exits and VM entries, respectively. The treatment of the VMX-preemption timer by those transitions is mostly the same as for ordinary VM exits and VM entries; Section 34.15.2 and Section 34.15.4 detail some differences.

### 25.5.2 Monitor Trap Flag

The **monitor trap flag** is a debugging feature that causes VM exits to occur on certain instruction boundaries in VMX non-root operation. Such VM exits are called **MTF VM exits**. An MTF VM exit may occur on an instruction boundary in VMX non-root operation as follows:

- If the "monitor trap flag" VM-execution control is 1 and VM entry is injecting a vectored event (see Section 26.5.1), an MTF VM exit is pending on the instruction boundary before the first instruction following the VM entry.
- If VM entry is injecting a pending MTF VM exit (see Section 26.5.2), an MTF VM exit is pending on the instruction boundary before the first instruction following the VM entry. This is the case even if the "monitor trap flag" VM-execution control is 0.
- If the "monitor trap flag" VM-execution control is 1, VM entry is not injecting an event, and a pending event (e.g., debug exception or interrupt) is delivered before an instruction can execute, an MTF VM exit is pending on the instruction boundary following delivery of the event (or any nested exception).
- Suppose that the "monitor trap flag" VM-execution control is 1, VM entry is not injecting an event, and the first instruction following VM entry is a REP-prefixed string instruction:
  - If the first iteration of the instruction causes a fault, an MTF VM exit is pending on the instruction boundary following delivery of the fault (or any nested exception).
  - If the first iteration of the instruction does not cause a fault, an MTF VM exit is pending on the instruction boundary after that iteration.

- Suppose that the "monitor trap flag" VM-execution control is 1, VM entry is not injecting an event, and the first instruction following VM entry is **not** a REP-prefixed string instruction:
  - If the instruction causes a fault, an MTF VM exit is pending on the instruction boundary following delivery of the fault (or any nested exception).[1]
  - If the instruction does not cause a fault, an MTF VM exit is pending on the instruction boundary following execution of that instruction. If the instruction is INT3 or INTO, this boundary follows delivery of any software exception. If the instruction is INT *n*, this boundary follows delivery of a software interrupt. If the instruction is HLT, the MTF VM exit will be from the HLT activity state.

No MTF VM exit occurs if another VM exit occurs before reaching the instruction boundary on which an MTF VM exit would be pending (e.g., due to an exception or triple fault).

An MTF VM exit occurs on the instruction boundary on which it is pending unless a higher priority event takes precedence or the MTF VM exit is blocked due to the activity state:

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over MTF VM exits. MTF VM exits take priority over debug-trap exceptions and lower priority events.
- No MTF VM exit occurs if the processor is in either the shutdown activity state or wait-for-SIPI activity state. If a non-maskable interrupt subsequently takes the logical processor out of the shutdown activity state without causing a VM exit, an MTF VM exit is pending after delivery of that interrupt.

### 25.5.3 Translation of Guest-Physical Addresses Using EPT

The extended page-table mechanism (EPT) is a feature that can be used to support the virtualization of physical memory. When EPT is in use, certain physical addresses are treated as guest-physical addresses and are not used to access memory directly. Instead, guest-physical addresses are translated by traversing a set of EPT paging structures to produce physical addresses that are used to access memory.

Details of the EPT are given in Section 28.2.

### 25.5.4 APIC Virtualization

APIC virtualization is a collection of features that can be used to support the virtualization of interrupts and the Advanced Programmable Interrupt Controller (APIC). When APIC virtualization is enabled, the processor emulates many accesses to the APIC, tracks the state of the virtual APIC, and delivers virtual interrupts — all in VMX non-root operation without a VM exit.

Details of the APIC virtualization are given in Chapter 29.

### 25.5.5 VM Functions

A **VM function** is an operation provided by the processor that can be invoked from VMX non-root operation without a VM exit. VM functions are enabled and configured by the settings of different fields in the VMCS. Software in VMX non-root operation invokes a VM function with the **VMFUNC** instruction; the value of EAX selects the specific VM function being invoked.

Section 25.5.5.1 explains how VM functions are enabled. Section 25.5.5.2 specifies the behavior of the VMFUNC instruction. Section 25.5.5.3 describes a specific VM function called **EPTP switching**.

#### 25.5.5.1 Enabling VM Functions

Software enables VM functions generally by setting the "enable VM functions" VM-execution control. A specific VM function is enabled by setting the corresponding VM-function control.

1. This item includes the cases of an invalid opcode exception—#UD— generated by the UD2 instruction and a BOUND-range exceeded exception—#BR—generated by the BOUND instruction.

Suppose, for example, that software wants to enable EPTP switching (VM function 0; see Section 24.6.14).To do so, it must set the "activate secondary controls" VM-execution control (bit 31 of the primary processor-based VM-execution controls), the "enable VM functions" VM-execution control (bit 13 of the secondary processor-based VM-execution controls) and the "EPTP switching" VM-function control (bit 0 of the VM-function controls).

### 25.5.5.2 General Operation of the VMFUNC Instruction

The VMFUNC instruction causes an invalid-opcode exception (#UD) if the "enable VM functions" VM-execution controls is 0[1] or the value of EAX is greater than 63 (only VM functions 0–63 can be enable). Otherwise, the instruction causes a VM exit if the bit at position EAX is 0 in the VM-function controls (the selected VM function is not enabled). If such a VM exit occurs, the basic exit reason used is 59 (3BH), indicating "VMFUNC", and the length of the VMFUNC instruction is saved into the VM-exit instruction-length field. If the instruction causes neither an invalid-opcode exception nor a VM exit due to a disabled VM function, it performs the functionality of the VM function specified by the value in EAX.

Individual VM functions may perform additional fault checking (e.g., one might cause a general-protection exception if CPL > 0). In addition, specific VM functions may include checks that might result in a VM exit. If such a VM exit occurs, VM-exit information is saved as described in the previous paragraph. The specification of a VM function may indicate that additional VM-exit information is provided.

The specific behavior of the EPTP-switching VM function (including checks that result in VM exits) is given in Section 25.5.5.3.

### 25.5.5.3 EPTP Switching

EPTP switching is VM function 0. This VM function allows software in VMX non-root operation to load a new value for the EPT pointer (EPTP), thereby establishing a different EPT paging-structure hierarchy (see Section 28.2 for details of the operation of EPT). Software is limited to selecting from a list of potential EPTP values configured in advance by software in VMX root operation.

Specifically, the value of ECX is used to select an entry from the EPTP list, the 4-KByte structure referenced by the EPTP-list address (see Section 24.6.14; because this structure contains 512 8-Byte entries, VMFUNC causes a VM exit if ECX ≥ 512). If the selected entry is a valid EPTP value (it would not cause VM entry to fail; see Section 26.2.1.1), it is stored in the EPTP field of the current VMCS and is used for subsequent accesses using guest-physical addresses. The following pseudocode provides details:

```
IF ECX ≥ 512
    THEN VM exit;
    ELSE
        tent_EPTP ← 8 bytes from EPTP-list address + 8 * ECX;
        IF tent_EPTP is not a valid EPTP value (would cause VM entry to fail if in EPTP)
            THEN VMexit;
            ELSE
                write tent_EPTP to the EPTP field in the current VMCS;
                use tent_EPTP as the new EPTP value for address translation;
                IF processor supports the 1-setting of the "EPT-violation #VE" VM-execution control
                    THEN
                        write ECX[15:0] to EPTP-index field in current VMCS;
                        use ECX[15:0] as EPTP index for subsequent EPT-violation virtualization exceptions (see Section 25.5.6.2);
                FI;
        FI;
FI;
```

Execution of the EPTP-switching VM function does not modify the state of any registers; no flags are modified.

1. "Enable VM functions" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the "enable VM functions" VM-execution control were 0. See Section 24.6.2.

As noted in Section 25.5.5.2, an execution of the EPTP-switching VM function that causes a VM exit (as specified above), uses the basic exit reason 59, indicating "VMFUNC". The length of the VMFUNC instruction is saved into the VM-exit instruction-length field. No additional VM-exit information is provided.

An execution of VMFUNC loads EPTP from the EPTP list (and thus does not cause a fault or VM exit) is called an **EPTP-switching VMFUNC**. After an EPTP-switching VMFUNC, control passes to the next instruction. The logical processor starts creating and using guest-physical and combined mappings associated with the new value of bits 51:12 of EPTP; the combined mappings created and used are associated with the current VPID and PCID (these are not changed by VMFUNC).[1] If the "enable VPID" VM-execution control is 0, an EPTP-switching VMFUNC invalidates combined mappings associated with VPID 0000H (for all PCIDs and for all EP4TA values, where EP4TA is the value of bits 51:12 of EPTP).

Because an EPTP-switching VMFUNC may change the translation of guest-physical addresses, it may affect use of the guest-physical address in CR3. The EPTP-switching VMFUNC cannot itself cause a VM exit due to an EPT violation or an EPT misconfiguration due to the translation of that guest-physical address through the new EPT paging structures. The following items provide details that apply if CR0.PG = 1:

- If 32-bit paging or IA-32e paging is in use (either CR4.PAE = 0 or IA32_EFER.LMA = 1), the next memory access with a linear address uses the translation of the guest-physical address in CR3 through the new EPT paging structures. As a result, this access may cause a VM exit due to an EPT violation or an EPT misconfiguration encountered during that translation.
- If PAE paging is in use (CR4.PAE = 1 and IA32_EFER.LMA = 0), an EPTP-switching VMFUNC **does not** load the four page-directory-pointer-table entries (PDPTEs) from the guest-physical address in CR3. The logical processor continues to use the four guest-physical addresses already present in the PDPTEs. The guest-physical address in CR3 is not translated through the new EPT paging structures (until some operation that would load the PDPTEs).

  The EPTP-switching VMFUNC cannot itself cause a VM exit due to an EPT violation or an EPT misconfiguration encountered during the translation of a guest-physical address in any of the PDPTEs. A subsequent memory access with a linear address uses the translation of the guest-physical address in the appropriate PDPTE through the new EPT paging structures. As a result, such an access may cause a VM exit due to an EPT violation or an EPT misconfiguration encountered during that translation.

If an EPTP-switching VMFUNC establishes an EPTP value that enables accessed and dirty flags for EPT (by setting bit 6), subsequent memory accesses may fail to set those flags as specified if there has been no appropriate execution of INVEPT since the last use of an EPTP value that does not enable accessed and dirty flags for EPT (because bit 6 is clear) and that is identical to the new value on bits 51:12.

IF the processor supports the 1-setting of the "EPT-violation #VE" VM-execution control, an EPTP-switching VMFUNC loads the value in ECX[15:0] into to EPTP-index field in current VMCS. Subsequent EPT-violation virtualization exceptions will save this value into the virtualization-exception information area (see Section 25.5.6.2);

## 25.5.6 Virtualization Exceptions

A **virtualization exception** is a new processor exception. It uses vector 20 and is abbreviated #VE.

A virtualization exception can occur only in VMX non-root operation. Virtualization exceptions occur only with certain settings of certain VM-execution controls. Generally, these settings imply that certain conditions that would normally cause VM exits instead cause virtualization exceptions

In particular, the 1-setting of the "EPT-violation #VE" VM-execution control causes some EPT violations to generate virtualization exceptions instead of VM exits. Section 25.5.6.1 provides the details of how the processor determines whether an EPT violation causes a virtualization exception or a VM exit.

When the processor encounters a virtualization exception, it saves information about the exception to the virtualization-exception information area; see Section 25.5.6.2.

After saving virtualization-exception information, the processor delivers a virtualization exception as it would any other exception; see Section 25.5.6.3 for details.

1. If the "enable VPID" VM-execution control is 0, the current VPID is 0000H; if CR4.PCIDE = 0, the current PCID is 000H.

### 25.5.6.1 Convertible EPT Violations

If the "EPT-violation #VE" VM-execution control is 0 (e.g., on processors that do not support this feature), EPT violations always cause VM exits. If instead the control is 1, certain EPT violations may be converted to cause virtualization exceptions instead; such EPT violations are **convertible**.

The values of certain EPT paging-structure entries determine which EPT violations are convertible. Specifically, bit 63 of certain EPT paging-structure entries may be defined to mean **suppress #VE**:

- If bits 2:0 of an EPT paging-structure entry are all 0, the entry is **not present**. If the processor encounters such an entry while translating a guest-physical address, it causes an EPT violation. The EPT violation is convertible if and only if bit 63 of the entry is 0.
- If bits 2:0 of an EPT paging-structure entry are not all 0, the following cases apply:
  - If the value of the EPT paging-structure entry is not supported, the entry is **misconfigured**. If the processor encounters such an entry while translating a guest-physical address, it causes an EPT misconfiguration (not an EPT violation). EPT misconfigurations always cause VM exits.
  - If the value of the EPT paging-structure entry is supported, the following cases apply:
    - If bit 7 of the entry is 1, or if the entry is an EPT PTE, the entry maps a page. If the processor uses such an entry to translate a guest-physical address, and if an access to that address causes an EPT violation, the EPT violation is convertible if and only if bit 63 of the entry is 0.
    - If bit 7 of the entry is 0 and the entry is not an EPT PTE, the entry references another EPT paging structure. The processor does not use the value of bit 63 of the entry to determine whether any subsequent EPT violation is convertible.

If an access to a guest-physical address causes an EPT violation, bit 63 of exactly one of the EPT paging-structure entries used to translate that address is used to determine whether the EPT violation is convertible: either a entry that is not present (if the guest-physical address does not translate to a physical address) or an entry that maps a page (if it does).

A convertible EPT violation instead causes a virtualization exception if the following all hold:

- CR0.PE = 1;
- the logical processor is not in the process of delivering an event through the IDT; and
- the 32 bits at offset 4 in the virtualization-exception information area are all 0.

Delivery of virtualization exceptions writes the value FFFFFFFFH to offset 4 in the virtualization-exception information area (see Section 25.5.6.2). Thus, once a virtualization exception occurs, another can occur only if software clears this field.

### 25.5.6.2 Virtualization-Exception Information

Virtualization exceptions save data into the virtualization-exception information area (see Section 24.6.16). Table 25-1 enumerates the data saved and the format of the area.

**Table 25-1. Format of the Virtualization-Exception Information Area**

| Byte Offset | Contents |
|---|---|
| 0 | The 32-bit value that would have been saved into the VMCS as an exit reason had a VM exit occurred instead of the virtualization exception. For EPT violations, this value is 48 (00000030H) |
| 4 | FFFFFFFFH |
| 8 | The 64-bit value that would have been saved into the VMCS as an exit qualification had a VM exit occurred instead of the virtualization exception |
| 16 | The 64-bit value that would have been saved into the VMCS as a guest-linear address had a VM exit occurred instead of the virtualization exception |

Table 25-1. Format of the Virtualization-Exception Information Area (Contd.)

| Byte Offset | Contents |
|---|---|
| 24 | The 64-bit value that would have been saved into the VMCS as a guest-physical address had a VM exit occurred instead of the virtualization exception |
| 32 | The current 16-bit value of the EPTP index VM-execution control (see Section 24.6.16 and Section 25.5.5.3) |

### 25.5.6.3 Delivery of Virtualization Exceptions

After saving virtualization-exception information, the processor treats a virtualization exception as it does other exceptions:

- If bit 20 (#VE) is 1 in the exception bitmap in the VMCS, a virtualization exception causes a VM exit (see below). If the bit is 0, the virtualization exception is delivered using gate descriptor 20 in the IDT.
- Virtualization exceptions produce no error code. Delivery of a virtualization exception pushes no error code on the stack.
- With respect to double faults, virtualization exceptions have the same severity as page faults. If delivery of a virtualization exception encounters a nested fault that is either contributory or a page fault, a double fault (#DF) is generated. See Chapter 6, "Interrupt 8—Double Fault Exception (#DF)" in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

  It is not possible for a virtualization exception to be encountered while delivering another exception (see Section 25.5.6.1).

If a virtualization exception causes a VM exit directly (because bit 20 is 1 in the exception bitmap), information about the exception is saved normally in the VM-exit interruption information field in the VMCS (see Section 27.2.2). Specifically, the event is reported as a hardware exception with vector 20 and no error code. Bit 12 of the field (NMI unblocking due to IRET) is set normally.

If a virtualization exception causes a VM exit indirectly (because bit 20 is 0 in the exception bitmap and delivery of the exception generates an event that causes a VM exit), information about the exception is saved normally in the IDT-vectoring information field in the VMCS (see Section 27.2.3). Specifically, the event is reported as a hardware exception with vector 20 and no error code.

## 25.6 UNRESTRICTED GUESTS

The first processors to support VMX operation require CR0.PE and CR0.PG to be 1 in VMX operation (see Section 23.8). This restriction implies that guest software cannot be run in unpaged protected mode or in real-address mode. Later processors support a VM-execution control called "unrestricted guest".[1] If this control is 1, CR0.PE and CR0.PG may be 0 in VMX non-root operation. Such processors allow guest software to run in unpaged protected mode or in real-address mode. The following items describe the behavior of such software:

- The MOV CR0 instructions does not cause a general-protection exception simply because it would set either CR0.PE and CR0.PG to 0. See Section 25.3 for details.
- A logical processor treats the values of CR0.PE and CR0.PG in VMX non-root operation just as it does outside VMX operation. Thus, if CR0.PE = 0, the processor operates as it does normally in real-address mode (for example, it uses the 16-bit **interrupt table** to deliver interrupts and exceptions). If CR0.PG = 0, the processor operates as it does normally when paging is disabled.
- Processor operation is modified by the fact that the processor is in VMX non-root operation and by the settings of the VM-execution controls just as it is in protected mode or when paging is enabled. Instructions, interrupts, and exceptions that cause VM exits in protected mode or when paging is enabled also do so in real-address mode or when paging is disabled. The following examples should be noted:

1. "Unrestricted guest" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the "unrestricted guest" VM-execution control were 0. See Section 24.6.2.

  - If CR0.PG = 0, page faults do not occur and thus cannot cause VM exits.
  - If CR0.PE = 0, invalid-TSS exceptions do not occur and thus cannot cause VM exits.
  - If CR0.PE = 0, the following instructions cause invalid-opcode exceptions and do not cause VM exits: INVEPT, INVVPID, LLDT, LTR, SLDT, STR, VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMREAD, VMRESUME, VMWRITE, VMXOFF, and VMXON.
- If CR0.PG = 0, each linear address is passed directly to the EPT mechanism for translation to a physical address.[1] The guest memory type passed on to the EPT mechanism is WB (writeback).

1. As noted in Section 26.2.1.1, the "enable EPT" VM-execution control must be 1 if the "unrestricted guest" VM-execution control is 1.

# CHAPTER 26
# VM ENTRIES

Software can enter VMX non-root operation using either of the VM-entry instructions VMLAUNCH and VMRESUME. VMLAUNCH can be used only with a VMCS whose launch state is clear and VMRESUME can be used only with a VMCS whose the launch state is launched. VMLAUNCH should be used for the first VM entry after VMCLEAR; VMRESUME should be used for subsequent VM entries with the same VMCS.

Each VM entry performs the following steps in the order indicated:

1. Basic checks are performed to ensure that VM entry can commence (Section 26.1).
2. The control and host-state areas of the VMCS are checked to ensure that they are proper for supporting VMX non-root operation and that the VMCS is correctly configured to support the next VM exit (Section 26.2).
3. The following may be performed in parallel or in any order (Section 26.3):
   - The guest-state area of the VMCS is checked to ensure that, after the VM entry completes, the state of the logical processor is consistent with IA-32 and Intel 64 architectures.
   - Processor state is loaded from the guest-state area and based on controls in the VMCS.
   - Address-range monitoring is cleared.
4. MSRs are loaded from the VM-entry MSR-load area (Section 26.4).
5. If VMLAUNCH is being executed, the launch state of the VMCS is set to "launched."
6. An event may be injected in the guest context (Section 26.5).

Steps 1–4 above perform checks that may cause VM entry to fail. Such failures occur in one of the following three ways:

- Some of the checks in Section 26.1 may generate ordinary faults (for example, an invalid-opcode exception). Such faults are delivered normally.
- Some of the checks in Section 26.1 and all the checks in Section 26.2 cause control to pass to the instruction following the VM-entry instruction. The failure is indicated by setting RFLAGS.ZF[1] (if there is a current VMCS) or RFLAGS.CF (if there is no current VMCS). If there is a current VMCS, an error number indicating the cause of the failure is stored in the VM-instruction error field. See Chapter 30 for the error numbers.
- The checks in Section 26.3 and Section 26.4 cause processor state to be loaded from the host-state area of the VMCS (as would be done on a VM exit). Information about the failure is stored in the VM-exit information fields. See Section 26.7 for details.

EFLAGS.TF = 1 causes a VM-entry instruction to generate a single-step debug exception only if failure of one of the checks in Section 26.1 and Section 26.2 causes control to pass to the following instruction. A VM-entry does not generate a single-step debug exception in any of the following cases: (1) the instruction generates a fault; (2) failure of one of the checks in Section 26.3 or in loading MSRs causes processor state to be loaded from the host-state area of the VMCS; or (3) the instruction passes all checks in Section 26.1, Section 26.2, and Section 26.3 and there is no failure in loading MSRs.

Section 34.15 describes the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM). Under this treatment, code running in SMM returns using VM entries instead of the RSM instruction. A VM entry **returns from SMM** if it is executed in SMM and the "entry to SMM" VM-entry control is 0. VM entries that return from SMM differ from ordinary VM entries in ways that are detailed in Section 34.15.4.

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For IA-32 processors, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.

# 26.1 BASIC VM-ENTRY CHECKS

Before a VM entry commences, the current state of the logical processor is checked in the following order:

1. If the logical processor is in virtual-8086 mode or compatibility mode, an invalid-opcode exception is generated.
2. If the current privilege level (CPL) is not zero, a general-protection exception is generated.
3. If there is no current VMCS, RFLAGS.CF is set to 1 and control passes to the next instruction.
4. If there is a current VMCS but the current VMCS is a shadow VMCS (see Section 24.10), RFLAGS.CF is set to 1 and control passes to the next instruction.
5. If there is a current VMCS that is not a shadow VMCS, the following conditions are evaluated in order; any of these cause VM entry to fail:
   a. if there is MOV-SS blocking (see Table 24-3)
   b. if the VM entry is invoked by VMLAUNCH and the VMCS launch state is not clear
   c. if the VM entry is invoked by VMRESUME and the VMCS launch state is not launched

   If any of these checks fail, RFLAGS.ZF is set to 1 and control passes to the next instruction. An error number indicating the cause of the failure is stored in the VM-instruction error field. See Chapter 30 for the error numbers.

# 26.2 CHECKS ON VMX CONTROLS AND HOST-STATE AREA

If the checks in Section 26.1 do not cause VM entry to fail, the control and host-state areas of the VMCS are checked to ensure that they are proper for supporting VMX non-root operation, that the VMCS is correctly configured to support the next VM exit, and that, after the next VM exit, the processor's state is consistent with the Intel 64 and IA-32 architectures.

VM entry fails if any of these checks fail. When such failures occur, control is passed to the next instruction, RFLAGS.ZF is set to 1 to indicate the failure, and the VM-instruction error field is loaded with an error number that indicates whether the failure was due to the controls or the host-state area (see Chapter 30).

These checks may be performed in any order. Thus, an indication by error number of one cause (for example, host state) does not imply that there are not also other errors. Different processors may thus give different error numbers for the same VMCS. Some checks prevent establishment of settings (or combinations of settings) that are currently reserved. Future processors may allow such settings (or combinations) and may not perform the corresponding checks. The correctness of software should not rely on VM-entry failures resulting from the checks documented in this section.

The checks on the controls and the host-state area are presented in Section 26.2.1 through Section 26.2.4. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the host-state area.

## 26.2.1 Checks on VMX Controls

This section identifies VM-entry checks on the VMX control fields.

### 26.2.1.1 VM-Execution Control Fields

VM entries perform the following checks on the VM-execution control fields:[1]

- Reserved bits in the pin-based VM-execution controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix A.3.1).

1. If the "activate secondary controls" primary processor-based VM-execution control is 0, VM entry operates as if each secondary processor-based VM-execution control were 0.

- Reserved bits in the primary processor-based VM-execution controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix A.3.2).
- If the "activate secondary controls" primary processor-based VM-execution control is 1, reserved bits in the secondary processor-based VM-execution controls must be cleared. Software may consult the VMX capability MSRs to determine which bits are reserved (see Appendix A.3.3).

  If the "activate secondary controls" primary processor-based VM-execution control is 0 (or if the processor does not support the 1-setting of that control), no checks are performed on the secondary processor-based VM-execution controls. The logical processor operates as if all the secondary processor-based VM-execution controls were 0.
- The CR3-target count must not be greater than 4. Future processors may support a different number of CR3-target values. Software should read the VMX capability MSR IA32_VMX_MISC to determine the number of values supported (see Appendix A.6).
- If the "use I/O bitmaps" VM-execution control is 1, bits 11:0 of each I/O-bitmap address must be 0. Neither address should set any bits beyond the processor's physical-address width.[1,2]
- If the "use MSR bitmaps" VM-execution control is 1, bits 11:0 of the MSR-bitmap address must be 0. The address should not set any bits beyond the processor's physical-address width.[3]
- If the "use TPR shadow" VM-execution control is 1, the virtual-APIC address must satisfy the following checks:
  - Bits 11:0 of the address must be 0.
  - The address should not set any bits beyond the processor's physical-address width.[4]

  If all of the above checks are satisfied and the "use TPR shadow" VM-execution control is 1, bytes 3:1 of VTPR (see Section 29.1.1) may be cleared (behavior may be implementation-specific).

  The clearing of these bytes may occur even if the VM entry fails. This is true either if the failure causes control to pass to the instruction following the VM-entry instruction or if it causes processor state to be loaded from the host-state area of the VMCS.
- If the "use TPR shadow" VM-execution control is 1 and the "virtual-interrupt delivery" VM-execution control is 0, bits 31:4 of the TPR threshold VM-execution control field must be 0.[5]
- The following check is performed if the "use TPR shadow" VM-execution control is 1 and the "virtualize APIC accesses" and "virtual-interrupt delivery" VM-execution controls are both 0: the value of bits 3:0 of the TPR threshold VM-execution control field should not be greater than the value of bits 7:4 of VTPR (see Section 29.1.1).
- If the "NMI exiting" VM-execution control is 0, the "virtual NMIs" VM-execution control must be 0.
- If the "virtual NMIs" VM-execution control is 0, the "NMI-window exiting" VM-execution control must be 0.
- If the "virtualize APIC-accesses" VM-execution control is 1, the APIC-access address must satisfy the following checks:
  - Bits 11:0 of the address must be 0.
  - The address should not set any bits beyond the processor's physical-address width.[6]
- If the "use TPR shadow" VM-execution control is 0, the following VM-execution controls must also be 0: "virtualize x2APIC mode", "APIC-register virtualization", and "virtual-interrupt delivery".[7]

---

1. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
2. If IA32_VMX_BASIC[48] is read as 1, these addresses must not set any bits in the range 63:32; see Appendix A.1.
3. If IA32_VMX_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix A.1.
4. If IA32_VMX_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix A.1.
5. "Virtual-interrupt delivery" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "virtual-interrupt delivery" VM-execution control were 0. See Section 24.6.2.
6. If IA32_VMX_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix A.1.
7. "Virtualize x2APIC mode" and "APIC-register virtualization" are secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if these controls were 0. See Section 24.6.2.

- If the "virtualize x2APIC mode" VM-execution control is 1, the "virtualize APIC accesses" VM-execution control must be 0.
- If the "virtual-interrupt delivery" VM-execution control is 1, the "external-interrupt exiting" VM-execution control must be 1.
- If the "process posted interrupts" VM-execution control is 1, the following must be true:[1]
  - The "virtual-interrupt delivery" VM-execution control is 1.
  - The "acknowledge interrupt on exit" VM-exit control is 1.
  - The posted-interrupt notification vector has a value in the range 0–255 (bits 15:8 are all 0).
  - Bits 5:0 of the posted-interrupt descriptor address are all 0.
  - The posted-interrupt descriptor address does not set any bits beyond the processor's physical-address width.[2]
- If the "enable VPID" VM-execution control is 1, the value of the VPID VM-execution control field must not be 0000H.[3]
- If the "enable EPT" VM-execution control is 1, the EPTP VM-execution control field (see Table 24-8 in Section 24.6.11) must satisfy the following checks:[4]
  - The EPT memory type (bits 2:0) must be a value supported by the processor as indicated in the IA32_VMX_EPT_VPID_CAP MSR (see Appendix A.10).
  - Bits 5:3 (1 less than the EPT page-walk length) must be 3, indicating an EPT page-walk length of 4; see Section 28.2.2.
  - Bit 6 (enable bit for accessed and dirty flags for EPT) must be 0 if bit 21 of the IA32_VMX_EPT_VPID_CAP MSR (see Appendix A.10) is read as 0, indicating that the processor does not support accessed and dirty flags for EPT.
  - Reserved bits 11:7 and 63:N (where N is the processor's physical-address width) must all be 0.
  - If the "unrestricted guest" VM-execution control is 1, the "enable EPT" VM-execution control must also be 1.[5]
- If the "enable VM functions" processor-based VM-execution control is 1, reserved bits in the VM-function controls must be clear.[6] Software may consult the VMX capability MSRs to determine which bits are reserved (see Appendix A.11). In addition, the following check is performed based on the setting of bits in the VM-function controls (see Section 24.6.14):
  - If "EPTP switching" VM-function control is 1, the "enable EPT" VM-execution control must also 1. In addition, the EPTP-list address must satisfy the following checks:
    - Bits 11:0 of the address must be 0.
    - The address must not set any bits beyond the processor's physical-address width.

  If the "enable VM functions" processor-based VM-execution control is 0, no checks are performed on the VM-function controls.
- If the "VMCS shadowing" VM-execution control is 1, the VMREAD-bitmap and VMWRITE-bitmap addresses must each satisfy the following checks:[7]

1. "Process posted interrupts" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "process posted interrupts" VM-execution control were 0. See Section 24.6.2.
2. If IA32_VMX_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix A.1.
3. "Enable VPID" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "enable VPID" VM-execution control were 0. See Section 24.6.2.
4. "Enable EPT" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "enable EPT" VM-execution control were 0. See Section 24.6.2.
5. "Unrestricted guest" and "enable EPT" are both secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if both these controls were 0. See Section 24.6.2.
6. "Enable VM functions" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "enable VM functions" VM-execution control were 0. See Section 24.6.2.

— Bits 11:0 of the address must be 0.

— The address must not set any bits beyond the processor's physical-address width.

- If the "EPT-violation #VE" VM-execution control is 1, the virtualization-exception information address must satisfy the following checks:[1]

  — Bits 11:0 of the address must be 0.

  — The address must not set any bits beyond the processor's physical-address width.

#### 26.2.1.2 VM-Exit Control Fields

VM entries perform the following checks on the VM-exit control fields.

- Reserved bits in the VM-exit controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix A.4).
- If "activate VMX-preemption timer" VM-execution control is 0, the "save VMX-preemption timer value" VM-exit control must also be 0.
- The following checks are performed for the VM-exit MSR-store address if the VM-exit MSR-store count field is non-zero:

  — The lower 4 bits of the VM-exit MSR-store address must be 0. The address should not set any bits beyond the processor's physical-address width.[2]

  — The address of the last byte in the VM-exit MSR-store area should not set any bits beyond the processor's physical-address width. The address of this last byte is VM-exit MSR-store address + (MSR count * 16) – 1. (The arithmetic used for the computation uses more bits than the processor's physical-address width.)

  If IA32_VMX_BASIC[48] is read as 1, neither address should set any bits in the range 63:32; see Appendix A.1.
- The following checks are performed for the VM-exit MSR-load address if the VM-exit MSR-load count field is non-zero:

  — The lower 4 bits of the VM-exit MSR-load address must be 0. The address should not set any bits beyond the processor's physical-address width.

  — The address of the last byte in the VM-exit MSR-load area should not set any bits beyond the processor's physical-address width. The address of this last byte is VM-exit MSR-load address + (MSR count * 16) – 1. (The arithmetic used for the computation uses more bits than the processor's physical-address width.)

  If IA32_VMX_BASIC[48] is read as 1, neither address should set any bits in the range 63:32; see Appendix A.1.

#### 26.2.1.3 VM-Entry Control Fields

VM entries perform the following checks on the VM-entry control fields.

- Reserved bits in the VM-entry controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix A.5).
- Fields relevant to VM-entry event injection must be set properly. These fields are the VM-entry interruption-information field (see Table 24-13 in Section 24.8.3), the VM-entry exception error code, and the VM-entry

---

7. "VMCS shadowing" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "VMCS shadowing" VM-execution control were 0. See Section 24.6.2.

1. "EPT-violation #VE" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "EPT-violation #VE" VM-execution control were 0. See Section 24.6.2.

2. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

instruction length. If the valid bit (bit 31) in the VM-entry interruption-information field is 1, the following must hold:

— The field's interruption type (bits 10:8) is not set to a reserved value. Value 1 is reserved on all logical processors; value 7 (other event) is reserved on logical processors that do not support the 1-setting of the "monitor trap flag" VM-execution control.

— The field's vector (bits 7:0) is consistent with the interruption type:

- If the interruption type is non-maskable interrupt (NMI), the vector is 2.
- If the interruption type is hardware exception, the vector is at most 31.
- If the interruption type is other event, the vector is 0 (pending MTF VM exit).

— The field's deliver-error-code bit (bit 11) is 1 if and only if (1) either (a) the "unrestricted guest" VM-execution control is 0; or (b) bit 0 (corresponding to CR0.PE) is set in the CR0 field in the guest-state area; (2) the interruption type is hardware exception; and (3) the vector indicates an exception that would normally deliver an error code (8 = #DF; 10 = TS; 11 = #NP; 12 = #SS; 13 = #GP; 14 = #PF; or 17 = #AC).

— Reserved bits in the field (30:12) are 0.

— If the deliver-error-code bit (bit 11) is 1, bits 31:15 of the VM-entry exception error-code field are 0.

— If the interruption type is software interrupt, software exception, or privileged software exception, the VM-entry instruction-length field is in the range 1–15.

- The following checks are performed for the VM-entry MSR-load address if the VM-entry MSR-load count field is non-zero:

  — The lower 4 bits of the VM-entry MSR-load address must be 0. The address should not set any bits beyond the processor's physical-address width.[1]

  — The address of the last byte in the VM-entry MSR-load area should not set any bits beyond the processor's physical-address width. The address of this last byte is VM-entry MSR-load address + (MSR count * 16) – 1. (The arithmetic used for the computation uses more bits than the processor's physical-address width.)

  If IA32_VMX_BASIC[48] is read as 1, neither address should set any bits in the range 63:32; see Appendix A.1.

- If the processor is not in SMM, the "entry to SMM" and "deactivate dual-monitor treatment" VM-entry controls must be 0.
- The "entry to SMM" and "deactivate dual-monitor treatment" VM-entry controls cannot both be 1.

### 26.2.2 Checks on Host Control Registers and MSRs

The following checks are performed on fields in the host-state area that correspond to control registers and MSRs:

- The CR0 field must not set any bit to a value not supported in VMX operation (see Section 23.8).[2]
- The CR4 field must not set any bit to a value not supported in VMX operation (see Section 23.8).
- On processors that support Intel 64 architecture, the CR3 field must be such that bits 63:52 and bits in the range 51:32 beyond the processor's physical-address width must be 0.[3,4]
- On processors that support Intel 64 architecture, the IA32_SYSENTER_ESP field and the IA32_SYSENTER_EIP field must each contain a canonical address.

1. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
2. The bits corresponding to CR0.NW (bit 29) and CR0.CD (bit 30) are never checked because the values of these bits are not changed by VM exit; see Section 27.5.1.
3. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
4. Bit 63 of the CR3 field in the host-state area must be 0. This is true even though, If CR4.PCIDE = 1, bit 63 of the source operand to MOV to CR3 is used to determine whether cached translation information is invalidated.

- If the "load IA32_PERF_GLOBAL_CTRL" VM-exit control is 1, bits reserved in the IA32_PERF_GLOBAL_CTRL MSR must be 0 in the field for that register (see Figure 18-3).
- If the "load IA32_PAT" VM-exit control is 1, the value of the field for the IA32_PAT MSR must be one that could be written by WRMSR without fault at CPL 0. Specifically, each of the 8 bytes in the field must have one of the values 0 (UC), 1 (WC), 4 (WT), 5 (WP), 6 (WB), or 7 (UC-).
- If the "load IA32_EFER" VM-exit control is 1, bits reserved in the IA32_EFER MSR must be 0 in the field for that register. In addition, the values of the LMA and LME bits in the field must each be that of the "host address-space size" VM-exit control.

### 26.2.3 Checks on Host Segment and Descriptor-Table Registers

The following checks are performed on fields in the host-state area that correspond to segment and descriptor-table registers:

- In the selector field for each of CS, SS, DS, ES, FS, GS and TR, the RPL (bits 1:0) and the TI flag (bit 2) must be 0.
- The selector fields for CS and TR cannot be 0000H.
- The selector field for SS cannot be 0000H if the "host address-space size" VM-exit control is 0.
- On processors that support Intel 64 architecture, the base-address fields for FS, GS, GDTR, IDTR, and TR must contain canonical addresses.

### 26.2.4 Checks Related to Address-Space Size

On processors that support Intel 64 architecture, the following checks related to address-space size are performed on VMX controls and fields in the host-state area:

- If the logical processor is outside IA-32e mode (if IA32_EFER.LMA = 0) at the time of VM entry, the following must hold:
  - The "IA-32e mode guest" VM-entry control is 0.
  - The "host address-space size" VM-exit control is 0.
- If the logical processor is in IA-32e mode (if IA32_EFER.LMA = 1) at the time of VM entry, the "host address-space size" VM-exit control must be 1.
- If the "host address-space size" VM-exit control is 0, the following must hold:
  - The "IA-32e mode guest" VM-entry control is 0.
  - Bit 17 of the CR4 field (corresponding to CR4.PCIDE) is 0.
  - Bits 63:32 in the RIP field is 0.
- If the "host address-space size" VM-exit control is 1, the following must hold:
  - Bit 5 of the CR4 field (corresponding to CR4.PAE) is 1.
  - The RIP field contains a canonical address.

On processors that do not support Intel 64 architecture, checks are performed to ensure that the "IA-32e mode guest" VM-entry control and the "host address-space size" VM-exit control are both 0.

## 26.3 CHECKING AND LOADING GUEST STATE

If all checks on the VMX controls and the host-state area pass (see Section 26.2), the following operations take place concurrently: (1) the guest-state area of the VMCS is checked to ensure that, after the VM entry completes, the state of the logical processor is consistent with IA-32 and Intel 64 architectures; (2) processor state is loaded from the guest-state area or as specified by the VM-entry control fields; and (3) address-range monitoring is cleared.

Because the checking and the loading occur concurrently, a failure may be discovered only after some state has been loaded. For this reason, the logical processor responds to such failures by loading state from the host-state area, as it would for a VM exit. See Section 26.7.

## 26.3.1 Checks on the Guest State Area

This section describes checks performed on fields in the guest-state area. These checks may be performed in any order. Some checks prevent establishment of settings (or combinations of settings) that are currently reserved. Future processors may allow such settings (or combinations) and may not perform the corresponding checks. The correctness of software should not rely on VM-entry failures resulting from the checks documented in this section.

The following subsections reference fields that correspond to processor state. Unless otherwise stated, these references are to fields in the guest-state area.

### 26.3.1.1 Checks on Guest Control Registers, Debug Registers, and MSRs

The following checks are performed on fields in the guest-state area corresponding to control registers, debug registers, and MSRs:

- The CR0 field must not set any bit to a value not supported in VMX operation (see Section 23.8). The following are exceptions:
  - Bit 0 (corresponding to CR0.PE) and bit 31 (PG) are not checked if the "unrestricted guest" VM-execution control is 1.[1]
  - Bit 29 (corresponding to CR0.NW) and bit 30 (CD) are never checked because the values of these bits are not changed by VM entry; see Section 26.3.2.1.
- If bit 31 in the CR0 field (corresponding to PG) is 1, bit 0 in that field (PE) must also be 1.[2]
- The CR4 field must not set any bit to a value not supported in VMX operation (see Section 23.8).
- If the "load debug controls" VM-entry control is 1, bits reserved in the IA32_DEBUGCTL MSR must be 0 in the field for that register. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus performed this check unconditionally.
- The following checks are performed on processors that support Intel 64 architecture:
  - If the "IA-32e mode guest" VM-entry control is 1, bit 31 in the CR0 field (corresponding to CR0.PG) and bit 5 in the CR4 field (corresponding to CR4.PAE) must each be 1.[3]
  - If the "IA-32e mode guest" VM-entry control is 0, bit 17 in the CR4 field (corresponding to CR4.PCIDE) must each be 0.
  - The CR3 field must be such that bits 63:52 and bits in the range 51:32 beyond the processor's physical-address width are 0.[4,5]
  - If the "load debug controls" VM-entry control is 1, bits 63:32 in the DR7 field must be 0. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus performed this check unconditionally (if they supported Intel 64 architecture).
  - The IA32_SYSENTER_ESP field and the IA32_SYSENTER_EIP field must each contain a canonical address.

1. "Unrestricted guest" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "unrestricted guest" VM-execution control were 0. See Section 24.6.2.
2. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PE must be 1 in VMX operation, bit 0 in the CR0 field must be 1 unless the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
3. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PG must be 1 in VMX operation, bit 31 in the CR0 field must be 1 unless the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
4. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
5. Bit 63 of the CR3 field in the guest-state area must be 0. This is true even though, If CR4.PCIDE = 1, bit 63 of the source operand to MOV to CR3 is used to determine whether cached translation information is invalidated.

- If the "load IA32_PERF_GLOBAL_CTRL" VM-entry control is 1, bits reserved in the IA32_PERF_GLOBAL_CTRL MSR must be 0 in the field for that register (see Figure 18-3).
- If the "load IA32_PAT" VM-entry control is 1, the value of the field for the IA32_PAT MSR must be one that could be written by WRMSR without fault at CPL 0. Specifically, each of the 8 bytes in the field must have one of the values 0 (UC), 1 (WC), 4 (WT), 5 (WP), 6 (WB), or 7 (UC-).
- If the "load IA32_EFER" VM-entry control is 1, the following checks are performed on the field for the IA32_EFER MSR :
  - Bits reserved in the IA32_EFER MSR must be 0.
  - Bit 10 (corresponding to IA32_EFER.LMA) must equal the value of the "IA-32e mode guest" VM-exit control. It must also be identical to bit 8 (LME) if bit 31 in the CR0 field (corresponding to CR0.PG) is 1.[1]

### 26.3.1.2 Checks on Guest Segment Registers

This section specifies the checks on the fields for CS, SS, DS, ES, FS, GS, TR, and LDTR. The following terms are used in defining these checks:

- The guest will be **virtual-8086** if the VM flag (bit 17) is 1 in the RFLAGS field in the guest-state area.
- The guest will be **IA-32e mode** if the "IA-32e mode guest" VM-entry control is 1. (This is possible only on processors that support Intel 64 architecture.)
- Any one of these registers is said to be **usable** if the unusable bit (bit 16) is 0 in the access-rights field for that register.

The following are the checks on these fields:

- Selector fields.
  - TR. The TI flag (bit 2) must be 0.
  - LDTR. If LDTR is usable, the TI flag (bit 2) must be 0.
  - SS. If the guest will not be virtual-8086 and the "unrestricted guest" VM-execution control is 0, the RPL (bits 1:0) must equal the RPL of the selector field for CS.[2]
- Base-address fields.
  - CS, SS, DS, ES, FS, GS. If the guest will be virtual-8086, the address must be the selector field shifted left 4 bits (multiplied by 16).
  - The following checks are performed on processors that support Intel 64 architecture:
    - TR, FS, GS. The address must be canonical.
    - LDTR. If LDTR is usable, the address must be canonical.
    - CS. Bits 63:32 of the address must be zero.
    - SS, DS, ES. If the register is usable, bits 63:32 of the address must be zero.
- Limit fields for CS, SS, DS, ES, FS, GS. If the guest will be virtual-8086, the field must be 0000FFFFH.
- Access-rights fields.
  - CS, SS, DS, ES, FS, GS.
    - If the guest will be virtual-8086, the field must be 000000F3H. This implies the following:
      - Bits 3:0 (Type) must be 3, indicating an expand-up read/write accessed data segment.
      - Bit 4 (S) must be 1.
      - Bits 6:5 (DPL) must be 3.

1. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PG must be 1 in VMX operation, bit 31 in the CR0 field must be 1 unless the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
2. "Unrestricted guest" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "unrestricted guest" VM-execution control were 0. See Section 24.6.2.

— Bit 7 (P) must be 1.

— Bits 11:8 (reserved), bit 12 (software available), bit 13 (reserved/L), bit 14 (D/B), bit 15 (G), bit 16 (unusable), and bits 31:17 (reserved) must all be 0.

- If the guest will not be virtual-8086, the different sub-fields are considered separately:

— Bits 3:0 (Type).

- CS. The values allowed depend on the setting of the "unrestricted guest" VM-execution control:

— If the control is 0, the Type must be 9, 11, 13, or 15 (accessed code segment).

— If the control is 1, the Type must be either 3 (read/write accessed expand-up data segment) or one of 9, 11, 13, and 15 (accessed code segment).

- SS. If SS is usable, the Type must be 3 or 7 (read/write, accessed data segment).
- DS, ES, FS, GS. The following checks apply if the register is usable:

— Bit 0 of the Type must be 1 (accessed).

— If bit 3 of the Type is 1 (code segment), then bit 1 of the Type must be 1 (readable).

— Bit 4 (S). If the register is CS or if the register is usable, S must be 1.

— Bits 6:5 (DPL).

- CS.

— If the Type is 3 (read/write accessed expand-up data segment), the DPL must be 0. The Type can be 3 only if the "unrestricted guest" VM-execution control is 1.

— If the Type is 9 or 11 (non-conforming code segment), the DPL must equal the DPL in the access-rights field for SS.

— If the Type is 13 or 15 (conforming code segment), the DPL cannot be greater than the DPL in the access-rights field for SS.

- SS.

— If the "unrestricted guest" VM-execution control is 0, the DPL must equal the RPL from the selector field.

— The DPL must be 0 either if the Type in the access-rights field for CS is 3 (read/write accessed expand-up data segment) or if bit 0 in the CR0 field (corresponding to CR0.PE) is 0.[1]

- DS, ES, FS, GS. The DPL cannot be less than the RPL in the selector field if (1) the "unrestricted guest" VM-execution control is 0; (2) the register is usable; and (3) the Type in the access-rights field is in the range 0 – 11 (data segment or non-conforming code segment).

— Bit 7 (P). If the register is CS or if the register is usable, P must be 1.

— Bits 11:8 (reserved). If the register is CS or if the register is usable, these bits must all be 0.

— Bit 14 (D/B). For CS, D/B must be 0 if the guest will be IA-32e mode and the L bit (bit 13) in the access-rights field is 1.

— Bit 15 (G). The following checks apply if the register is CS or if the register is usable:

- If any bit in the limit field in the range 11:0 is 0, G must be 0.
- If any bit in the limit field in the range 31:20 is 1, G must be 1.

— Bits 31:17 (reserved). If the register is CS or if the register is usable, these bits must all be 0.

— TR. The different sub-fields are considered separately:

1. The following apply if either the "unrestricted guest" VM-execution control or bit 31 of the primary processor-based VM-execution controls is 0: (1) bit 0 in the CR0 field must be 1 if the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PE must be 1 in VMX operation; and (2) the Type in the access-rights field for CS cannot be 3.

- Bits 3:0 (Type).
  - If the guest will not be IA-32e mode, the Type must be 3 (16-bit busy TSS) or 11 (32-bit busy TSS).
  - If the guest will be IA-32e mode, the Type must be 11 (64-bit busy TSS).
- Bit 4 (S). S must be 0.
- Bit 7 (P). P must be 1.
- Bits 11:8 (reserved). These bits must all be 0.
- Bit 15 (G).
  - If any bit in the limit field in the range 11:0 is 0, G must be 0.
  - If any bit in the limit field in the range 31:20 is 1, G must be 1.
- Bit 16 (Unusable). The unusable bit must be 0.
- Bits 31:17 (reserved). These bits must all be 0.

— LDTR. The following checks on the different sub-fields apply only if LDTR is usable:

- Bits 3:0 (Type). The Type must be 2 (LDT).
- Bit 4 (S). S must be 0.
- Bit 7 (P). P must be 1.
- Bits 11:8 (reserved). These bits must all be 0.
- Bit 15 (G).
  - If any bit in the limit field in the range 11:0 is 0, G must be 0.
  - If any bit in the limit field in the range 31:20 is 1, G must be 1.
- Bits 31:17 (reserved). These bits must all be 0.

### 26.3.1.3 Checks on Guest Descriptor-Table Registers

The following checks are performed on the fields for GDTR and IDTR:

- On processors that support Intel 64 architecture, the base-address fields must contain canonical addresses.
- Bits 31:16 of each limit field must be 0.

### 26.3.1.4 Checks on Guest RIP and RFLAGS

The following checks are performed on fields in the guest-state area corresponding to RIP and RFLAGS:

- RIP. The following checks are performed on processors that support Intel 64 architecture:
  - Bits 63:32 must be 0 if the "IA-32e mode guest" VM-entry control is 0 or if the L bit (bit 13) in the access-rights field for CS is 0.
  - If the processor supports N < 64 linear-address bits, bits 63:N must be identical if the "IA-32e mode guest" VM-entry control is 1 and the L bit in the access-rights field for CS is 1.[1] (No check applies if the processor supports 64 linear-address bits.)
- RFLAGS.
  - Reserved bits 63:22 (bits 31:22 on processors that do not support Intel 64 architecture), bit 15, bit 5 and bit 3 must be 0 in the field, and reserved bit 1 must be 1.
  - The VM flag (bit 17) must be 0 either if the "IA-32e mode guest" VM-entry control is 1 or if bit 0 in the CR0 field (corresponding to CR0.PE) is 0.[2]

1. Software can determine the number N by executing CPUID with 80000008H in EAX. The number of linear-address bits supported is returned in bits 15:8 of EAX.

— The IF flag (RFLAGS[bit 9]) must be 1 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) is external interrupt.

### 26.3.1.5 Checks on Guest Non-Register State

The following checks are performed on fields in the guest-state area corresponding to non-register state:

- Activity state.
  - — The activity-state field must contain a value in the range 0 – 3, indicating an activity state supported by the implementation (see Section 24.4.2). Future processors may include support for other activity states. Software should read the VMX capability MSR IA32_VMX_MISC (see Appendix A.6) to determine what activity states are supported.
  - — The activity-state field must not indicate the HLT state if the DPL (bits 6:5) in the access-rights field for SS is not 0.[1]
  - — The activity-state field must indicate the active state if the interruptibility-state field indicates blocking by either MOV-SS or by STI (if either bit 0 or bit 1 in that field is 1).
  - — If the valid bit (bit 31) in the VM-entry interruption-information field is 1, the interruption to be delivered (as defined by interruption type and vector) must not be one that would normally be blocked while a logical processor is in the activity state corresponding to the contents of the activity-state field. The following items enumerate the interruptions (as specified in the VM-entry interruption-information field) whose injection is allowed for the different activity states:
    - Active. Any interruption is allowed.
    - HLT. The only events allowed are the following:
      - — Those with interruption type external interrupt or non-maskable interrupt (NMI).
      - — Those with interruption type hardware exception and vector 1 (debug exception) or vector 18 (machine-check exception).
      - — Those with interruption type other event and vector 0 (pending MTF VM exit).

      See Table 24-13 in Section 24.8.3 for details regarding the format of the VM-entry interruption-information field.
    - Shutdown. Only NMIs and machine-check exceptions are allowed.
    - Wait-for-SIPI. No interruptions are allowed.
  - — The activity-state field must not indicate the wait-for-SIPI state if the "entry to SMM" VM-entry control is 1.
- Interruptibility state.
  - — The reserved bits (bits 31:4) must be 0.
  - — The field cannot indicate blocking by both STI and MOV SS (bits 0 and 1 cannot both be 1).
  - — Bit 0 (blocking by STI) must be 0 if the IF flag (bit 9) is 0 in the RFLAGS field.
  - — Bit 0 (blocking by STI) and bit 1 (blocking by MOV-SS) must both be 0 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) in that field has value 0, indicating external interrupt.
  - — Bit 1 (blocking by MOV-SS) must be 0 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) in that field has value 2, indicating non-maskable interrupt (NMI).
  - — Bit 2 (blocking by SMI) must be 0 if the processor is not in SMM.
  - — Bit 2 (blocking by SMI) must be 1 if the "entry to SMM" VM-entry control is 1.

---

2. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PE must be 1 in VMX operation, bit 0 in the CR0 field must be 1 unless the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
1. As noted in Section 24.4.1, SS.DPL corresponds to the logical processor's current privilege level (CPL).

— A processor may require bit 0 (blocking by STI) to be 0 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) in that field has value 2, indicating NMI. Other processors may not make this requirement.

— Bit 3 (blocking by NMI) must be 0 if the "virtual NMIs" VM-execution control is 1, the valid bit (bit 31) in the VM-entry interruption-information field is 1, and the interruption type (bits 10:8) in that field has value 2 (indicating NMI).

**NOTE**

If the "virtual NMIs" VM-execution control is 0, there is no requirement that bit 3 be 0 if the valid bit in the VM-entry interruption-information field is 1 and the interruption type in that field has value 2.

- Pending debug exceptions.
  — Bits 11:4, bit 13, and bits 63:15 (bits 31:15 on processors that do not support Intel 64 architecture) must be 0.
  — The following checks are performed if any of the following holds: (1) the interruptibility-state field indicates blocking by STI (bit 0 in that field is 1); (2) the interruptibility-state field indicates blocking by MOV SS (bit 1 in that field is 1); or (3) the activity-state field indicates HLT:
    - Bit 14 (BS) must be 1 if the TF flag (bit 8) in the RFLAGS field is 1 and the BTF flag (bit 1) in the IA32_DEBUGCTL field is 0.
    - Bit 14 (BS) must be 0 if the TF flag (bit 8) in the RFLAGS field is 0 or the BTF flag (bit 1) in the IA32_DEBUGCTL field is 1.
- VMCS link pointer. The following checks apply if the field contains a value other than FFFFFFFF_FFFFFFFFH:
  — Bits 11:0 must be 0.
  — Bits beyond the processor's physical-address width must be 0.[1,2]
  — The 4 bytes located in memory referenced by the value of the field (as a physical address) must satisfy the following:
    - Bits 30:0 must contain the processor's VMCS revision identifier (see Section 24.2).[3]
    - Bit 31 must contain the setting of the "VMCS shadowing" VM-execution control.[4] This implies that the referenced VMCS is a shadow VMCS (see Section 24.10) if and only if the "VMCS shadowing" VM-execution control is 1.
  — If the processor is not in SMM or the "entry to SMM" VM-entry control is 1, the field must not contain the current VMCS pointer.
  — If the processor is in SMM and the "entry to SMM" VM-entry control is 0, the field must differ from the executive-VMCS pointer.

### 26.3.1.6 Checks on Guest Page-Directory-Pointer-Table Entries

If CR0.PG =1, CR4.PAE = 1, and IA32_EFER.LMA = 0, the logical processor also uses **PAE paging** (see Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*).[5] When PAE paging is in use, the physical address in CR3 references a table of **page-directory-pointer-table entries** (PDPTEs). A MOV to CR3 when PAE paging is in use checks the validity of the PDPTEs.

1. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
2. If IA32_VMX_BASIC[48] is read as 1, this field must not set any bits in the range 63:32; see Appendix A.1.
3. Earlier versions of this manual specified that the VMCS revision identifier was a 32-bit field. For all processors produced prior to this change, bit 31 of the VMCS revision identifier was 0.
4. "VMCS shadowing" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "VMCS shadowing" VM-execution control were 0. See Section 24.6.2.

A VM entry is to a guest that uses PAE paging if (1) bit 31 (corresponding to CR0.PG) is set in the CR0 field in the guest-state area; (2) bit 5 (corresponding to CR4.PAE) is set in the CR4 field; and (3) the "IA-32e mode guest" VM-entry control is 0. Such a VM entry checks the validity of the PDPTEs:

- If the "enable EPT" VM-execution control is 0, VM entry checks the validity of the PDPTEs referenced by the CR3 field in the guest-state area if either (1) PAE paging was not in use before the VM entry; or (2) the value of CR3 is changing as a result of the VM entry. VM entry may check their validity even if neither (1) nor (2) hold.[1]
- If the "enable EPT" VM-execution control is 1, VM entry checks the validity of the PDPTE fields in the guest-state area (see Section 24.4.2).

A VM entry to a guest that does not use PAE paging does not check the validity of any PDPTEs.

A VM entry that checks the validity of the PDPTEs uses the same checks that are used when CR3 is loaded with MOV to CR3 when PAE paging is in use.[2] If MOV to CR3 would cause a general-protection exception due to the PDPTEs that would be loaded (e.g., because a reserved bit is set), the VM entry fails.

## 26.3.2 Loading Guest State

Processor state is updated on VM entries in the following ways:

- Some state is loaded from the guest-state area.
- Some state is determined by VM-entry controls.
- The page-directory pointers are loaded based on the values of certain control registers.

This loading may be performed in any order and in parallel with the checking of VMCS contents (see Section 26.3.1).

The loading of guest state is detailed in Section 26.3.2.1 to Section 26.3.2.4. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the guest-state area.

In addition to the state loading described in this section, VM entries may load MSRs from the VM-entry MSR-load area (see Section 26.4). This loading occurs only after the state loading described in this section and the checking of VMCS contents described in Section 26.3.1.

### 26.3.2.1 Loading Guest Control Registers, Debug Registers, and MSRs

The following items describe how guest control registers, debug registers, and MSRs are loaded on VM entry:

- CR0 is loaded from the CR0 field with the exception of the following bits, which are never modified on VM entry: ET (bit 4); reserved bits 15:6, 17, and 28:19; NW (bit 29) and CD (bit 30).[3] The values of these bits in the CR0 field are ignored.
- CR3 and CR4 are loaded from the CR3 field and the CR4 field, respectively.
- If the "load debug controls" VM-entry control is 1, DR7 is loaded from the DR7 field with the exception that bit 12 and bits 15:14 are always 0 and bit 10 is always 1. The values of these bits in the DR7 field are ignored.

  The first processors to support the virtual-machine extensions supported only the 1-setting of the "load debug controls" VM-entry control and thus always loaded DR7 from the DR7 field.

---

5. On processors that support Intel 64 architecture, the physical-address extension may support more than 36 physical-address bits. Software can determine the number physical-address bits supported by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

1. "Enable EPT" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "enable EPT" VM-execution control were 0. See Section 24.6.2.
2. This implies that (1) bits 11:9 in each PDPTE are ignored; and (2) if bit 0 (present) is clear in one of the PDPTEs, bits 63:1 of that PDPTE are ignored.
3. Bits 15:6, bit 17, and bit 28:19 of CR0 and CR0.ET are unchanged by executions of MOV to CR0. Bits 15:6, bit 17, and bit 28:19 of CR0 are always 0 and CR0.ET is always 1.

- The following describes how some MSRs are loaded using fields in the guest-state area:
  - If the "load debug controls" VM-entry control is 1, the IA32_DEBUGCTL MSR is loaded from the IA32_DEBUGCTL field. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus always loaded the IA32_DEBUGCTL MSR from the IA32_DEBUGCTL field.
  - The IA32_SYSENTER_CS MSR is loaded from the IA32_SYSENTER_CS field. Since this field has only 32 bits, bits 63:32 of the MSR are cleared to 0.
  - The IA32_SYSENTER_ESP and IA32_SYSENTER_EIP MSRs are loaded from the IA32_SYSENTER_ESP field and the IA32_SYSENTER_EIP field, respectively. On processors that do not support Intel 64 architecture, these fields have only 32 bits; bits 63:32 of the MSRs are cleared to 0.
  - The following are performed on processors that support Intel 64 architecture:
    - The MSRs FS.base and GS.base are loaded from the base-address fields for FS and GS, respectively (see Section 26.3.2.2).
    - If the "load IA32_EFER" VM-entry control is 0, bits in the IA32_EFER MSR are modified as follows:
      - IA32_EFER.LMA is loaded with the setting of the "IA-32e mode guest" VM-entry control.
      - If CR0 is being loaded so that CR0.PG = 1, IA32_EFER.LME is also loaded with the setting of the "IA-32e mode guest" VM-entry control.[1] Otherwise, IA32_EFER.LME is unmodified.

      See below for the case in which the "load IA32_EFER" VM-entry control is 1
  - If the "load IA32_PERF_GLOBAL_CTRL" VM-entry control is 1, the IA32_PERF_GLOBAL_CTRL MSR is loaded from the IA32_PERF_GLOBAL_CTRL field.
  - If the "load IA32_PAT" VM-entry control is 1, the IA32_PAT MSR is loaded from the IA32_PAT field.
  - If the "load IA32_EFER" VM-entry control is 1, the IA32_EFER MSR is loaded from the IA32_EFER field.

  With the exception of FS.base and GS.base, any of these MSRs is subsequently overwritten if it appears in the VM-entry MSR-load area. See Section 26.4.
- The SMBASE register is unmodified by all VM entries except those that return from SMM.

### 26.3.2.2 Loading Guest Segment Registers and Descriptor-Table Registers

For each of CS, SS, DS, ES, FS, GS, TR, and LDTR, fields are loaded from the guest-state area as follows:

- The unusable bit is loaded from the access-rights field. This bit can never be set for TR (see Section 26.3.1.2). If it is set for one of the other registers, the following apply:
  - For each of CS, SS, DS, ES, FS, and GS, uses of the segment cause faults (general-protection exception or stack-fault exception) outside 64-bit mode, just as they would had the segment been loaded using a null selector. This bit does not cause accesses to fault in 64-bit mode.
  - If this bit is set for LDTR, uses of LDTR cause general-protection exceptions in all modes, just as they would had LDTR been loaded using a null selector.

  If this bit is clear for any of CS, SS, DS, ES, FS, GS, TR, and LDTR, a null selector value does not cause a fault (general-protection exception or stack-fault exception).
- TR. The selector, base, limit, and access-rights fields are loaded.
- CS.
  - The following fields are always loaded: selector, base address, limit, and (from the access-rights field) the L, D, and G bits.
  - For the other fields, the unusable bit of the access-rights field is consulted:
    - If the unusable bit is 0, all of the access-rights field is loaded.
    - If the unusable bit is 1, the remainder of CS access rights are undefined after VM entry.

1. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PG must be 1 in VMX operation, VM entry must be loading CR0 so that CR0.PG = 1 unless the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

- SS, DS, ES, FS, GS, and LDTR.
  - The selector fields are loaded.
  - For the other fields, the unusable bit of the corresponding access-rights field is consulted:
    - If the unusable bit is 0, the base-address, limit, and access-rights fields are loaded.
    - If the unusable bit is 1, the base address, the segment limit, and the remainder of the access rights are undefined after VM entry with the following exceptions:
      - Bits 3:0 of the base address for SS are cleared to 0.
      - SS.DPL is always loaded from the SS access-rights field. This will be the current privilege level (CPL) after the VM entry completes.
      - SS.B is always set to 1.
      - The base addresses for FS and GS are loaded from the corresponding fields in the VMCS. On processors that support Intel 64 architecture, the values loaded for base addresses for FS and GS are also manifest in the FS.base and GS.base MSRs.
      - On processors that support Intel 64 architecture, the base address for LDTR is set to an undefined but canonical value.
      - On processors that support Intel 64 architecture, bits 63:32 of the base addresses for SS, DS, and ES are cleared to 0.

GDTR and IDTR are loaded using the base and limit fields.

### 26.3.2.3 Loading Guest RIP, RSP, and RFLAGS

RSP, RIP, and RFLAGS are loaded from the RSP field, the RIP field, and the RFLAGS field, respectively. The following items regard the upper 32 bits of these fields on VM entries that are not to 64-bit mode:

- Bits 63:32 of RSP are undefined outside 64-bit mode. Thus, a logical processor may ignore the contents of bits 63:32 of the RSP field on VM entries that are not to 64-bit mode.
- As noted in Section 26.3.1.4, bits 63:32 of the RIP and RFLAGS fields must be 0 on VM entries that are not to 64-bit mode.

### 26.3.2.4 Loading Page-Directory-Pointer-Table Entries

As noted in Section 26.3.1.6, the logical processor uses PAE paging if bit 5 in CR4 (CR4.PAE) is 1 and IA32_EFER.LMA is 0. A VM entry to a guest that uses PAE paging loads the PDPTEs into internal, non-architectural registers based on the setting of the "enable EPT" VM-execution control:

- If the control is 0, the PDPTEs are loaded from the page-directory-pointer table referenced by the physical address in the value of CR3 being loaded by the VM entry (see Section 26.3.2.1). The values loaded are treated as physical addresses in VMX non-root operation.
- If the control is 1, the PDPTEs are loaded from corresponding fields in the guest-state area (see Section 24.4.2). The values loaded are treated as guest-physical addresses in VMX non-root operation.

### 26.3.2.5 Updating Non-Register State

Section 28.3 describes how the VMX architecture controls how a logical processor manages information in the TLBs and paging-structure caches. The following items detail how VM entries invalidate cached mappings:

- If the "enable VPID" VM-execution control is 0, the logical processor invalidates linear mappings and combined mappings associated with VPID 0000H (for all PCIDs); combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP).
- VM entries are not required to invalidate any guest-physical mappings, nor are they required to invalidate any linear mappings or combined mappings if the "enable VPID" VM-execution control is 1.

If the "virtual-interrupt delivery" VM-execution control is 1, VM entry loads the values of RVI and SVI from the guest interrupt-status field in the VMCS (see Section 24.4.2). After doing so, the logical processor first causes PPR virtualization (Section 29.1.3) and then evaluates pending virtual interrupts (Section 29.2.1).

If a virtual interrupt is recognized, it may be delivered in VMX non-root operation immediately after VM entry (including any specified event injection) completes; see Section 26.6.5. See Section 29.2.2 for details regarding the delivery of virtual interrupts.

### 26.3.3 Clearing Address-Range Monitoring

The Intel 64 and IA-32 architectures allow software to monitor a specified address range using the MONITOR and MWAIT instructions. See Section 8.10.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*. VM entries clear any address-range monitoring that may be in effect.

## 26.4 LOADING MSRS

VM entries may load MSRs from the VM-entry MSR-load area (see Section 24.8.2). Specifically each entry in that area (up to the number specified in the VM-entry MSR-load count) is processed in order by loading the MSR indexed by bits 31:0 with the contents of bits 127:64 as they would be written by WRMSR.[1]

Processing of an entry fails in any of the following cases:

- The value of bits 31:0 is either C0000100H (the IA32_FS_BASE MSR) or C0000101 (the IA32_GS_BASE MSR).
- The value of bits 31:8 is 000008H, meaning that the indexed MSR is one that allows access to an APIC register when the local APIC is in x2APIC mode.
- The value of bits 31:0 indicates an MSR that can be written only in system-management mode (SMM) and the VM entry did not commence in SMM. (IA32_SMM_MONITOR_CTL is an MSR that can be written only in SMM.)
- The value of bits 31:0 indicates an MSR that cannot be loaded on VM entries for model-specific reasons. A processor may prevent loading of certain MSRs even if they can normally be written by WRMSR. Such model-specific behavior is documented in Chapter 35.
- Bits 63:32 are not all 0.
- An attempt to write bits 127:64 to the MSR indexed by bits 31:0 of the entry would cause a general-protection exception if executed via WRMSR with CPL = 0.[2]

The VM entry fails if processing fails for any entry. The logical processor responds to such failures by loading state from the host-state area, as it would for a VM exit. See Section 26.7.

If any MSR is being loaded in such a way that would architecturally require a TLB flush, the TLBs are updated so that, after VM entry, the logical processor will not use any translations that were cached before the transition.

## 26.5 EVENT INJECTION

If the valid bit in the VM-entry interruption-information field (see Section 24.8.3) is 1, VM entry causes an event to be delivered (or made pending) after all components of guest state have been loaded (including MSRs) and after the VM-execution control fields have been established.

- If the interruption type in the field is 0 (external interrupt), 2 (non-maskable interrupt); 3 (hardware exception), 4 (software interrupt), 5 (privileged software exception), or 6 (software exception), the event is delivered as described in Section 26.5.1.

---

1. Because attempts to modify the value of IA32_EFER.LMA by WRMSR are ignored, attempts to modify it using the VM-entry MSR-load area are also ignored.
2. If CR0.PG = 1, WRMSR to the IA32_EFER MSR causes a general-protection exception if it would modify the LME bit. If VM entry has established CR0.PG = 1, the IA32_EFER MSR should not be included in the VM-entry MSR-load area for the purpose of modifying the LME bit.

- If the interruption type in the field is 7 (other event) and the vector field is 0, an MTF VM exit is pending after VM entry. See Section 26.5.2.

## 26.5.1 Vectored-Event Injection

VM entry delivers an injected vectored event within the guest context established by VM entry. This means that delivery occurs after all components of guest state have been loaded (including MSRs) and after the VM-execution control fields have been established.[1] The event is delivered using the vector in that field to select a descriptor in the IDT. Since event injection occurs after loading IDTR from the guest-state area, this is the guest IDT.

Section 26.5.1.1 provides details of vectored-event injection. In general, the event is delivered exactly as if it had been generated normally.

If event delivery encounters a nested exception (for example, a general-protection exception because the vector indicates a descriptor beyond the IDT limit), the exception bitmap is consulted using the vector of that exception:

- If the bit for the nested exception is 0, the nested exception is delivered normally. If the nested exception is benign, it is delivered through the IDT. If it is contributory or a page fault, a double fault may be generated, depending on the nature of the event whose delivery encountered the nested exception. See Chapter 6, "Interrupt 8—Double Fault Exception (#DF)" in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.[2]
- If the bit for the nested exception is 1, a VM exit occurs. Section 26.5.1.2 details cases in which event injection causes a VM exit.

### 26.5.1.1 Details of Vectored-Event Injection

The event-injection process is controlled by the contents of the VM-entry interruption information field (format given in Table 24-13), the VM-entry exception error-code field, and the VM-entry instruction-length field. The following items provide details of the process:

- The value pushed on the stack for RFLAGS is generally that which was loaded from the guest-state area. The value pushed for the RF flag is not modified based on the type of event being delivered. However, the pushed value of RFLAGS may be modified if a software interrupt is being injected into a guest that will be in virtual-8086 mode (see below). After RFLAGS is pushed on the stack, the value in the RFLAGS register is modified as is done normally when delivering an event through the IDT.
- The instruction pointer that is pushed on the stack depends on the type of event and whether nested exceptions occur during its delivery. The term **current guest RIP** refers to the value to be loaded from the guest-state area. The value pushed is determined as follows:[3]
  - If VM entry successfully injects (with no nested exception) an event with interruption type external interrupt, NMI, or hardware exception, the current guest RIP is pushed on the stack.
  - If VM entry successfully injects (with no nested exception) an event with interruption type software interrupt, privileged software exception, or software exception, the current guest RIP is incremented by the VM-entry instruction length before being pushed on the stack.
  - If VM entry encounters an exception while injecting an event and that exception does not cause a VM exit, the current guest RIP is pushed on the stack regardless of event type or VM-entry instruction length. If the encountered exception does cause a VM exit that saves RIP, the saved RIP is current guest RIP.
- If the deliver-error-code bit (bit 11) is set in the VM-entry interruption-information field, the contents of the VM-entry exception error-code field is pushed on the stack as an error code would be pushed during delivery of an exception.

1. This does not imply that injection of an exception or interrupt will cause a VM exit due to the settings of VM-execution control fields (such as the exception bitmap) that would cause a VM exit if the event had occurred in VMX non-root operation. In contrast, a nested exception encountered during event delivery may cause a VM exit; see Section 26.5.1.1.
2. Hardware exceptions with the following unused vectors are considered benign: 15 and 21–31. A hardware exception with vector 20 is considered benign unless the processor supports the 1-setting of the "EPT-violation #VE" VM-execution control; in that case, it has the same severity as page faults.
3. While these items refer to RIP, the width of the value pushed (16 bits, 32 bits, or 64 bits) is determined normally.

- DR6, DR7, and the IA32_DEBUGCTL MSR are not modified by event injection, even if the event has vector 1 (normal deliveries of debug exceptions, which have vector 1, do update these registers).
- If VM entry is injecting a software interrupt and the guest will be in virtual-8086 mode (RFLAGS.VM = 1), no general-protection exception can occur due to RFLAGS.IOPL < 3. A VM monitor should check RFLAGS.IOPL before injecting such an event and, if desired, inject a general-protection exception instead of a software interrupt.
- If VM entry is injecting a software interrupt and the guest will be in virtual-8086 mode with virtual-8086 mode extensions (RFLAGS.VM = CR4.VME = 1), event delivery is subject to VME-based interrupt redirection based on the software interrupt redirection bitmap in the task-state segment (TSS) as follows:
  - If bit *n* in the bitmap is clear (where *n* is the number of the software interrupt), the interrupt is directed to an 8086 program interrupt handler: the processor uses a 16-bit interrupt-vector table (IVT) located at linear address zero. If the value of RFLAGS.IOPL is less than 3, the following modifications are made to the value of RFLAGS that is pushed on the stack: IOPL is set to 3, and IF is set to the value of VIF.
  - If bit *n* in the bitmap is set (where *n* is the number of the software interrupt), the interrupt is directed to a protected-mode interrupt handler. (In other words, the injection is treated as described in the next item.) In this case, the software interrupt does not invoke such a handler if RFLAGS.IOPL < 3 (a general-protection exception occurs instead). However, as noted above, RFLAGS.IOPL cannot cause an injected software interrupt to cause such a exception. Thus, in this case, the injection invokes a protected-mode interrupt handler independent of the value of RFLAGS.IOPL.

  Injection of events of other types are not subject to this redirection.
- If VM entry is injecting a software interrupt (not redirected as described above) or software exception, privilege checking is performed on the IDT descriptor being accessed as would be the case for executions of INT *n*, INT3, or INTO (the descriptor's DPL cannot be less than CPL). There is no checking of RFLAGS.IOPL, even if the guest will be in virtual-8086 mode. Failure of this check may lead to a nested exception. Injection of an event with interruption type external interrupt, NMI, hardware exception, and privileged software exception, or with interruption type software interrupt and being redirected as described above, do not perform these checks.
- If VM entry is injecting a non-maskable interrupt (NMI) and the "virtual NMIs" VM-execution control is 1, virtual-NMI blocking is in effect after VM entry.
- The transition causes a last-branch record to be logged if the LBR bit is set in the IA32_DEBUGCTL MSR. This is true even for events such as debug exceptions, which normally clear the LBR bit before delivery.
- The last-exception record MSRs (LERs) may be updated based on the setting of the LBR bit in the IA32_DEBUGCTL MSR. Events such as debug exceptions, which normally clear the LBR bit before they are delivered, and therefore do not normally update the LERs, may do so as part of VM-entry event injection.
- If injection of an event encounters a nested exception that does not itself cause a VM exit, the value of the EXT bit (bit 0) in any error code pushed on the stack is determined as follows:
  - If event being injected has interruption type external interrupt, NMI, hardware exception, or privileged software exception and encounters a nested exception (but does not produce a double fault), the error code for the first such exception encountered sets the EXT bit.
  - If event being injected is a software interrupt or an software exception and encounters a nested exception (but does not produce a double fault), the error code for the first such exception encountered clears the EXT bit.
  - If event delivery encounters a nested exception and delivery of that exception encounters another exception (but does not produce a double fault), the error code for that exception sets the EXT bit. If a double fault is produced, the error code for the double fault is 0000H (the EXT bit is clear).

#### 26.5.1.2 VM Exits During Event Injection

An event being injected never causes a VM exit directly regardless of the settings of the VM-execution controls. For example, setting the "NMI exiting" VM-execution control to 1 does not cause a VM exit due to injection of an NMI.

However, the event-delivery process may lead to a VM exit:

- If the vector in the VM-entry interruption-information field identifies a task gate in the IDT, the attempted task switch may cause a VM exit just as it would had the injected event occurred during normal execution in VMX non-root operation (see Section 25.4.2).
- If event delivery encounters a nested exception, a VM exit may occur depending on the contents of the exception bitmap (see Section 25.2).
- If event delivery generates a double-fault exception (due to a nested exception); the logical processor encounters another nested exception while attempting to call the double-fault handler; and that exception does not cause a VM exit due to the exception bitmap; then a VM exit occurs due to triple fault (see Section 25.2).
- If event delivery injects a double-fault exception and encounters a nested exception that does not cause a VM exit due to the exception bitmap, then a VM exit occurs due to triple fault (see Section 25.2).
- If the "virtualize APIC accesses" VM-execution control is 1 and event delivery generates an access to the APIC-access page, that access is treated as described in Section 29.4 and may cause a VM exit.[1]

If the event-delivery process does cause a VM exit, the processor state before the VM exit is determined just as it would be had the injected event occurred during normal execution in VMX non-root operation. If the injected event directly accesses a task gate that cause a VM exit or if the first nested exception encountered causes a VM exit, information about the injected event is saved in the IDT-vectoring information field (see Section 27.2.3).

#### 26.5.1.3 Event Injection for VM Entries to Real-Address Mode

If VM entry is loading CR0.PE with 0, any injected vectored event is delivered as would normally be done in real-address mode.[2] Specifically, VM entry uses the vector provided in the VM-entry interruption-information field to select a 4-byte entry from an interrupt-vector table at the linear address in IDTR.base. Further details are provided in Section 15.1.4 in Volume 3A of the *IA-32 Intel® Architecture Software Developer's Manual*.

Because bit 11 (deliver error code) in the VM-entry interruption-information field must be 0 if CR0.PE will be 0 after VM entry (see Section 26.2.1.3), vectored events injected with CR0.PE = 0 do not push an error code on the stack. This is consistent with event delivery in real-address mode.

If event delivery encounters a fault (due to a violation of IDTR.limit or of SS.limit), the fault is treated as if it had occurred during event delivery in VMX non-root operation. Such a fault may lead to a VM exit as discussed in Section 26.5.1.2.

### 26.5.2 Injection of Pending MTF VM Exits

If the interruption type in the VM-entry interruption-information field is 7 (other event) and the vector field is 0, VM entry causes an MTF VM exit to be pending on the instruction boundary following VM entry. This is the case even if the "monitor trap flag" VM-execution control is 0. See Section 25.5.2 for the treatment of pending MTF VM exits.

## 26.6 SPECIAL FEATURES OF VM ENTRY

This section details a variety of features of VM entry. It uses the following terminology: a VM entry is **vectoring** if the valid bit (bit 31) of the VM-entry interruption information field is 1 and the interruption type in the field is 0 (external interrupt), 2 (non-maskable interrupt); 3 (hardware exception), 4 (software interrupt), 5 (privileged software exception), or 6 (software exception).

1. "Virtualize APIC accesses" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "virtualize APIC accesses" VM-execution control were 0. See Section 24.6.2.
2. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PE must be 1 in VMX operation, VM entry must be loading CR0.PE with 1 unless the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

### 26.6.1 Interruptibility State

The interruptibility-state field in the guest-state area (see Table 24-3) contains bits that control blocking by STI, blocking by MOV SS, and blocking by NMI. This field impacts event blocking after VM entry as follows:

- If the VM entry is vectoring, there is no blocking by STI or by MOV SS following the VM entry, regardless of the contents of the interruptibility-state field.
- If the VM entry is not vectoring, the following apply:
  - Events are blocked by STI if and only if bit 0 in the interruptibility-state field is 1. This blocking is cleared after the guest executes one instruction or incurs an exception (including a debug exception made pending by VM entry; see Section 26.6.3).
  - Events are blocked by MOV SS if and only if bit 1 in the interruptibility-state field is 1. This may affect the treatment of pending debug exceptions; see Section 26.6.3. This blocking is cleared after the guest executes one instruction or incurs an exception (including a debug exception made pending by VM entry).
- The blocking of non-maskable interrupts (NMIs) is determined as follows:
  - If the "virtual NMIs" VM-execution control is 0, NMIs are blocked if and only if bit 3 (blocking by NMI) in the interruptibility-state field is 1. If the "NMI exiting" VM-execution control is 0, execution of the IRET instruction removes this blocking (even if the instruction generates a fault). If the "NMI exiting" control is 1, IRET does not affect this blocking.
  - The following items describe the use of bit 3 (blocking by NMI) in the interruptibility-state field if the "virtual NMIs" VM-execution control is 1:
    - The bit's value does not affect the blocking of NMIs after VM entry. NMIs are not blocked in VMX non-root operation (except for ordinary blocking for other reasons, such as by the MOV SS instruction, the wait-for-SIPI state, etc.)
    - The bit's value determines whether there is virtual-NMI blocking after VM entry. If the bit is 1, virtual-NMI blocking is in effect after VM entry. If the bit is 0, there is no virtual-NMI blocking after VM entry unless the VM entry is injecting an NMI (see Section 26.5.1.1). Execution of IRET removes virtual-NMI blocking (even if the instruction generates a fault).

  If the "NMI exiting" VM-execution control is 0, the "virtual NMIs" control must be 0; see Section 26.2.1.1.
- Blocking of system-management interrupts (SMIs) is determined as follows:
  - If the VM entry was not executed in system-management mode (SMM), SMI blocking is unchanged by VM entry.
  - If the VM entry was executed in SMM, SMIs are blocked after VM entry if and only if the bit 2 in the interruptibility-state field is 1.

### 26.6.2 Activity State

The activity-state field in the guest-state area controls whether, after VM entry, the logical processor is active or in one of the inactive states identified in Section 24.4.2. The use of this field is determined as follows:

- If the VM entry is vectoring, the logical processor is in the active state after VM entry. While the consistency checks described in Section 26.3.1.5 on the activity-state field do apply in this case, the contents of the activity-state field do not determine the activity state after VM entry.
- If the VM entry is not vectoring, the logical processor ends VM entry in the activity state specified in the guest-state area. If VM entry ends with the logical processor in an inactive activity state, the VM entry generates any special bus cycle that is normally generated when that activity state is entered from the active state. If VM entry would end with the logical processor in the shutdown state and the logical processor is in SMX operation,[1] an Intel® TXT shutdown condition occurs. The error code used is 0000H, indicating "legacy shutdown." See *Intel® Trusted Execution Technology Preliminary Architecture Specification*.

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.

- Some activity states unconditionally block certain events. The following blocking is in effect after any VM entry that puts the processor in the indicated state:
  - The active state blocks start-up IPIs (SIPIs). SIPIs that arrive while a logical processor is in the active state and in VMX non-root operation are discarded and do not cause VM exits.
  - The HLT state blocks start-up IPIs (SIPIs). SIPIs that arrive while a logical processor is in the HLT state and in VMX non-root operation are discarded and do not cause VM exits.
  - The shutdown state blocks external interrupts and SIPIs. External interrupts that arrive while a logical processor is in the shutdown state and in VMX non-root operation do not cause VM exits even if the "external-interrupt exiting" VM-execution control is 1. SIPIs that arrive while a logical processor is in the shutdown state and in VMX non-root operation are discarded and do not cause VM exits.
  - The wait-for-SIPI state blocks external interrupts, non-maskable interrupts (NMIs), INIT signals, and system-management interrupts (SMIs). Such events do not cause VM exits if they arrive while a logical processor is in the wait-for-SIPI state and in VMX non-root operation do not cause VM exits regardless of the settings of the pin-based VM-execution controls.

## 26.6.3 Delivery of Pending Debug Exceptions after VM Entry

The pending debug exceptions field in the guest-state area indicates whether there are debug exceptions that have not yet been delivered (see Section 24.4.2). This section describes how these are treated on VM entry.

There are no pending debug exceptions after VM entry if any of the following are true:

- The VM entry is vectoring with one of the following interruption types: external interrupt, non-maskable interrupt (NMI), hardware exception, or privileged software exception.
- The interruptibility-state field does not indicate blocking by MOV SS and the VM entry is vectoring with either of the following interruption type: software interrupt or software exception.
- The VM entry is not vectoring and the activity-state field indicates either shutdown or wait-for-SIPI.

If none of the above hold, the pending debug exceptions field specifies the debug exceptions that are pending for the guest. There are **valid pending debug exceptions** if either the BS bit (bit 14) or the enable-breakpoint bit (bit 12) is 1. If there are valid pending debug exceptions, they are handled as follows:

- If the VM entry is not vectoring, the pending debug exceptions are treated as they would had they been encountered normally in guest execution:
  - If the logical processor is not blocking such exceptions (the interruptibility-state field indicates no blocking by MOV SS), a debug exception is delivered after VM entry (see below).
  - If the logical processor is blocking such exceptions (due to blocking by MOV SS), the pending debug exceptions are held pending or lost as would normally be the case.
- If the VM entry is vectoring (with interruption type software interrupt or software exception and with blocking by MOV SS), the following items apply:
  - For injection of a software interrupt or of a software exception with vector 3 (#BP) or vector 4 (#OF), the pending debug exceptions are treated as they would had they been encountered normally in guest execution if the corresponding instruction (INT3 or INTO) were executed after a MOV SS that encountered a debug trap.
  - For injection of a software exception with a vector other than 3 and 4, the pending debug exceptions may be lost or they may be delivered after injection (see below).

If there are no valid pending debug exceptions (as defined above), no pending debug exceptions are delivered after VM entry.

If a pending debug exception is delivered after VM entry, it has the priority of "traps on the previous instruction" (see Section 6.9 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*). Thus, INIT signals and system-management interrupts (SMIs) take priority of such an exception, as do VM exits induced by the TPR threshold (see Section 26.6.7) and pending MTF VM exits (see Section 26.6.8. The exception takes priority over any pending non-maskable interrupt (NMI) or external interrupt and also over VM exits due to the 1-settings of the "interrupt-window exiting" and "NMI-window exiting" VM-execution controls.

A pending debug exception delivered after VM entry causes a VM exit if the bit 1 (#DB) is 1 in the exception bitmap. If it does not cause a VM exit, it updates DR6 normally.

### 26.6.4 VMX-Preemption Timer

If the "activate VMX-preemption timer" VM-execution control is 1, VM entry starts the VMX-preemption timer with the unsigned value in the VMX-preemption timer-value field.

It is possible for the VMX-preemption timer to expire during VM entry (e.g., if the value in the VMX-preemption timer-value field is zero). If this happens (and if the VM entry was not to the wait-for-SIPI state), a VM exit occurs with its normal priority after any event injection and before execution of any instruction following VM entry. For example, any pending debug exceptions established by VM entry (see Section 26.6.3) take priority over a timer-induced VM exit. (The timer-induced VM exit will occur after delivery of the debug exception, unless that exception or its delivery causes a different VM exit.)

See Section 25.5.1 for details of the operation of the VMX-preemption timer in VMX non-root operation, including the blocking and priority of the VM exits that it causes.

### 26.6.5 Interrupt-Window Exiting and Virtual-Interrupt Delivery

If "interrupt-window exiting" VM-execution control is 1, an open interrupt window may cause a VM exit immediately after VM entry (see Section 25.2 for details). If the "interrupt-window exiting" VM-execution control is 0 but the "virtual-interrupt delivery" VM-execution control is 1, a virtual interrupt may be delivered immediately after VM entry (see Section 26.3.2.5 and Section 29.2.1).

The following items detail the treatment of these events:

- These events occur after any event injection specified for VM entry.
- Non-maskable interrupts (NMIs) and higher priority events take priority over these events. These events take priority over external interrupts and lower priority events.
- These events wake the logical processor if it just entered the HLT state because of a VM entry (see Section 26.6.2). They do not occur if the logical processor just entered the shutdown state or the wait-for-SIPI state.

### 26.6.6 NMI-Window Exiting

The "NMI-window exiting" VM-execution control may cause a VM exit to occur immediately after VM entry (see Section 25.2 for details).

The following items detail the treatment of these VM exits:

- These VM exits follow event injection if such injection is specified for VM entry.
- Debug-trap exceptions (see Section 26.6.3) and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over non-maskable interrupts (NMIs) and lower priority events.
- VM exits caused by this control wake the logical processor if it just entered either the HLT state or the shutdown state because of a VM entry (see Section 26.6.2). They do not occur if the logical processor just entered the wait-for-SIPI state.

### 26.6.7 VM Exits Induced by the TPR Threshold

If the "use TPR shadow" and "virtualize APIC accesses" VM-execution controls are both 1 and the "virtual-interrupt delivery" VM-execution control is 0, a VM exit occurs immediately after VM entry if the value of bits 3:0 of the TPR threshold VM-execution control field is greater than the value of bits 7:4 of VTPR (see Section 29.1.1).[1]

1. "Virtualize APIC accesses" and "virtual-interrupt delivery" are secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if these controls were 0. See Section 24.6.2.

The following items detail the treatment of these VM exits:

- The VM exits are not blocked if RFLAGS.IF = 0 or by the setting of bits in the interruptibility-state field in guest-state area.
- The VM exits follow event injection if such injection is specified for VM entry.
- VM exits caused by this control take priority over system-management interrupts (SMIs), INIT signals, and lower priority events. They thus have priority over the VM exits described in Section 26.6.5, Section 26.6.6, and Section 26.6.8, as well as any interrupts or debug exceptions that may be pending at the time of VM entry.
- These VM exits wake the logical processor if it just entered the HLT state as part of a VM entry (see Section 26.6.2). They do not occur if the logical processor just entered the shutdown state or the wait-for-SIPI state.

  If such a VM exit is suppressed because the processor just entered the shutdown state, it occurs after the delivery of any event that cause the logical processor to leave the shutdown state while remaining in VMX non-root operation (e.g., due to an NMI that occurs while the "NMI-exiting" VM-execution control is 0).
- The basic exit reason is "TPR below threshold."

### 26.6.8 Pending MTF VM Exits

As noted in Section 26.5.2, VM entry may cause an MTF VM exit to be pending immediately after VM entry. The following items detail the treatment of these VM exits:

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over these VM exits. These VM exits take priority over debug-trap exceptions and lower priority events.
- These VM exits wake the logical processor if it just entered the HLT state because of a VM entry (see Section 26.6.2). They do not occur if the logical processor just entered the shutdown state or the wait-for-SIPI state.

### 26.6.9 VM Entries and Advanced Debugging Features

VM entries are not logged with last-branch records, do not produce branch-trace messages, and do not update the branch-trace store.

## 26.7 VM-ENTRY FAILURES DURING OR AFTER LOADING GUEST STATE

VM-entry failures due to the checks identified in Section 26.3.1 and failures during the MSR loading identified in Section 26.4 are treated differently from those that occur earlier in VM entry. In these cases, the following steps take place:

1. Information about the VM-entry failure is recorded in the VM-exit information fields:
   - Exit reason.
     - Bits 15:0 of this field contain the basic exit reason. It is loaded with a number indicating the general cause of the VM-entry failure. The following numbers are used:

       33. VM-entry failure due to invalid guest state. A VM entry failed one of the checks identified in Section 26.3.1.

       34. VM-entry failure due to MSR loading. A VM entry failed in an attempt to load MSRs (see Section 26.4).

       41. VM-entry failure due to machine-check event. A machine-check event occurred during VM entry (see Section 26.8).
     - Bit 31 is set to 1 to indicate a VM-entry failure.
     - The remainder of the field (bits 30:16) is cleared.
   - Exit qualification. This field is set based on the exit reason.
     - VM-entry failure due to invalid guest state. In most cases, the exit qualification is cleared to 0. The following non-zero values are used in the cases indicated:

1. Not used.
2. Failure was due to a problem loading the PDPTEs (see Section 26.3.1.6).
3. Failure was due to an attempt to inject a non-maskable interrupt (NMI) into a guest that is blocking events through the STI blocking bit in the interruptibility-state field. Such failures are implementation-specific (see Section 26.3.1.5).
4. Failure was due to an invalid VMCS link pointer (see Section 26.3.1.5).

VM-entry checks on guest-state fields may be performed in any order. Thus, an indication by exit qualification of one cause does not imply that there are not also other errors. Different processors may give different exit qualifications for the same VMCS.

- VM-entry failure due to MSR loading. The exit qualification is loaded to indicate which entry in the VM-entry MSR-load area caused the problem (1 for the first entry, 2 for the second, etc.).

— All other VM-exit information fields are unmodified.

2. Processor state is loaded as would be done on a VM exit (see Section 27.5). If this results in [CR4.PAE & CR0.PG & ~IA32_EFER.LMA] = 1, page-directory-pointer-table entries (PDPTEs) may be checked and loaded (see Section 27.5.4).
3. The state of blocking by NMI is what it was before VM entry.
4. MSRs are loaded as specified in the VM-exit MSR-load area (see Section 27.6).

Although this process resembles that of a VM exit, many steps taken during a VM exit do not occur for these VM-entry failures:

- Most VM-exit information fields are not updated (see step 1 above).
- The valid bit in the VM-entry interruption-information field is not cleared.
- The guest-state area is not modified.
- No MSRs are saved into the VM-exit MSR-store area.

## 26.8 MACHINE-CHECK EVENTS DURING VM ENTRY

If a machine-check event occurs during a VM entry, one of the following occurs:

- The machine-check event is handled as if it occurred before the VM entry:
  - — If CR4.MCE = 0, operation of the logical processor depends on whether the logical processor is in SMX operation:[1]
    - If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs. The error code used is 000CH, indicating "unrecoverable machine-check condition."
    - If the logical processor is outside SMX operation, it goes to the shutdown state.
  - — If CR4.MCE = 1, a machine-check exception (#MC) is delivered through the IDT.
- The machine-check event is handled after VM entry completes:
  - — If the VM entry ends with CR4.MCE = 0, operation of the logical processor depends on whether the logical processor is in SMX operation:
    - If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs with error code 000CH (unrecoverable machine-check condition).
    - If the logical processor is outside SMX operation, it goes to the shutdown state.
  - — If the VM entry ends with CR4.MCE = 1, a machine-check exception (#MC) is generated:
    - If bit 18 (#MC) of the exception bitmap is 0, the exception is delivered through the guest IDT.

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.

    - If bit 18 of the exception bitmap is 1, the exception causes a VM exit.
- A VM-entry failure occurs as described in Section 26.7. The basic exit reason is 41, for "VM-entry failure due to machine-check event."

The first option is not used if the machine-check event occurs after any guest state has been loaded. The second option is used only if VM entry is able to load all guest state.

# CHAPTER 27
# VM EXITS

VM exits occur in response to certain instructions and events in VMX non-root operation as detailed in Section 25.1 through Section 25.2. VM exits perform the following operations:

1. Information about the cause of the VM exit is recorded in the VM-exit information fields and VM-entry control fields are modified as described in Section 27.2.
2. Processor state is saved in the guest-state area (Section 27.3).
3. MSRs may be saved in the VM-exit MSR-store area (Section 27.4). This step is not performed for SMM VM exits that activate the dual-monitor treatment of SMIs and SMM.
4. The following may be performed in parallel and in any order (Section 27.5):
   — Processor state is loaded based in part on the host-state area and some VM-exit controls. This step is not performed for SMM VM exits that activate the dual-monitor treatment of SMIs and SMM. See Section 34.15.6 for information on how processor state is loaded by such VM exits.
   — Address-range monitoring is cleared.
5. MSRs may be loaded from the VM-exit MSR-load area (Section 27.6). This step is not performed for SMM VM exits that activate the dual-monitor treatment of SMIs and SMM.

VM exits are not logged with last-branch records, do not produce branch-trace messages, and do not update the branch-trace store.

Section 27.1 clarifies the nature of the architectural state before a VM exit begins. The steps described above are detailed in Section 27.2 through Section 27.6.

Section 34.15 describes the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM). Under this treatment, ordinary transitions to SMM are replaced by VM exits to a separate SMM monitor. Called **SMM VM exits**, these are caused by the arrival of an SMI or the execution of VMCALL in VMX root operation. SMM VM exits differ from other VM exits in ways that are detailed in Section 34.15.2.

## 27.1 ARCHITECTURAL STATE BEFORE A VM EXIT

This section describes the architectural state that exists before a VM exit, especially for VM exits caused by events that would normally be delivered through the IDT. Note the following:

- An exception causes a VM exit **directly** if the bit corresponding to that exception is set in the exception bitmap. A non-maskable interrupt (NMI) causes a VM exit directly if the "NMI exiting" VM-execution control is 1. An external interrupt causes a VM exit directly if the "external-interrupt exiting" VM-execution control is 1. A start-up IPI (SIPI) that arrives while a logical processor is in the wait-for-SIPI activity state causes a VM exit directly. INIT signals that arrive while the processor is not in the wait-for-SIPI activity state cause VM exits directly.
- An exception, NMI, external interrupt, or software interrupt causes a VM exit **indirectly** if it does not do so directly but delivery of the event causes a nested exception, double fault, task switch, APIC access (see Section 27.4), EPT violation, or EPT misconfiguration that causes a VM exit.
- An event **results** in a VM exit if it causes a VM exit (directly or indirectly).

The following bullets detail when architectural state is and is not updated in response to VM exits:

- If an event causes a VM exit directly, it does not update architectural state as it would have if it had it not caused the VM exit:
  — A debug exception does not update DR6, DR7.GD, or IA32_DEBUGCTL.LBR. (Information about the nature of the debug exception is saved in the exit qualification field.)
  — A page fault does not update CR2. (The linear address causing the page fault is saved in the exit-qualification field.)
  — An NMI causes subsequent NMIs to be blocked, but only after the VM exit completes.

  - An external interrupt does not acknowledge the interrupt controller and the interrupt remains pending, unless the "acknowledge interrupt on exit" VM-exit control is 1. In such a case, the interrupt controller is acknowledged and the interrupt is no longer pending.
  - The flags L0 – L3 in DR7 (bit 0, bit 2, bit 4, and bit 6) are not cleared when a task switch causes a VM exit.
  - If a task switch causes a VM exit, none of the following are modified by the task switch: old task-state segment (TSS); new TSS; old TSS descriptor; new TSS descriptor; RFLAGS.NT[1]; or the TR register.
  - No last-exception record is made if the event that would do so directly causes a VM exit.
  - If a machine-check exception causes a VM exit directly, this does not prevent machine-check MSRs from being updated. These are updated by the machine-check event itself and not the resulting machine-check exception.
  - If the logical processor is in an inactive state (see Section 24.4.2) and not executing instructions, some events may be blocked but others may return the logical processor to the active state. Unblocked events may cause VM exits.[2] If an unblocked event causes a VM exit directly, a return to the active state occurs only after the VM exit completes.[3] The VM exit generates any special bus cycle that is normally generated when the active state is entered from that activity state.

    MTF VM exits (see Section 25.5.2 and Section 26.6.8) are not blocked in the HLT activity state. If an MTF VM exit occurs in the HLT activity state, the logical processor returns to the active state only after the VM exit completes. MTF VM exits are blocked the shutdown state and the wait-for-SIPI state.

- If an event causes a VM exit indirectly, the event does update architectural state:
  - A debug exception updates DR6, DR7, and the IA32_DEBUGCTL MSR. No debug exceptions are considered pending.
  - A page fault updates CR2.
  - An NMI causes subsequent NMIs to be blocked before the VM exit commences.
  - An external interrupt acknowledges the interrupt controller and the interrupt is no longer pending.
  - If the logical processor had been in an inactive state, it enters the active state and, before the VM exit commences, generates any special bus cycle that is normally generated when the active state is entered from that activity state.
  - There is no blocking by STI or by MOV SS when the VM exit commences.
  - Processor state that is normally updated as part of delivery through the IDT (CS, RIP, SS, RSP, RFLAGS) is not modified. However, the incomplete delivery of the event may write to the stack.
  - The treatment of last-exception records is implementation dependent:
    - Some processors make a last-exception record when beginning the delivery of an event through the IDT (before it can encounter a nested exception). Such processors perform this update even if the event encounters a nested exception that causes a VM exit (including the case where nested exceptions lead to a triple fault).
    - Other processors delay making a last-exception record until event delivery has reached some event handler successfully (perhaps after one or more nested exceptions). Such processors do not update the last-exception record if a VM exit or triple fault occurs before an event handler is reached.
- If the "virtual NMIs" VM-execution control is 1, VM entry injects an NMI, and delivery of the NMI causes a nested exception, double fault, task switch, or APIC access that causes a VM exit, virtual-NMI blocking is in effect before the VM exit commences.

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.
2. If a VM exit takes the processor from an inactive state resulting from execution of a specific instruction (HLT or MWAIT), the value saved for RIP by that VM exit will reference the following instruction.
3. An exception is made if the logical processor had been inactive due to execution of MWAIT; in this case, it is considered to have become active before the VM exit.

- If a VM exit results from a fault, EPT violation, or EPT misconfiguration encountered during execution of IRET and the "NMI exiting" VM-execution control is 0, any blocking by NMI is cleared before the VM exit commences. However, the previous state of blocking by NMI may be recorded in the VM-exit interruption-information field; see Section 27.2.2.
- If a VM exit results from a fault, EPT violation, or EPT misconfiguration encountered during execution of IRET and the "virtual NMIs" VM-execution control is 1, virtual-NMI blocking is cleared before the VM exit commences. However, the previous state of virtual-NMI blocking may be recorded in the VM-exit interruption-information field; see Section 27.2.2.
- Suppose that a VM exit is caused directly by an x87 FPU Floating-Point Error (#MF) or by any of the following events if the event was unblocked due to (and given priority over) an x87 FPU Floating-Point Error: an INIT signal, an external interrupt, an NMI, an SMI; or a machine-check exception. In these cases, there is no blocking by STI or by MOV SS when the VM exit commences.
- Normally, a last-branch record may be made when an event is delivered through the IDT. However, if such an event results in a VM exit before delivery is complete, no last-branch record is made.
- If machine-check exception results in a VM exit, processor state is suspect and may result in suspect state being saved to the guest-state area. A VM monitor should consult the RIPV and EIPV bits in the IA32_MCG_STATUS MSR before resuming a guest that caused a VM exit resulting from a machine-check exception.
- If a VM exit results from a fault, APIC access (see Section 29.4), EPT violation, or EPT misconfiguration encountered while executing an instruction, data breakpoints due to that instruction may have been recognized and information about them may be saved in the pending debug exceptions field (see Section 27.3.4).
- The following VM exits are considered to happen after an instruction is executed:
  - VM exits resulting from debug traps (single-step, I/O breakpoints, and data breakpoints).
  - VM exits resulting from debug exceptions whose recognition was delayed by blocking by MOV SS.
  - VM exits resulting from some machine-check exceptions.
  - Trap-like VM exits due to execution of MOV to CR8 when the "CR8-load exiting" VM-execution control is 0 and the "use TPR shadow" VM-execution control is 1 (see Section 29.3). (Such VM exits can occur only from 64-bit mode and thus only on processors that support Intel 64 architecture.)
  - Trap-like VM exits due to execution of WRMSR when the "use MSR bitmaps" VM-execution control is 1; the value of ECX is in the range 800H–8FFH; and the bit corresponding to the ECX value in write bitmap for low MSRs is 0; and the "virtualize x2APIC mode" VM-execution control is 1. See Section 29.5.
  - VM exits caused by APIC-write emulation (see Section 29.4.3.2) that result from APIC accesses as part of instruction execution.

  For these VM exits, the instruction's modifications to architectural state complete before the VM exit occurs. Such modifications include those to the logical processor's interruptibility state (see Table 24-3). If there had been blocking by MOV SS, POP SS, or STI before the instruction executed, such blocking is no longer in effect.

## 27.2 RECORDING VM-EXIT INFORMATION AND UPDATING VM-ENTRY CONTROL FIELDS

VM exits begin by recording information about the nature of and reason for the VM exit in the VM-exit information fields. Section 27.2.1 to Section 27.2.4 detail the use of these fields.

In addition to updating the VM-exit information fields, the valid bit (bit 31) is cleared in the VM-entry interruption-information field. If bit 5 of the IA32_VMX_MISC MSR (index 485H) is read as 1 (see Appendix A.6), the value of IA32_EFER.LMA is stored into the "IA-32e mode guest" VM-entry control.[1]

1. Bit 5 of the IA32_VMX_MISC MSR is read as 1 on any logical processor that supports the 1-setting of the "unrestricted guest" VM-execution control.

### 27.2.1 Basic VM-Exit Information

Section 24.9.1 defines the basic VM-exit information fields. The following items detail their use.

- **Exit reason.**
  - Bits 15:0 of this field contain the basic exit reason. It is loaded with a number indicating the general cause of the VM exit. Appendix C lists the numbers used and their meaning.
  - The remainder of the field (bits 31:16) is cleared to 0 (certain SMM VM exits may set some of these bits; see Section 34.15.2.3).[1]
- **Exit qualification.** This field is saved for VM exits due to the following causes: debug exceptions; page-fault exceptions; start-up IPIs (SIPIs); system-management interrupts (SMIs) that arrive immediately after the retirement of I/O instructions; task switches; INVEPT; INVLPG; INVPCID; INVVPID; LGDT; LIDT; LLDT; LTR; SGDT; SIDT; SLDT; STR; VMCLEAR; VMPTRLD; VMPTRST; VMREAD; VMWRITE; VMXON; XRSTORS; XSAVES; control-register accesses; MOV DR; I/O instructions; MWAIT; accesses to the APIC-access page (see Section 29.4); EPT violations; EOI virtualization (Section 29.1.4); and APIC-write emulation (see Section 29.4.3.3). For all other VM exits, this field is cleared. The following items provide details:
  - For a debug exception, the exit qualification contains information about the debug exception. The information has the format given in Table 27-1.

**Table 27-1. Exit Qualification for Debug Exceptions**

| Bit Position(s) | Contents |
|---|---|
| 3:0 | B3 – B0. When set, each of these bits indicates that the corresponding breakpoint condition was met. Any of these bits may be set even if its corresponding enabling bit in DR7 is not set. |
| 12:4 | Reserved (cleared to 0). |
| 13 | BD. When set, this bit indicates that the cause of the debug exception is "debug register access detected." |
| 14 | BS. When set, this bit indicates that the cause of the debug exception is either the execution of a single instruction (if RFLAGS.TF = 1 and IA32_DEBUGCTL.BTF = 0) or a taken branch (if RFLAGS.TF = DEBUGCTL.BTF = 1). |
| 63:15 | Reserved (cleared to 0). Bits 63:32 exist only on processors that support Intel 64 architecture. |

  - For a page-fault exception, the exit qualification contains the linear address that caused the page fault. On processors that support Intel 64 architecture, bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
  - For a start-up IPI (SIPI), the exit qualification contains the SIPI vector information in bits 7:0. Bits 63:8 of the exit qualification are cleared to 0.
  - For a task switch, the exit qualification contains details about the task switch, encoded as shown in Table 27-2.
  - For INVLPG, the exit qualification contains the linear-address operand of the instruction.
    - On processors that support Intel 64 architecture, bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
    - If the INVLPG source operand specifies an unusable segment, the linear address specified in the exit qualification will match the linear address that the INVLPG would have used if no VM exit occurred. This address is not architecturally defined and may be implementation-specific.

1. Bit 13 of this field is set on certain VM-entry failures; see Section 26.7.

**Table 27-2. Exit Qualification for Task Switch**

| Bit Position(s) | Contents |
|---|---|
| 15:0 | Selector of task-state segment (TSS) to which the guest attempted to switch |
| 29:16 | Reserved (cleared to 0) |
| 31:30 | Source of task switch initiation:<br>0: CALL instruction<br>1: IRET instruction<br>2: JMP instruction<br>3: Task gate in IDT |
| 63:32 | Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture. |

— For INVEPT, INVPCID, INVVPID, LGDT, LIDT, LLDT, LTR, SGDT, SIDT, SLDT, STR, VMCLEAR, VMPTRLD, VMPTRST, VMREAD, VMWRITE, VMXON, XRSTORS, and XSAVES, the exit qualification receives the value of the instruction's displacement field, which is sign-extended to 64 bits if necessary (32 bits on processors that do not support Intel 64 architecture). If the instruction has no displacement (for example, has a register operand), zero is stored into the exit qualification.

  On processors that support Intel 64 architecture, an exception is made for RIP-relative addressing (used only in 64-bit mode). Such addressing causes an instruction to use an address that is the sum of the displacement field and the value of RIP that references the following instruction. In this case, the exit qualification is loaded with the sum of the displacement field and the appropriate RIP value.

  In all cases, bits of this field beyond the instruction's address size are undefined. For example, suppose that the address-size field in the VM-exit instruction-information field (see Section 24.9.4 and Section 27.2.4) reports an *n*-bit address size. Then bits 63:*n* (bits 31:*n* on processors that do not support Intel 64 architecture) of the instruction displacement are undefined.

— For a control-register access, the exit qualification contains information about the access and has the format given in Table 27-3.

— For MOV DR, the exit qualification contains information about the instruction and has the format given in Table 27-4.

— For an I/O instruction, the exit qualification contains information about the instruction and has the format given in Table 27-5.

— For MWAIT, the exit qualification contains a value that indicates whether address-range monitoring hardware was armed. The exit qualification is set either to 0 (if address-range monitoring hardware is not armed) or to 1 (if address-range monitoring hardware is armed).

— For an APIC-access VM exit resulting from a linear access or a guest-physical access to the APIC-access page (see Section 29.4), the exit qualification contains information about the access and has the format given in Table 27-6.[1]

  Such a VM exit that set bits 15:12 of the exit qualification to 0000b (data read during instruction execution) or 0001b (data write during instruction execution) set bit 12—which distinguishes data read from data write—to that which would have been stored in bit 1—W/R—of the page-fault error code had the access caused a page fault instead of an APIC-access VM exit. This implies the following:

  - For an APIC-access VM exit caused by the CLFLUSH instruction, the access type is "data read during instruction execution."
  - For an APIC-access VM exit caused by the ENTER instruction, the access type is "data write during instruction execution."

1. The exit qualification is undefined if the access was part of the logging of a branch record or a precise-event-based-sampling (PEBS) record to the DS save area. It is recommended that software configure the paging structures so that no address in the DS save area translates to an address on the APIC-access page.

**Table 27-3. Exit Qualification for Control-Register Accesses**

| Bit Positions | Contents |
|---|---|
| 3:0 | Number of control register (0 for CLTS and LMSW). Bit 3 is always 0 on processors that do not support Intel 64 architecture as they do not support CR8. |
| 5:4 | Access type:<br>0 = MOV to CR<br>1 = MOV from CR<br>2 = CLTS<br>3 = LMSW |
| 6 | LMSW operand type:<br>0 = register<br>1 = memory<br><br>For CLTS and MOV CR, cleared to 0 |
| 7 | Reserved (cleared to 0) |
| 11:8 | For MOV CR, the general-purpose register:<br>0 = RAX<br>1 = RCX<br>2 = RDX<br>3 = RBX<br>4 = RSP<br>5 = RBP<br>6 = RSI<br>7 = RDI<br>8–15 represent R8–R15, respectively (used only on processors that support Intel 64 architecture)<br><br>For CLTS and LMSW, cleared to 0 |
| 15:12 | Reserved (cleared to 0) |
| 31:16 | For LMSW, the LMSW source data<br>For CLTS and MOV CR, cleared to 0 |
| 63:32 | Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture. |

- For an APIC-access VM exit caused by the MASKMOVQ instruction or the MASKMOVDQU instruction, the access type is "data write during instruction execution."
- For an APIC-access VM exit caused by the MONITOR instruction, the access type is "data read during instruction execution."

Such a VM exit stores 1 for bit 31 for IDT-vectoring information field (see Section 27.2.3) if and only if it sets bits 15:12 of the exit qualification to 0011b (linear access during event delivery) or 1010b (guest-physical access during event delivery).

See Section 29.4.4 for further discussion of these instructions and APIC-access VM exits.

For APIC-access VM exits resulting from physical accesses to the APIC-access page (see Section 29.4.6), the exit qualification is undefined.

— For an EPT violation, the exit qualification contains information about the access causing the EPT violation and has the format given in Table 27-7.

An EPT violation that occurs during as a result of execution of a read-modify-write operation sets bit 1 (data write). Whether it also sets bit 0 (data read) is implementation-specific and, for a given implementation, may differ for different kinds of read-modify-write operations.

### Table 27-4. Exit Qualification for MOV DR

| Bit Position(s) | Contents |
|---|---|
| 2:0 | Number of debug register |
| 3 | Reserved (cleared to 0) |
| 4 | Direction of access (0 = MOV to DR; 1 = MOV from DR) |
| 7:5 | Reserved (cleared to 0) |
| 11:8 | General-purpose register:<br>0 = RAX<br>1 = RCX<br>2 = RDX<br>3 = RBX<br>4 = RSP<br>5 = RBP<br>6 = RSI<br>7 = RDI<br>8 –15 = R8 – R15, respectively |
| 63:12 | Reserved (cleared to 0) |

### Table 27-5. Exit Qualification for I/O Instructions

| Bit Position(s) | Contents |
|---|---|
| 2:0 | Size of access:<br>0 = 1-byte<br>1 = 2-byte<br>3 = 4-byte<br><br>Other values not used |
| 3 | Direction of the attempted access (0 = OUT, 1 = IN) |
| 4 | String instruction (0 = not string; 1 = string) |
| 5 | REP prefixed (0 = not REP; 1 = REP) |
| 6 | Operand encoding (0 = DX, 1 = immediate) |
| 15:7 | Reserved (cleared to 0) |
| 31:16 | Port number (as specified in DX or in an immediate operand) |
| 63:32 | Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture. |

Bit 12 is undefined in any of the following cases:

- If the "NMI exiting" VM-execution control is 1 and the "virtual NMIs" VM-execution control is 0.
- If the VM exit sets the valid bit in the IDT-vectoring information field (see Section 27.2.3).

Otherwise, bit 12 is defined as follows:

- If the "virtual NMIs" VM-execution control is 0, the EPT violation was caused by a memory access as part of execution of the IRET instruction, and blocking by NMI (see Table 24-3) was in effect before execution of IRET, bit 12 is set to 1.

**Table 27-6. Exit Qualification for APIC-Access VM Exits from Linear Accesses and Guest-Physical Accesses**

| Bit Position(s) | Contents |
|---|---|
| 11:0 | ▪ If the APIC-access VM exit is due to a linear access, the offset of access within the APIC page.<br>▪ Undefined if the APIC-access VM exit is due a guest-physical access |
| 15:12 | Access type:<br>0 = linear access for a data read during instruction execution<br>1 = linear access for a data write during instruction execution<br>2 = linear access for an instruction fetch<br>3 = linear access (read or write) during event delivery<br>10 = guest-physical access during event delivery<br>15 = guest-physical access for an instruction fetch or during instruction execution<br><br>Other values not used |
| 63:16 | Reserved (cleared to 0). Bits 63:32 exist only on processors that support Intel 64 architecture. |

  - If the "virtual NMIs" VM-execution control is 1,the EPT violation was caused by a memory access as part of execution of the IRET instruction, and virtual-NMI blocking was in effect before execution of IRET, bit 12 is set to 1.
  - For all other relevant VM exits, bit 12 is cleared to 0.

  — For VM exits caused as part of EOI virtualization (Section 29.1.4), bits 7:0 of the exit qualification are set to vector of the virtual interrupt that was dismissed by the EOI virtualization. Bits above bit 7 are cleared.

  — For APIC-write VM exits (Section 29.4.3.3), bits 11:0 of the exit qualification are set to the page offset of the write access that caused the VM exit.[1] Bits above bit 11 are cleared.

- **Guest-linear address.** For some VM exits, this field receives a linear address that pertains to the VM exit. The field is set for different VM exits as follows:

  — VM exits due to attempts to execute LMSW with a memory operand. In these cases, this field receives the linear address of that operand. Bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.

  — VM exits due to attempts to execute INS or OUTS for which the relevant segment is usable (if the relevant segment is not usable, the value is undefined). (ES is always the relevant segment for INS; for OUTS, the relevant segment is DS unless overridden by an instruction prefix.) The linear address is the base address of relevant segment plus (E)DI (for INS) or (E)SI (for OUTS). Bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.

  — VM exits due to EPT violations that set bit 7 of the exit qualification (see Table 27-7; these are all EPT violations except those resulting from an attempt to load the PDPTEs as of execution of the MOV CR instruction). The linear address may translate to the guest-physical address whose access caused the EPT violation. Alternatively, translation of the linear address may reference a paging-structure entry whose access caused the EPT violation. Bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.

  — For all other VM exits, the field is undefined.

- **Guest-physical address.** For a VM exit due to an EPT violation or an EPT misconfiguration, this field receives the guest-physical address that caused the EPT violation or EPT misconfiguration. For all other VM exits, the field is undefined.

1. Execution of WRMSR with ECX = 83FH (self-IPI MSR) can lead to an APIC-write VM exit; the exit qualification for such an APIC-write VM exit is 3F0H.

Table 27-7. Exit Qualification for EPT Violations

| Bit Position(s) | Contents |
|---|---|
| 0 | Set if the access causing the EPT violation was a data read.[1] |
| 1 | Set if the access causing the EPT violation was a data write.[1] |
| 2 | Set if the access causing the EPT violation was an instruction fetch. |
| 3 | The logical-AND of bit 0 in the EPT paging-structure entries used to translate the guest-physical address of the access causing the EPT violation (indicates that the guest-physical address was readable).[2] |
| 4 | The logical-AND of bit 1 in the EPT paging-structure entries used to translate the guest-physical address of the access causing the EPT violation (indicates that the guest-physical address was writeable). |
| 5 | The logical-AND of bit 2 in the EPT paging-structure entries used to translate the guest-physical address of the access causing the EPT violation (indicates that the guest-physical address was executable). |
| 6 | Reserved (cleared to 0). |
| 7 | Set if the guest linear-address field is valid.<br>The guest linear-address field is valid for all EPT violations except those resulting from an attempt to load the guest PDPTEs as part of the execution of the MOV CR instruction. |
| 8 | If bit 7 is 1:<br>▪ Set if the access causing the EPT violation is to a guest-physical address that is the translation of a linear address.<br>▪ Clear if the access causing the EPT violation is to a paging-structure entry as part of a page walk or the update of an accessed or dirty bit.<br>Reserved if bit 7 is 0 (cleared to 0). |
| 11:9 | Reserved (cleared to 0). |
| 12 | NMI unblocking due to IRET |
| 63:13 | Reserved (cleared to 0). |

NOTES:

1. If accessed and dirty flags for EPT are enabled, processor accesses to guest paging-structure entries are treated as writes with regard to EPT violations (see Section 28.2.3.2). If such an access causes an EPT violation, the processor sets both bit 0 and bit 1 of the exit qualification.
2. Bits 5:3 are cleared to 0 if any of EPT paging-structure entries used to translate the guest-physical address of the access causing the EPT violation is not present (see Section 28.2.2).

## 27.2.2 Information for VM Exits Due to Vectored Events

Section 24.9.2 defines fields containing information for VM exits due to the following events: exceptions (including those generated by the instructions INT3, INTO, BOUND, and UD2); external interrupts that occur while the "acknowledge interrupt on exit" VM-exit control is 1; and non-maskable interrupts (NMIs). Such VM exits include those that occur on an attempt at a task switch that causes an exception before generating the VM exit due to the task switch that causes the VM exit.

The following items detail the use of these fields:

- **VM-exit interruption information** (format given in Table 24-15). The following items detail how this field is established for VM exits due to these events:
  - For an exception, bits 7:0 receive the exception vector (at most 31). For an NMI, bits 7:0 are set to 2. For an external interrupt, bits 7:0 receive the vector.
  - Bits 10:8 are set to 0 (external interrupt), 2 (non-maskable interrupt), 3 (hardware exception), or 6 (software exception). Hardware exceptions comprise all exceptions except breakpoint exceptions (#BP;

generated by INT3) and overflow exceptions (#OF; generated by INTO); these are software exceptions. BOUND-range exceeded exceptions (#BR; generated by BOUND) and invalid opcode exceptions (#UD) generated by UD2 are hardware exceptions.

— Bit 11 is set to 1 if the VM exit is caused by a hardware exception that would have delivered an error code on the stack. This bit is always 0 if the VM exit occurred while the logical processor was in real-address mode (CR0.PE=0).[1] If bit 11 is set to 1, the error code is placed in the VM-exit interruption error code (see below).

— Bit 12 is undefined in any of the following cases:

- If the "NMI exiting" VM-execution control is 1 and the "virtual NMIs" VM-execution control is 0.
- If the VM exit sets the valid bit in the IDT-vectoring information field (see Section 27.2.3).
- If the VM exit is due to a double fault (the interruption type is hardware exception and the vector is 8).

Otherwise, bit 12 is defined as follows:

- If the "virtual NMIs" VM-execution control is 0, the VM exit is due to a fault on the IRET instruction (other than a debug exception for an instruction breakpoint), and blocking by NMI (see Table 24-3) was in effect before execution of IRET, bit 12 is set to 1.
- If the "virtual NMIs" VM-execution control is 1, the VM exit is due to a fault on the IRET instruction (other than a debug exception for an instruction breakpoint), and virtual-NMI blocking was in effect before execution of IRET, bit 12 is set to 1.
- For all other relevant VM exits, bit 12 is cleared to 0.[2]

— Bits 30:13 are always set to 0.

— Bit 31 is always set to 1.

For other VM exits (including those due to external interrupts when the "acknowledge interrupt on exit" VM-exit control is 0), the field is marked invalid (by clearing bit 31) and the remainder of the field is undefined.

- VM-exit interruption error code.

— For VM exits that set both bit 31 (valid) and bit 11 (error code valid) in the VM-exit interruption-information field, this field receives the error code that would have been pushed on the stack had the event causing the VM exit been delivered normally through the IDT. The EXT bit is set in this field exactly when it would be set normally. For exceptions that occur during the delivery of double fault (if the IDT-vectoring information field indicates a double fault), the EXT bit is set to 1, assuming that (1) that the exception would produce an error code normally (if not incident to double-fault delivery) and (2) that the error code uses the EXT bit (not for page faults, which use a different format).

— For other VM exits, the value of this field is undefined.

### 27.2.3 Information for VM Exits During Event Delivery

Section 24.9.3 defined fields containing information for VM exits that occur while delivering an event through the IDT and as a result of any of the following cases:[3]

- A fault occurs during event delivery and causes a VM exit (because the bit associated with the fault is set to 1 in the exception bitmap).
- A task switch is invoked through a task gate in the IDT. The VM exit occurs due to the task switch only after the initial checks of the task switch pass (see Section 25.4.2).

---

1. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PE must be 1 in VMX operation, a logical processor cannot be in real-address mode unless the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
2. The conditions imply that, if the "NMI exiting" VM-execution control is 0 or the "virtual NMIs" VM-execution control is 1, bit 12 is always cleared to 0 by VM exits due to debug exceptions.
3. This includes the case in which a VM exit occurs while delivering a software interrupt (INT *n*) through the 16-bit IVT (interrupt vector table) that is used in virtual-8086 mode with virtual-machine extensions (if RFLAGS.VM = CR4.VME = 1).

- Event delivery causes an APIC-access VM exit (see Section 29.4).
- An EPT violation or EPT misconfiguration that occurs during event delivery.

These fields are used for VM exits that occur during delivery of events injected as part of VM entry (see Section 26.5.1.2).

A VM exit is not considered to occur during event delivery in any of the following circumstances:

- The original event causes the VM exit directly (for example, because the original event is a non-maskable interrupt (NMI) and the "NMI exiting" VM-execution control is 1).
- The original event results in a double-fault exception that causes the VM exit directly.
- The VM exit occurred as a result of fetching the first instruction of the handler invoked by the event delivery.
- The VM exit is caused by a triple fault.

The following items detail the use of these fields:

- IDT-vectoring information (format given in Table 24-16). The following items detail how this field is established for VM exits that occur during event delivery:
  - If the VM exit occurred during delivery of an exception, bits 7:0 receive the exception vector (at most 31). If the VM exit occurred during delivery of an NMI, bits 7:0 are set to 2. If the VM exit occurred during delivery of an external interrupt, bits 7:0 receive the vector.
  - Bits 10:8 are set to indicate the type of event that was being delivered when the VM exit occurred: 0 (external interrupt), 2 (non-maskable interrupt), 3 (hardware exception), 4 (software interrupt), 5 (privileged software interrupt), or 6 (software exception).

    Hardware exceptions comprise all exceptions except breakpoint exceptions (#BP; generated by INT3) and overflow exceptions (#OF; generated by INTO); these are software exceptions. BOUND-range exceeded exceptions (#BR; generated by BOUND) and invalid opcode exceptions (#UD) generated by UD2 are hardware exceptions.

    Bits 10:8 may indicate privileged software interrupt if such an event was injected as part of VM entry.
  - Bit 11 is set to 1 if the VM exit occurred during delivery of a hardware exception that would have delivered an error code on the stack. This bit is always 0 if the VM exit occurred while the logical processor was in real-address mode (CR0.PE=0).[1] If bit 11 is set to 1, the error code is placed in the IDT-vectoring error code (see below).
  - Bit 12 is undefined.
  - Bits 30:13 are always set to 0.
  - Bit 31 is always set to 1.

  For other VM exits, the field is marked invalid (by clearing bit 31) and the remainder of the field is undefined.
- IDT-vectoring error code.
  - For VM exits that set both bit 31 (valid) and bit 11 (error code valid) in the IDT-vectoring information field, this field receives the error code that would have been pushed on the stack by the event that was being delivered through the IDT at the time of the VM exit. The EXT bit is set in this field when it would be set normally.
  - For other VM exits, the value of this field is undefined.

### 27.2.4 Information for VM Exits Due to Instruction Execution

Section 24.9.4 defined fields containing information for VM exits that occur due to instruction execution. (The VM-exit instruction length is also used for VM exits that occur during the delivery of a software interrupt or software exception.) The following items detail their use.

1. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PE must be 1 in VMX operation, a logical processor cannot be in real-address mode unless the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

- **VM-exit instruction length.** This field is used in the following cases:
  - For fault-like VM exits due to attempts to execute one of the following instructions that cause VM exits unconditionally (see Section 25.1.2) or based on the settings of VM-execution controls (see Section 25.1.3): CLTS, CPUID, GETSEC, HLT, IN, INS, INVD, INVEPT, INVLPG, INVPCID, INVVPID, LGDT, LIDT, LLDT, LMSW, LTR, MONITOR, MOV CR, MOV DR, MWAIT, OUT, OUTS, PAUSE, RDMSR, RDPMC, RDRAND, RDSEED, RDTSC, RDTSCP, RSM, SGDT, SIDT, SLDT, STR, VMCALL, VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMREAD, VMRESUME, VMWRITE, VMXOFF, VMXON, WBINVD, WRMSR, XRSTORS, XSETBV, and XSAVES.[1]
  - For VM exits due to software exceptions (those generated by executions of INT3 or INTO).
  - For VM exits due to faults encountered during delivery of a software interrupt, privileged software exception, or software exception.
  - For VM exits due to attempts to effect a task switch via instruction execution. These are VM exits that produce an exit reason indicating task switch and either of the following:
    - An exit qualification indicating execution of CALL, IRET, or JMP instruction.
    - An exit qualification indicating a task gate in the IDT and an IDT-vectoring information field indicating that the task gate was encountered during delivery of a software interrupt, privileged software exception, or software exception.
  - For APIC-access VM exits resulting from accesses (see Section 29.4) during delivery of a software interrupt, privileged software exception, or software exception.[2]
  - For VM exits due executions of VMFUNC that fail because one of the following is true:
    - EAX indicates a VM function that is not enabled (the bit at position EAX is 0 in the VM-function controls; see Section 25.5.5.2).
    - EAX = 0 and either ECX ≥ 512 or the value of ECX selects an invalid tentative EPTP value (see Section 25.5.5.3).

  In all the above cases, this field receives the length in bytes (1–15) of the instruction (including any instruction prefixes) whose execution led to the VM exit (see the next paragraph for one exception).

  The cases of VM exits encountered during delivery of a software interrupt, privileged software exception, or software exception include those encountered during delivery of events injected as part of VM entry (see Section 26.5.1.2). If the original event was injected as part of VM entry, this field receives the value of the VM-entry instruction length.

  All VM exits other than those listed in the above items leave this field undefined.
- **VM-exit instruction information**. For VM exits due to attempts to execute INS, INVEPT, INVPCID, INVVPID, LIDT, LGDT, LLDT, LTR, OUTS, RDRAND, RDSEED, SIDT, SGDT, SLDT, STR, VMCLEAR, VMPTRLD, VMPTRST, VMREAD, VMWRITE, VMXON, XRSTORS, or XSAVES, this field receives information about the instruction that caused the VM exit. The format of the field depends on the identity of the instruction causing the VM exit:
  - For VM exits due to attempts to execute INS or OUTS, the field has the format is given in Table 27-8.[3]
  - For VM exits due to attempts to execute INVEPT, INVPCID, or INVVPID, the field has the format is given in Table 27-9.
  - For VM exits due to attempts to execute LIDT, LGDT, SIDT, or SGDT, the field has the format is given in Table 27-10.
  - For VM exits due to attempts to execute LLDT, LTR, SLDT, or STR, the field has the format is given in Table 27-11.

---

1. This item applies only to fault-like VM exits. It does not apply to trap-like VM exits following executions of the MOV to CR8 instruction when the "use TPR shadow" VM-execution control is 1 or to those following executions of the WRMSR instruction when the "virtualize x2APIC mode" VM-execution control is 1.
2. The VM-exit instruction-length field is not defined following APIC-access VM exits resulting from physical accesses (see Section 29.4.6) even if encountered during delivery of a software interrupt, privileged software exception, or software exception.
3. The format of the field was undefined for these VM exits on the first processors to support the virtual-machine extensions. Software can determine whether the format specified in Table 27-8 is used by consulting the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1).

**Table 27-8. Format of the VM-Exit Instruction-Information Field as Used for INS and OUTS**

| Bit Position(s) | Content |
|---|---|
| 6:0 | Undefined. |
| 9:7 | Address size:<br>0: 16-bit<br>1: 32-bit<br>2: 64-bit (used only on processors that support Intel 64 architecture)<br>Other values not used. |
| 14:10 | Undefined. |
| 17:15 | Segment register:<br>0: ES<br>1: CS<br>2: SS<br>3: DS<br>4: FS<br>5: GS<br>Other values not used. Undefined for VM exits due to execution of INS. |
| 31:18 | Undefined. |

  - For VM exits due to attempts to execute RDRAND or RDSEED, the field has the format is given in Table 27-12.
  - For VM exits due to attempts to execute VMCLEAR, VMPTRLD, VMPTRST, VMXON, XRSTORS, or XSAVES, the field has the format is given in Table 27-13.
  - For VM exits due to attempts to execute VMREAD or VMWRITE, the field has the format is given in Table 27-14.

  For all other VM exits, the field is undefined.

- **I/O RCX, I/O RSI, I/O RDI, I/O RIP**. These fields are undefined except for SMM VM exits due to system-management interrupts (SMIs) that arrive immediately after retirement of I/O instructions. See Section 34.15.2.3.

## 27.3 SAVING GUEST STATE

Each field in the guest-state area of the VMCS (see Section 24.4) is written with the corresponding component of processor state. On processors that support Intel 64 architecture, the full values of each natural-width field (see Section 24.11.2) is saved regardless of the mode of the logical processor before and after the VM exit.

In general, the state saved is that which was in the logical processor at the time the VM exit commences. See Section 27.1 for a discussion of which architectural updates occur at that time.

Section 27.3.1 through Section 27.3.4 provide details for how certain components of processor state are saved. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the guest-state area.

### 27.3.1 Saving Control Registers, Debug Registers, and MSRs

Contents of certain control registers, debug registers, and MSRs is saved as follows:

- The contents of CR0, CR3, CR4, and the IA32_SYSENTER_CS, IA32_SYSENTER_ESP, and IA32_SYSENTER_EIP MSRs are saved into the corresponding fields. Bits 63:32 of the IA32_SYSENTER_CS MSR are not saved. On processors that do not support Intel 64 architecture, bits 63:32 of the IA32_SYSENTER_ESP and IA32_SYSENTER_EIP MSRs are not saved.
- If the "save debug controls" VM-exit control is 1, the contents of DR7 and the IA32_DEBUGCTL MSR are saved into the corresponding fields. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus always saved data into these fields.
- If the "save IA32_PAT" VM-exit control is 1, the contents of the IA32_PAT MSR are saved into the corresponding field.
- If the "save IA32_EFER" VM-exit control is 1, the contents of the IA32_EFER MSR are saved into the corresponding field.
- The value of the SMBASE field is undefined after all VM exits except SMM VM exits. See Section 34.15.2.

### 27.3.2 Saving Segment Registers and Descriptor-Table Registers

For each segment register (CS, SS, DS, ES, FS, GS, LDTR, or TR), the values saved for the base-address, segment-limit, and access rights are based on whether the register was unusable (see Section 24.4.1) before the VM exit:

- If the register was unusable, the values saved into the following fields are undefined: (1) base address; (2) segment limit; and (3) bits 7:0 and bits 15:12 in the access-rights field. The following exceptions apply:
  - CS.
    - The base-address and segment-limit fields are saved.
    - The L, D, and G bits are saved in the access-rights field.
  - SS.
    - DPL is saved in the access-rights field.
    - On processors that support Intel 64 architecture, bits 63:32 of the value saved for the base address are always zero.
  - DS and ES. On processors that support Intel 64 architecture, bits 63:32 of the values saved for the base addresses are always zero.
  - FS and GS. The base-address field is saved.
  - LDTR. The value saved for the base address is always canonical.
- If the register was not unusable, the values saved into the following fields are those which were in the register before the VM exit: (1) base address; (2) segment limit; and (3) bits 7:0 and bits 15:12 in access rights.
- Bits 31:17 and 11:8 in the access-rights field are always cleared. Bit 16 is set to 1 if and only if the segment is unusable.

The contents of the GDTR and IDTR registers are saved into the corresponding base-address and limit fields.

### 27.3.3 Saving RIP, RSP, and RFLAGS

The contents of the RIP, RSP, and RFLAGS registers are saved as follows:

- The value saved in the RIP field is determined by the nature and cause of the VM exit:
  - If the VM exit occurs due to by an attempt to execute an instruction that causes VM exits unconditionally or that has been configured to cause a VM exit via the VM-execution controls, the value saved references that instruction.
  - If the VM exit is caused by an occurrence of an INIT signal, a start-up IPI (SIPI), or system-management interrupt (SMI), the value saved is that which was in RIP before the event occurred.
  - If the VM exit occurs due to the 1-setting of either the "interrupt-window exiting" VM-execution control or the "NMI-window exiting" VM-execution control, the value saved is that which would be in the register had the VM exit not occurred.
  - If the VM exit is due to an external interrupt, non-maskable interrupt (NMI), or hardware exception (as defined in Section 27.2.2), the value saved is the return pointer that would have been saved (either on the stack had the event been delivered through a trap or interrupt gate,[1] or into the old task-state segment had the event been delivered through a task gate).
  - If the VM exit is due to a triple fault, the value saved is the return pointer that would have been saved (either on the stack had the event been delivered through a trap or interrupt gate, or into the old task-state segment had the event been delivered through a task gate) had delivery of the double fault not encountered the nested exception that caused the triple fault.
  - If the VM exit is due to a software exception (due to an execution of INT3 or INTO), the value saved references the INT3 or INTO instruction that caused that exception.

1. The reference here is to the full value of RIP before any truncation that would occur had the stack width been only 32 bits or 16 bits.

  - Suppose that the VM exit is due to a task switch that was caused by execution of CALL, IRET, or JMP or by execution of a software interrupt (INT *n*) or software exception (due to execution of INT3 or INTO) that encountered a task gate in the IDT. The value saved references the instruction that caused the task switch (CALL, IRET, JMP, INT *n*, INT3, or INTO).
  - Suppose that the VM exit is due to a task switch that was caused by a task gate in the IDT that was encountered for any reason except the direct access by a software interrupt or software exception. The value saved is that which would have been saved in the old task-state segment had the task switch completed normally.
  - If the VM exit is due to an execution of MOV to CR8 or WRMSR that reduced the value of bits 7:4 of VTPR (see Section 29.1.1) below that of TPR threshold VM-execution control field (see Section 29.1.2), the value saved references the instruction following the MOV to CR8 or WRMSR.
  - If the VM exit was caused by APIC-write emulation (see Section 29.4.3.2) that results from an APIC access as part of instruction execution, the value saved references the instruction following the one whose execution caused the APIC-write emulation.
- The contents of the RSP register are saved into the RSP field.
- With the exception of the resume flag (RF; bit 16), the contents of the RFLAGS register is saved into the RFLAGS field. RFLAGS.RF is saved as follows:
  - If the VM exit is caused directly by an event that would normally be delivered through the IDT, the value saved is that which would appear in the saved RFLAGS image (either that which would be saved on the stack had the event been delivered through a trap or interrupt gate[1] or into the old task-state segment had the event been delivered through a task gate) had the event been delivered through the IDT. See below for VM exits due to task switches caused by task gates in the IDT.
  - If the VM exit is caused by a triple fault, the value saved is that which the logical processor would have in RF in the RFLAGS register had the triple fault taken the logical processor to the shutdown state.
  - If the VM exit is caused by a task switch (including one caused by a task gate in the IDT), the value saved is that which would have been saved in the RFLAGS image in the old task-state segment (TSS) had the task switch completed normally without exception.
  - If the VM exit is caused by an attempt to execute an instruction that unconditionally causes VM exits or one that was configured to do with a VM-execution control, the value saved is 0.[2]
  - For APIC-access VM exits and for VM exits caused by EPT violations and EPT misconfigurations, the value saved depends on whether the VM exit occurred during delivery of an event through the IDT:
    - If the VM exit stored 0 for bit 31 for IDT-vectoring information field (because the VM exit did not occur during delivery of an event through the IDT; see Section 27.2.3), the value saved is 1.
    - If the VM exit stored 1 for bit 31 for IDT-vectoring information field (because the VM exit did occur during delivery of an event through the IDT), the value saved is the value that would have appeared in the saved RFLAGS image had the event been delivered through the IDT (see above).
  - For all other VM exits, the value saved is the value RFLAGS.RF had before the VM exit occurred.

### 27.3.4 Saving Non-Register State

Information corresponding to guest non-register state is saved as follows:

1. The reference here is to the full value of RFLAGS before any truncation that would occur had the stack width been only 32 bits or 16 bits.
2. This is true even if RFLAGS.RF was 1 before the instruction was executed. If, in response to such a VM exit, a VM monitor re-enters the guest to re-execute the instruction that caused the VM exit (for example, after clearing the VM-execution control that caused the VM exit), the instruction may encounter a code breakpoint that has already been processed. A VM monitor can avoid this by setting the guest value of RFLAGS.RF to 1 before resuming guest software.

- The activity-state field is saved with the logical processor's activity state before the VM exit.[1] See Section 27.1 for details of how events leading to a VM exit may affect the activity state.
- The interruptibility-state field is saved to reflect the logical processor's interruptibility before the VM exit. See Section 27.1 for details of how events leading to a VM exit may affect this state. VM exits that end outside system-management mode (SMM) save bit 2 (blocking by SMI) as 0 regardless of the state of such blocking before the VM exit.

  Bit 3 (blocking by NMI) is treated specially if the "virtual NMIs" VM-execution control is 1. In this case, the value saved for this field does not indicate the blocking of NMIs but rather the state of virtual-NMI blocking.
- The pending debug exceptions field is saved as clear for all VM exits except the following:
  - A VM exit caused by an INIT signal, a machine-check exception, or a system-management interrupt (SMI).
  - A VM exit with basic exit reason "TPR below threshold",[2] "virtualized EOI", "APIC write", or "monitor trap flag."
  - VM exits that are not caused by debug exceptions and that occur while there is MOV-SS blocking of debug exceptions.

  For VM exits that do not clear the field, the value saved is determined as follows:
  - Each of bits 3:0 may be set if it corresponds to a matched breakpoint. This may be true even if the corresponding breakpoint is not enabled in DR7.
  - Suppose that a VM exit is due to an INIT signal, a machine-check exception, or an SMI; or that a VM exit has basic exit reason "TPR below threshold" or "monitor trap flag." In this case, the value saved sets bits corresponding to the causes of any debug exceptions that were pending at the time of the VM exit.

    If the VM exit occurs immediately after VM entry, the value saved may match that which was loaded on VM entry (see Section 26.6.3). Otherwise, the following items apply:
    - Bit 12 (enabled breakpoint) is set to 1 if there was at least one matched data or I/O breakpoint that was enabled in DR7. Bit 12 is also set if it had been set on VM entry, causing there to be valid pending debug exceptions (see Section 26.6.3) and the VM exit occurred before those exceptions were either delivered or lost. In other cases, bit 12 is cleared to 0.
    - Bit 14 (BS) is set if RFLAGS.TF = 1 in either of the following cases:
      - IA32_DEBUGCTL.BTF = 0 and the cause of a pending debug exception was the execution of a single instruction.
      - IA32_DEBUGCTL.BTF = 1 and the cause of a pending debug exception was a taken branch.
  - Suppose that a VM exit is due to another reason (but not a debug exception) and occurs while there is MOV-SS blocking of debug exceptions. In this case, the value saved sets bits corresponding to the causes of any debug exceptions that were pending at the time of the VM exit. If the VM exit occurs immediately after VM entry (no instructions were executed in VMX non-root operation), the value saved may match that which was loaded on VM entry (see Section 26.6.3). Otherwise, the following items apply:
    - Bit 12 (enabled breakpoint) is set to 1 if there was at least one matched data or I/O breakpoint that was enabled in DR7. Bit 12 is also set if it had been set on VM entry, causing there to be valid pending debug exceptions (see Section 26.6.3) and the VM exit occurred before those exceptions were either delivered or lost. In other cases, bit 12 is cleared to 0.
    - The setting of bit 14 (BS) is implementation-specific. However, it is not set if RFLAGS.TF = 0 or IA32_DEBUGCTL.BTF = 1.
  - The reserved bits in the field are cleared.
- If the "save VMX-preemption timer value" VM-exit control is 1, the value of timer is saved into the VMX-preemption timer-value field. This is the value loaded from this field on VM entry as subsequently decremented (see Section 25.5.1). VM exits due to timer expiration save the value 0. Other VM exits may also save the value

1. If this activity state was an inactive state resulting from execution of a specific instruction (HLT or MWAIT), the value saved for RIP by that VM exit will reference the following instruction.
2. This item includes VM exits that occur as a result of certain VM entries (Section 26.6.7).

0 if the timer expired during VM exit. (If the "save VMX-preemption timer value" VM-exit control is 0, VM exit does not modify the value of the VMX-preemption timer-value field.)

- If the logical processor supports the 1-setting of the "enable EPT" VM-execution control, values are saved into the four (4) PDPTE fields as follows:
  - If the "enable EPT" VM-execution control is 1 and the logical processor was using PAE paging at the time of the VM exit, the PDPTE values currently in use are saved:[1]
    - The values saved into bits 11:9 of each of the fields is undefined.
    - If the value saved into one of the fields has bit 0 (present) clear, the value saved into bits 63:1 of that field is undefined. That value need not correspond to the value that was loaded by VM entry or to any value that might have been loaded in VMX non-root operation.
    - If the value saved into one of the fields has bit 0 (present) set, the value saved into bits 63:12 of the field is a guest-physical address.
  - If the "enable EPT" VM-execution control is 0 or the logical processor was not using PAE paging at the time of the VM exit, the values saved are undefined.

## 27.4 SAVING MSRS

After processor state is saved to the guest-state area, values of MSRs may be stored into the VM-exit MSR-store area (see Section 24.7.2). Specifically each entry in that area (up to the number specified in the VM-exit MSR-store count) is processed in order by storing the value of the MSR indexed by bits 31:0 (as they would be read by RDMSR) into bits 127:64. Processing of an entry fails in either of the following cases:

- The value of bits 31:8 is 000008H, meaning that the indexed MSR is one that allows access to an APIC register when the local APIC is in x2APIC mode.
- The value of bits 31:0 indicates an MSR that can be read only in system-management mode (SMM) and the VM exit will not end in SMM. (IA32_SMBASE is an MSR that can be read only in SMM.)
- The value of bits 31:0 indicates an MSR that cannot be saved on VM exits for model-specific reasons. A processor may prevent certain MSRs (based on the value of bits 31:0) from being stored on VM exits, even if they can normally be read by RDMSR. Such model-specific behavior is documented in Chapter 35.
- Bits 63:32 of the entry are not all 0.
- An attempt to read the MSR indexed by bits 31:0 would cause a general-protection exception if executed via RDMSR with CPL = 0.

A VMX abort occurs if processing fails for any entry. See Section 27.7.

## 27.5 LOADING HOST STATE

Processor state is updated on VM exits in the following ways:

- Some state is loaded from or otherwise determined by the contents of the host-state area.
- Some state is determined by VM-exit controls.
- Some state is established in the same way on every VM exit.
- The page-directory pointers are loaded based on the values of certain control registers.

This loading may be performed in any order.

On processors that support Intel 64 architecture, the full values of each 64-bit field loaded (for example, the base address for GDTR) is loaded regardless of the mode of the logical processor before and after the VM exit.

---

1. A logical processor uses PAE paging if CR0.PG = 1, CR4.PAE = 1 and IA32_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*. "Enable EPT" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM exit functions as if the "enable EPT" VM-execution control were 0. See Section 24.6.2.

The loading of host state is detailed in Section 27.5.1 to Section 27.5.5. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the host-state area.

A logical processor is in IA-32e mode after a VM exit only if the "host address-space size" VM-exit control is 1. If the logical processor was in IA-32e mode before the VM exit and this control is 0, a VMX abort occurs. See Section 27.7.

In addition to loading host state, VM exits clear address-range monitoring (Section 27.5.6).

After the state loading described in this section, VM exits may load MSRs from the VM-exit MSR-load area (see Section 27.6). This loading occurs only after the state loading described in this section.

### 27.5.1 Loading Host Control Registers, Debug Registers, MSRs

VM exits load new values for controls registers, debug registers, and some MSRs:

- CR0, CR3, and CR4 are loaded from the CR0 field, the CR3 field, and the CR4 field, respectively, with the following exceptions:
  - The following bits are not modified:
    - For CR0, ET, CD, NW; bits 63:32 (on processors that support Intel 64 architecture), 28:19, 17, and 15:6; and any bits that are fixed in VMX operation (see Section 23.8).[1]
    - For CR3, bits 63:52 and bits in the range 51:32 beyond the processor's physical-address width (they are cleared to 0).[2] (This item applies only to processors that support Intel 64 architecture.)
    - For CR4, any bits that are fixed in VMX operation (see Section 23.8).
  - CR4.PAE is set to 1 if the "host address-space size" VM-exit control is 1.
  - CR4.PCIDE is set to 0 if the "host address-space size" VM-exit control is 0.
- DR7 is set to 400H.
- The following MSRs are established as follows:
  - The IA32_DEBUGCTL MSR is cleared to 00000000_00000000H.
  - The IA32_SYSENTER_CS MSR is loaded from the IA32_SYSENTER_CS field. Since that field has only 32 bits, bits 63:32 of the MSR are cleared to 0.
  - IA32_SYSENTER_ESP MSR and IA32_SYSENTER_EIP MSR are loaded from the IA32_SYSENTER_ESP field and the IA32_SYSENTER_EIP field, respectively.

    If the processor does not support the Intel 64 architecture, these fields have only 32 bits; bits 63:32 of the MSRs are cleared to 0.

    If the processor does support the Intel 64 architecture and the processor supports N < 64 linear-address bits, each of bits 63:N is set to the value of bit N–1.[3]
  - The following steps are performed on processors that support Intel 64 architecture:
    - The MSRs FS.base and GS.base are loaded from the base-address fields for FS and GS, respectively (see Section 27.5.2).
    - The LMA and LME bits in the IA32_EFER MSR are each loaded with the setting of the "host address-space size" VM-exit control.
  - If the "load IA32_PERF_GLOBAL_CTRL" VM-exit control is 1, the IA32_PERF_GLOBAL_CTRL MSR is loaded from the IA32_PERF_GLOBAL_CTRL field. Bits that are reserved in that MSR are maintained with their reserved values.

1. Bits 28:19, 17, and 15:6 of CR0 and CR0.ET are unchanged by executions of MOV to CR0. CR0.ET is always 1 and the other bits are always 0.
2. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
3. Software can determine the number N by executing CPUID with 80000008H in EAX. The number of linear-address bits supported is returned in bits 15:8 of EAX.

— If the "load IA32_PAT" VM-exit control is 1, the IA32_PAT MSR is loaded from the IA32_PAT field. Bits that are reserved in that MSR are maintained with their reserved values.

— If the "load IA32_EFER" VM-exit control is 1, the IA32_EFER MSR is loaded from the IA32_EFER field. Bits that are reserved in that MSR are maintained with their reserved values.

With the exception of FS.base and GS.base, any of these MSRs is subsequently overwritten if it appears in the VM-exit MSR-load area. See Section 27.6.

### 27.5.2 Loading Host Segment and Descriptor-Table Registers

Each of the registers CS, SS, DS, ES, FS, GS, and TR is loaded as follows (see below for the treatment of LDTR):

- The selector is loaded from the selector field. The segment is unusable if its selector is loaded with zero. The checks specified Section 26.3.1.2 limit the selector values that may be loaded. In particular, CS and TR are never loaded with zero and are thus never unusable. SS can be loaded with zero only on processors that support Intel 64 architecture and only if the VM exit is to 64-bit mode (64-bit mode allows use of segments marked unusable).
- The base address is set as follows:
  — CS. Cleared to zero.
  — SS, DS, and ES. Undefined if the segment is unusable; otherwise, cleared to zero.
  — FS and GS. Undefined (but, on processors that support Intel 64 architecture, canonical) if the segment is unusable and the VM exit is not to 64-bit mode; otherwise, loaded from the base-address field.

    If the processor supports the Intel 64 architecture and the processor supports N < 64 linear-address bits, each of bits 63:N is set to the value of bit N–1.[1] The values loaded for base addresses for FS and GS are also manifest in the FS.base and GS.base MSRs.
  — TR. Loaded from the host-state area. If the processor supports the Intel 64 architecture and the processor supports N < 64 linear-address bits, each of bits 63:N is set to the value of bit N–1.
- The segment limit is set as follows:
  — CS. Set to FFFFFFFFH (corresponding to a descriptor limit of FFFFFH and a G-bit setting of 1).
  — SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to FFFFFFFFH.
  — TR. Set to 00000067H.
- The type field and S bit are set as follows:
  — CS. Type set to 11 and S set to 1 (execute/read, accessed, non-conforming code segment).
  — SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, type set to 3 and S set to 1 (read/write, accessed, expand-up data segment).
  — TR. Type set to 11 and S set to 0 (busy 32-bit task-state segment).
- The DPL is set as follows:
  — CS, SS, and TR. Set to 0. The current privilege level (CPL) will be 0 after the VM exit completes.
  — DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 0.
- The P bit is set as follows:
  — CS, TR. Set to 1.
  — SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 1.
- On processors that support Intel 64 architecture, CS.L is loaded with the setting of the "host address-space size" VM-exit control. Because the value of this control is also loaded into IA32_EFER.LMA (see Section 27.5.1), no VM exit is ever to compatibility mode (which requires IA32_EFER.LMA = 1 and CS.L = 0).
- D/B.

1. Software can determine the number N by executing CPUID with 80000008H in EAX. The number of linear-address bits supported is returned in bits 15:8 of EAX.

  - CS. Loaded with the inverse of the setting of the "host address-space size" VM-exit control. For example, if that control is 0, indicating a 32-bit guest, CS.D/B is set to 1.
  - SS. Set to 1.
  - DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 1.
  - TR. Set to 0.
- G.
  - CS. Set to 1.
  - SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 1.
  - TR. Set to 0.

The host-state area does not contain a selector field for LDTR. LDTR is established as follows on all VM exits: the selector is cleared to 0000H, the segment is marked unusable and is otherwise undefined (although the base address is always canonical).

The base addresses for GDTR and IDTR are loaded from the GDTR base-address field and the IDTR base-address field, respectively. If the processor supports the Intel 64 architecture and the processor supports N < 64 linear-address bits, each of bits 63:N of each base address is set to the value of bit N–1 of that base address. The GDTR and IDTR limits are each set to FFFFH.

### 27.5.3 Loading Host RIP, RSP, and RFLAGS

RIP and RSP are loaded from the RIP field and the RSP field, respectively. RFLAGS is cleared, except bit 1, which is always set.

### 27.5.4 Checking and Loading Host Page-Directory-Pointer-Table Entries

If CR0.PG = 1, CR4.PAE = 1, and IA32_EFER.LMA = 0, the logical processor uses **PAE paging**. See Section 4.4 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.[1] When in PAE paging is in use, the physical address in CR3 references a table of **page-directory-pointer-table entries** (PDPTEs). A MOV to CR3 when PAE paging is in use checks the validity of the PDPTEs and, if they are valid, loads them into the processor (into internal, non-architectural registers).

A VM exit is to a VMM that uses PAE paging if (1) bit 5 (corresponding to CR4.PAE) is set in the CR4 field in the host-state area of the VMCS; and (2) the "host address-space size" VM-exit control is 0. Such a VM exit may check the validity of the PDPTEs referenced by the CR3 field in the host-state area of the VMCS. Such a VM exit must check their validity if either (1) PAE paging was not in use before the VM exit; or (2) the value of CR3 is changing as a result of the VM exit. A VM exit to a VMM that does not use PAE paging must not check the validity of the PDPTEs.

A VM exit that checks the validity of the PDPTEs uses the same checks that are used when CR3 is loaded with MOV to CR3 when PAE paging is in use. If MOV to CR3 would cause a general-protection exception due to the PDPTEs that would be loaded (e.g., because a reserved bit is set), a VMX abort occurs (see Section 27.7). If a VM exit to a VMM that uses PAE does not cause a VMX abort, the PDPTEs are loaded into the processor as would MOV to CR3, using the value of CR3 being load by the VM exit.

### 27.5.5 Updating Non-Register State

VM exits affect the non-register state of a logical processor as follows:

- A logical processor is always in the active state after a VM exit.
- Event blocking is affected as follows:
  - There is no blocking by STI or by MOV SS after a VM exit.

1. On processors that support Intel 64 architecture, the physical-address extension may support more than 36 physical-address bits. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

— VM exits caused directly by non-maskable interrupts (NMIs) cause blocking by NMI (see Table 24-3). Other VM exits do not affect blocking by NMI. (See Section 27.1 for the case in which an NMI causes a VM exit indirectly.)

- There are no pending debug exceptions after a VM exit.

Section 28.3 describes how the VMX architecture controls how a logical processor manages information in the TLBs and paging-structure caches. The following items detail how VM exits invalidate cached mappings:

- If the "enable VPID" VM-execution control is 0, the logical processor invalidates linear mappings and combined mappings associated with VPID 0000H (for all PCIDs); combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP).
- VM exits are not required to invalidate any guest-physical mappings, nor are they required to invalidate any linear mappings or combined mappings if the "enable VPID" VM-execution control is 1.

### 27.5.6 Clearing Address-Range Monitoring

The Intel 64 and IA-32 architectures allow software to monitor a specified address range using the MONITOR and MWAIT instructions. See Section 8.10.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*. VM exits clear any address-range monitoring that may be in effect.

## 27.6 LOADING MSRS

VM exits may load MSRs from the VM-exit MSR-load area (see Section 24.7.2). Specifically each entry in that area (up to the number specified in the VM-exit MSR-load count) is processed in order by loading the MSR indexed by bits 31:0 with the contents of bits 127:64 as they would be written by WRMSR.

Processing of an entry fails in any of the following cases:

- The value of bits 31:0 is either C0000100H (the IA32_FS_BASE MSR) or C0000101H (the IA32_GS_BASE MSR).
- The value of bits 31:8 is 000008H, meaning that the indexed MSR is one that allows access to an APIC register when the local APIC is in x2APIC mode.
- The value of bits 31:0 indicates an MSR that can be written only in system-management mode (SMM) and the VM exit will not end in SMM. (IA32_SMM_MONITOR_CTL is an MSR that can be written only in SMM.)
- The value of bits 31:0 indicates an MSR that cannot be loaded on VM exits for model-specific reasons. A processor may prevent loading of certain MSRs even if they can normally be written by WRMSR. Such model-specific behavior is documented in Chapter 35.
- Bits 63:32 are not all 0.
- An attempt to write bits 127:64 to the MSR indexed by bits 31:0 of the entry would cause a general-protection exception if executed via WRMSR with CPL = 0.[1]

If processing fails for any entry, a VMX abort occurs. See Section 27.7.

If any MSR is being loaded in such a way that would architecturally require a TLB flush, the TLBs are updated so that, after VM exit, the logical processor does not use any translations that were cached before the transition.

## 27.7 VMX ABORTS

A problem encountered during a VM exit leads to a **VMX abort**. A VMX abort takes a logical processor into a shut-down state as described below.

1. Note the following about processors that support Intel 64 architecture. If CR0.PG = 1, WRMSR to the IA32_EFER MSR causes a general-protection exception if it would modify the LME bit. Since CR0.PG is always 1 in VMX operation, the IA32_EFER MSR should not be included in the VM-exit MSR-load area for the purpose of modifying the LME bit.

A VMX abort does not modify the VMCS data in the VMCS region of any active VMCS. The contents of these data are thus suspect after the VMX abort.

On a VMX abort, a logical processor saves a nonzero 32-bit VMX-abort indicator field at byte offset 4 in the VMCS region of the VMCS whose misconfiguration caused the failure (see Section 24.2). The following values are used:

1. There was a failure in saving guest MSRs (see Section 27.4).
2. Host checking of the page-directory-pointer-table entries (PDPTEs) failed (see Section 27.5.4).
3. The current VMCS has been corrupted (through writes to the corresponding VMCS region) in such a way that the logical processor cannot complete the VM exit properly.
4. There was a failure on loading host MSRs (see Section 27.6).
5. There was a machine-check event during VM exit (see Section 27.8).
6. The logical processor was in IA-32e mode before the VM exit and the "host address-space size" VM-entry control was 0 (see Section 27.5).

Some of these causes correspond to failures during the loading of state from the host-state area. Because the loading of such state may be done in any order (see Section 27.5) a VM exit that might lead to a VMX abort for multiple reasons (for example, the current VMCS may be corrupt and the host PDPTEs might not be properly configured). In such cases, the VMX-abort indicator could correspond to any one of those reasons.

A logical processor never reads the VMX-abort indicator in a VMCS region and writes it only with one of the non-zero values mentioned above. The VMX-abort indicator allows software on one logical processor to diagnose the VMX-abort on another. For this reason, it is recommended that software running in VMX root operation zero the VMX-abort indicator in the VMCS region of any VMCS that it uses.

After saving the VMX-abort indicator, operation of a logical processor experiencing a VMX abort depends on whether the logical processor is in SMX operation:[1]

- If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs. The error code used is 000DH, indicating "VMX abort." See *Intel® Trusted Execution Technology Measured Launched Environment Programming Guide*.
- If the logical processor is outside SMX operation, it issues a special bus cycle (to notify the chipset) and enters the **VMX-abort shutdown state**. RESET is the only event that wakes a logical processor from the VMX-abort shutdown state. The following events do not affect a logical processor in this state: machine-check events; INIT signals; external interrupts; non-maskable interrupts (NMIs); start-up IPIs (SIPIs); and system-management interrupts (SMIs).

## 27.8 MACHINE-CHECK EVENTS DURING VM EXIT

If a machine-check event occurs during VM exit, one of the following occurs:

- The machine-check event is handled as if it occurred before the VM exit:
  - If CR4.MCE = 0, operation of the logical processor depends on whether the logical processor is in SMX operation:[2]
    - If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs. The error code used is 000CH, indicating "unrecoverable machine-check condition."
    - If the logical processor is outside SMX operation, it goes to the shutdown state.

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.
2. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.

  - If CR4.MCE = 1, a machine-check exception (#MC) is generated:
    - If bit 18 (#MC) of the exception bitmap is 0, the exception is delivered through the guest IDT.
    - If bit 18 of the exception bitmap is 1, the exception causes a VM exit.
- The machine-check event is handled after VM exit completes:
  - If the VM exit ends with CR4.MCE = 0, operation of the logical processor depends on whether the logical processor is in SMX operation:
    - If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs with error code 000CH (unrecoverable machine-check condition).
    - If the logical processor is outside SMX operation, it goes to the shutdown state.
  - If the VM exit ends with CR4.MCE = 1, a machine-check exception (#MC) is delivered through the host IDT.
- A VMX abort is generated (see Section 27.7). The logical processor blocks events as done normally in VMX abort. The VMX abort indicator is 5, for "machine-check event during VM exit."

The first option is not used if the machine-check event occurs after any host state has been loaded. The second option is used only if VM entry is able to load all host state.

# CHAPTER 28
# VMX SUPPORT FOR ADDRESS TRANSLATION

The architecture for VMX operation includes two features that support address translation: virtual-processor identifiers (VPIDs) and the extended page-table mechanism (EPT). VPIDs are a mechanism for managing translations of linear addresses. EPT defines a layer of address translation that augments the translation of linear addresses.

Section 28.1 details the architecture of VPIDs. Section 28.2 provides the details of EPT. Section 28.3 explains how a logical processor may cache information from the paging structures, how it may use that cached information, and how software can managed the cached information.

## 28.1 VIRTUAL PROCESSOR IDENTIFIERS (VPIDS)

The original architecture for VMX operation required VMX transitions to flush the TLBs and paging-structure caches. This ensured that translations cached for the old linear-address space would not be used after the transition.

Virtual-processor identifiers (**VPIDs**) introduce to VMX operation a facility by which a logical processor may cache information for multiple linear-address spaces. When VPIDs are used, VMX transitions may retain cached information and the logical processor switches to a different linear-address space.

Section 28.3 details the mechanisms by which a logical processor manages information cached for multiple address spaces. A logical processor may tag some cached information with a 16-bit VPID. This section specifies how the current VPID is determined at any point in time:

- The current VPID is 0000H in the following situations:
  - — Outside VMX operation. (This includes operation in system-management mode under the default treatment of SMIs and SMM with VMX operation; see Section 34.14.)
  - — In VMX root operation.
  - — In VMX non-root operation when the "enable VPID" VM-execution control is 0.
- If the logical processor is in VMX non-root operation and the "enable VPID" VM-execution control is 1, the current VPID is the value of the VPID VM-execution control field in the VMCS. (VM entry ensures that this value is never 0000H; see Section 26.2.1.1.)

VPIDs and PCIDs (see Section 4.10.1) can be used concurrently. When this is done, the processor associates cached information with both a VPID and a PCID. Such information is used only if the current VPID and PCID **both** match those associated with the cached information.

## 28.2 THE EXTENDED PAGE TABLE MECHANISM (EPT)

The extended page-table mechanism (**EPT**) is a feature that can be used to support the virtualization of physical memory. When EPT is in use, certain addresses that would normally be treated as physical addresses (and used to access memory) are instead treated as **guest-physical addresses**. Guest-physical addresses are translated by traversing a set of **EPT paging structures** to produce physical addresses that are used to access memory.

- Section 28.2.1 gives an overview of EPT.
- Section 28.2.2 describes operation of EPT-based address translation.
- Section 28.2.3 discusses VM exits that may be caused by EPT.
- Section 28.2.5 describes interactions between EPT and memory typing.

### 28.2.1 EPT Overview

EPT is used when the "enable EPT" VM-execution control is 1.[1] It translates the guest-physical addresses used in VMX non-root operation and those used by VM entry for event injection.

The translation from guest-physical addresses to physical addresses is determined by a set of **EPT paging structures**. The EPT paging structures are similar to those used to translate linear addresses while the processor is in IA-32e mode. Section 28.2.2 gives the details of the EPT paging structures.

If CR0.PG = 1, linear addresses are translated through paging structures referenced through control register CR3. While the "enable EPT" VM-execution control is 1, these are called **guest paging structures**. There are no guest paging structures if CR0.PG = 0.[1]

When the "enable EPT" VM-execution control is 1, the identity of **guest-physical addresses** depends on the value of CR0.PG:

- If CR0.PG = 0, each linear address is treated as a guest-physical address.
- If CR0.PG = 1, guest-physical addresses are those derived from the contents of control register CR3 and the guest paging structures. (This includes the values of the PDPTEs, which logical processors store in internal, non-architectural registers.) The latter includes (in page-table entries and in other paging-structure entries for which bit 7—PS—is 1) the addresses to which linear addresses are translated by the guest paging structures.

If CR0.PG = 1, the translation of a linear address to a physical address requires multiple translations of guest-physical addresses using EPT. Assume, for example, that CR4.PAE = CR4.PSE = 0. The translation of a 32-bit linear address then operates as follows:

- Bits 31:22 of the linear address select an entry in the guest page directory located at the guest-physical address in CR3. The guest-physical address of the guest page-directory entry (PDE) is translated through EPT to determine the guest PDE's physical address.
- Bits 21:12 of the linear address select an entry in the guest page table located at the guest-physical address in the guest PDE. The guest-physical address of the guest page-table entry (PTE) is translated through EPT to determine the guest PTE's physical address.
- Bits 11:0 of the linear address is the offset in the page frame located at the guest-physical address in the guest PTE. The guest-physical address determined by this offset is translated through EPT to determine the physical address to which the original linear address translates.

In addition to translating a guest-physical address to a physical address, EPT specifies the privileges that software is allowed when accessing the address. Attempts at disallowed accesses are called **EPT violations** and cause VM exits. See Section 28.2.3.

A logical processor uses EPT to translate guest-physical addresses only when those addresses are used to access memory. This principle implies the following:

- The MOV to CR3 instruction loads CR3 with a guest-physical address. Whether that address is translated through EPT depends on whether PAE paging is being used.[2]
  - — If PAE paging is not being used, the instruction does not use that address to access memory and does **not** cause it to be translated through EPT. (If CR0.PG = 1, the address will be translated through EPT on the next memory accessing using a linear address.)
  - — If PAE paging is being used, the instruction loads the four (4) page-directory-pointer-table entries (PDPTEs) from that address and it **does** cause the address to be translated through EPT.
- Section 4.4.1 identifies executions of MOV to CR0 and MOV to CR4 that load the PDPTEs from the guest-physical address in CR3. Such executions cause that address to be translated through EPT.
- The PDPTEs contain guest-physical addresses. The instructions that load the PDPTEs (see above) do not use those addresses to access memory and do **not** cause them to be translated through EPT. The address in a PDPTE will be translated through EPT on the next memory accessing using a linear address that uses that PDPTE.

---

1. "Enable EPT" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, the logical processor operates as if the "enable EPT" VM-execution control were 0. See Section 24.6.2.

1. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG can be 0 in VMX non-root operation only if the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

2. A logical processor uses PAE paging if CR0.PG = 1, CR4.PAE = 1 and IA32_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

### 28.2.2 EPT Translation Mechanism

The EPT translation mechanism uses only bits 47:0 of each guest-physical address.[1] It uses a page-walk length of 4, meaning that at most 4 EPT paging-structure entries are accessed to translate a guest-physical address.[2]

These 48 bits are partitioned by the logical processor to traverse the EPT paging structures:

- A 4-KByte naturally aligned EPT PML4 table is located at the physical address specified in bits 51:12 of the extended-page-table pointer (EPTP), a VM-execution control field (see Table 24-8 in Section 24.6.11). An EPT PML4 table comprises 512 64-bit entries (EPT PML4Es). An EPT PML4E is selected using the physical address defined as follows:
  - Bits 63:52 are all 0.
  - Bits 51:12 are from the EPTP.
  - Bits 11:3 are bits 47:39 of the guest-physical address.
  - Bits 2:0 are all 0.

  Because an EPT PML4E is identified using bits 47:39 of the guest-physical address, it controls access to a 512-GByte region of the guest-physical-address space. The format of an EPT PML4E is given in Table 28-1.

**Table 28-1. Format of an EPT PML4 Entry (PML4E)**

| Bit Position(s) | Contents |
|---|---|
| 0 | Read access; indicates whether reads are allowed from the 512-GByte region controlled by this entry |
| 1 | Write access; indicates whether writes are allowed to the 512-GByte region controlled by this entry |
| 2 | Execute access; indicates whether instruction fetches are allowed from the 512-GByte region controlled by this entry |
| 7:3 | Reserved (must be 0) |
| 8 | If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 512-GByte region controlled by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0 |
| 11:9 | Ignored |
| (N–1):12 | Physical address of 4-KByte aligned EPT page-directory-pointer table referenced by this entry[1] |
| 51:N | Reserved (must be 0) |
| 63:52 | Ignored |

NOTES:

1. N is the physical-address width supported by the processor. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

- A 4-KByte naturally aligned EPT page-directory-pointer table is located at the physical address specified in bits 51:12 of the EPT PML4E. An EPT page-directory-pointer table comprises 512 64-bit entries (EPT PDPTEs). An EPT PDPTE is selected using the physical address defined as follows:
  - Bits 63:52 are all 0.
  - Bits 51:12 are from the EPT PML4E.

1. No processors supporting the Intel 64 architecture support more than 48 physical-address bits. Thus, no such processor can produce a guest-physical address with more than 48 bits. An attempt to use such an address causes a page fault. An attempt to load CR3 with such an address causes a general-protection fault. If PAE paging is being used, an attempt to load CR3 that would load a PDPTE with such an address causes a general-protection fault.
2. Future processors may include support for other EPT page-walk lengths. Software should read the VMX capability MSR IA32_VMX_EPT_VPID_CAP (see Appendix A.10) to determine what EPT page-walk lengths are supported.

— Bits 11:3 are bits 38:30 of the guest-physical address.

— Bits 2:0 are all 0.

Because an EPT PDPTE is identified using bits 47:30 of the guest-physical address, it controls access to a 1-GByte region of the guest-physical-address space. Use of the EPT PDPTE depends on the value of bit 7 in that entry:[1]

- If bit 7 of the EPT PDPTE is 1, the EPT PDPTE maps a 1-GByte page. The final physical address is computed as follows:
  — Bits 63:52 are all 0.
  — Bits 51:30 are from the EPT PDPTE.
  — Bits 29:0 are from the original guest-physical address.

  The format of an EPT PDPTE that maps a 1-GByte page is given in Table 28-2.

**Table 28-2. Format of an EPT Page-Directory-Pointer-Table Entry (PDPTE) that Maps a 1-GByte Page**

| Bit Position(s) | Contents |
|---|---|
| 0 | Read access; indicates whether reads are allowed from the 1-GByte page referenced by this entry |
| 1 | Write access; indicates whether writes are allowed to the 1-GByte page referenced by this entry |
| 2 | Execute access; indicates whether instruction fetches are allowed from the 1-GByte page referenced by this entry |
| 5:3 | EPT memory type for this 1-GByte page (see Section 28.2.5) |
| 6 | Ignore PAT memory type for this 1-GByte page (see Section 28.2.5) |
| 7 | Must be 1 (otherwise, this entry references an EPT page directory) |
| 8 | If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 1-GByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0 |
| 9 | If bit 6 of EPTP is 1, dirty flag for EPT; indicates whether software has written to the 1-GByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0 |
| 11:10 | Ignored |
| 29:12 | Reserved (must be 0) |
| (N–1):30 | Physical address of the 1-GByte page referenced by this entry[1] |
| 51:N | Reserved (must be 0) |
| 62:52 | Ignored |
| 63 | Suppress #VE. If the "EPT-violation #VE" VM-execution control is 1, EPT violations caused by accesses to this page are convertible to virtualization exceptions only if this bit is 0 (see Section 25.5.6.1). If "EPT-violation #VE" VM-execution control is 0, this bit is ignored. |

**NOTES:**

1. N is the physical-address width supported by the logical processor.

- If bit 7 of the EPT PDPTE is 0, a 4-KByte naturally aligned EPT page directory is located at the physical address specified in bits 51:12 of the EPT PDPTE. The format of an EPT PDPTE that references an EPT page directory is given in Table 28-3.

1. Not all processors allow bit 7 of an EPT PDPTE to be set to 1. Software should read the VMX capability MSR IA32_VMX_EPT_VPID_CAP (see Appendix A.10) to determine whether this is allowed.

**Table 28-3. Format of an EPT Page-Directory-Pointer-Table Entry (PDPTE) that References an EPT Page Directory**

| Bit Position(s) | Contents |
|---|---|
| 0 | Read access; indicates whether reads are allowed from the 1-GByte region controlled by this entry |
| 1 | Write access; indicates whether writes are allowed to the 1-GByte region controlled by this entry |
| 2 | Execute access; indicates whether instruction fetches are allowed from the 1-GByte region controlled by this entry |
| 7:3 | Reserved (must be 0) |
| 8 | If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 1-GByte region controlled by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0 |
| 11:9 | Ignored |
| (N–1):12 | Physical address of 4-KByte aligned EPT page directory referenced by this entry[1] |
| 51:N | Reserved (must be 0) |
| 63:52 | Ignored |

**NOTES:**

1. N is the physical-address width supported by the logical processor.

An EPT page-directory comprises 512 64-bit entries (PDEs). An EPT PDE is selected using the physical address defined as follows:

— Bits 63:52 are all 0.

— Bits 51:12 are from the EPT PDPTE.

— Bits 11:3 are bits 29:21 of the guest-physical address.

— Bits 2:0 are all 0.

Because an EPT PDE is identified using bits 47:21 of the guest-physical address, it controls access to a 2-MByte region of the guest-physical-address space. Use of the EPT PDE depends on the value of bit 7 in that entry:

- If bit 7 of the EPT PDE is 1, the EPT PDE maps a 2-MByte page. The final physical address is computed as follows:

  — Bits 63:52 are all 0.

  — Bits 51:21 are from the EPT PDE.

  — Bits 20:0 are from the original guest-physical address.

  The format of an EPT PDE that maps a 2-MByte page is given in Table 28-4.

- If bit 7 of the EPT PDE is 0, a 4-KByte naturally aligned EPT page table is located at the physical address specified in bits 51:12 of the EPT PDE. The format of an EPT PDE that references an EPT page table is given in Table 28-5.

  An EPT page table comprises 512 64-bit entries (PTEs). An EPT PTE is selected using a physical address defined as follows:

  — Bits 63:52 are all 0.

  — Bits 51:12 are from the EPT PDE.

  — Bits 11:3 are bits 20:12 of the guest-physical address.

  — Bits 2:0 are all 0.

- Because an EPT PTE is identified using bits 47:12 of the guest-physical address, every EPT PTE maps a 4-KByte page. The final physical address is computed as follows:

  — Bits 63:52 are all 0.

**Table 28-4. Format of an EPT Page-Directory Entry (PDE) that Maps a 2-MByte Page**

| Bit Position(s) | Contents |
|---|---|
| 0 | Read access; indicates whether reads are allowed from the 2-MByte page referenced by this entry |
| 1 | Write access; indicates whether writes are allowed to the 2-MByte page referenced by this entry |
| 2 | Execute access; indicates whether instruction fetches are allowed from the 2-MByte page referenced by this entry |
| 5:3 | EPT memory type for this 2-MByte page (see Section 28.2.5) |
| 6 | Ignore PAT memory type for this 2-MByte page (see Section 28.2.5) |
| 7 | Must be 1 (otherwise, this entry references an EPT page table) |
| 8 | If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 2-MByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0 |
| 9 | If bit 6 of EPTP is 1, dirty flag for EPT; indicates whether software has written to the 2-MByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0 |
| 11:10 | Ignored |
| 20:12 | Reserved (must be 0) |
| (N–1):21 | Physical address of the 2-MByte page referenced by this entry[1] |
| 51:N | Reserved (must be 0) |
| 62:52 | Ignored |
| 63 | Suppress #VE. If the "EPT-violation #VE" VM-execution control is 1, EPT violations caused by accesses to this page are convertible to virtualization exceptions only if this bit is 0 (see Section 25.5.6.1). If "EPT-violation #VE" VM-execution control is 0, this bit is ignored. |

**NOTES:**

1. N is the physical-address width supported by the logical processor.

— Bits 51:12 are from the EPT PTE.

— Bits 11:0 are from the original guest-physical address.

The format of an EPT PTE is given in Table 28-6.

If bits 2:0 of an EPT paging-structure entry are all 0, the entry is **not present**. The processor ignores bits 62:3 and uses the entry neither to reference another EPT paging-structure entry nor to produce a physical address. A reference using a guest-physical address whose translation encounters an EPT paging-structure that is not present causes an EPT violation (see Section 28.2.3.2). (If the "EPT-violation #VE" VM-execution control is 1, the EPT violation is convertible to a virtualization exception only if bit 63 is 0; see Section 25.5.6.1. If the "EPT-violation #VE" VM-execution control is 0, this bit is ignored.)

The discussion above describes how the EPT paging structures reference each other and how the logical processor traverses those structures when translating a guest-physical address. It does not cover all details of the translation process. Additional details are provided as follows:

- Situations in which the translation process may lead to VM exits (sometimes before the process completes) are described in Section 28.2.3.
- Interactions between the EPT translation mechanism and memory typing are described in Section 28.2.5.

Figure 28-1 gives a summary of the formats of the EPTP and the EPT paging-structure entries. For the EPT paging structure entries, it identifies separately the format of entries that map pages, those that reference other EPT paging structures, and those that do neither because they are "not present"; bits 2:0 and bit 7 are highlighted because they determine how a paging-structure entry is used.

Table 28-5. Format of an EPT Page-Directory Entry (PDE) that References an EPT Page Table

| Bit Position(s) | Contents |
|---|---|
| 0 | Read access; indicates whether reads are allowed from the 2-MByte region controlled by this entry |
| 1 | Write access; indicates whether writes are allowed to the 2-MByte region controlled by this entry |
| 2 | Execute access; indicates whether instruction fetches are allowed from the 2-MByte region controlled by this entry |
| 6:3 | Reserved (must be 0) |
| 7 | Must be 0 (otherwise, this entry maps a 2-MByte page) |
| 8 | If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 2-MByte region controlled by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0 |
| 11:9 | Ignored |
| (N–1):12 | Physical address of 4-KByte aligned EPT page table referenced by this entry[1] |
| 51:N | Reserved (must be 0) |
| 63:52 | Ignored |

NOTES:
1. N is the physical-address width supported by the logical processor.

## 28.2.3 EPT-Induced VM Exits

Accesses using guest-physical addresses may cause VM exits due to **EPT misconfigurations** and **EPT violations**. An EPT misconfiguration occurs when, in the course of translating a guest-physical address, the logical processor encounters an EPT paging-structure entry that contains an unsupported value. An EPT violation occurs when there is no EPT misconfiguration but the EPT paging-structure entries disallow an access using the guest-physical address.

EPT misconfigurations and EPT violations occur only due to an attempt to access memory with a guest-physical address. Loading CR3 with a guest-physical address with the MOV to CR3 instruction can cause neither an EPT configuration nor an EPT violation until that address is used to access a paging structure.[1]

If the "EPT-violation #VE" VM-execution control is 1, certain EPT violations may cause virtualization exceptions instead of VM exits. See Section 25.5.6.1.

### 28.2.3.1 EPT Misconfigurations

AN EPT misconfiguration occurs if any of the following is identified while translating a guest-physical address:

- The value of bits 2:0 of an EPT paging-structure entry is either 010b (write-only) or 110b (write/execute).
- The value of bits 2:0 of an EPT paging-structure entry is 100b (execute-only) and this value is not supported by the logical processor. Software should read the VMX capability MSR IA32_VMX_EPT_VPID_CAP to determine whether this value is supported (see Appendix A.10).
- The value of bits 2:0 of an EPT paging-structure entry is not 000b (the entry is present) **and** one of the following holds:

1. If the logical processor is using PAE paging—because CR0.PG = CR4.PAE = 1 and IA32_EFER.LMA = 0—the MOV to CR3 instruction loads the PDPTEs from memory using the guest-physical address being loaded into CR3. In this case, therefore, the MOV to CR3 instruction may cause an EPT misconfiguration or an EPT violation.

**Table 28-6. Format of an EPT Page-Table Entry**

| Bit Position(s) | Contents |
|---|---|
| 0 | Read access; indicates whether reads are allowed from the 4-KByte page referenced by this entry |
| 1 | Write access; indicates whether writes are allowed to the 4-KByte page referenced by this entry |
| 2 | Execute access; indicates whether instruction fetches are allowed from the 4-KByte page referenced by this entry |
| 5:3 | EPT memory type for this 4-KByte page (see Section 28.2.5) |
| 6 | Ignore PAT memory type for this 4-KByte page (see Section 28.2.5) |
| 7 | Ignored |
| 8 | If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 4-KByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0 |
| 9 | If bit 6 of EPTP is 1, dirty flag for EPT; indicates whether software has written to the 4-KByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0 |
| 11:10 | Ignored |
| (N–1):12 | Physical address of the 4-KByte page referenced by this entry[1] |
| 51:N | Reserved (must be 0) |
| 62:52 | Ignored |
| 63 | Suppress #VE. If the "EPT-violation #VE" VM-execution control is 1, EPT violations caused by accesses to this page are convertible to virtualization exceptions only if this bit is 0 (see Section 25.5.6.1). If "EPT-violation #VE" VM-execution control is 0, this bit is ignored. |

**NOTES:**

1. N is the physical-address width supported by the logical processor.

— A reserved bit is set. This includes the setting of a bit in the range 51:12 that is beyond the logical processor's physical-address width.[1] See Section 28.2.2 for details of which bits are reserved in which EPT paging-structure entries.

— The entry is the last one used to translate a guest physical address (either an EPT PDE with bit 7 set to 1 or an EPT PTE) and the value of bits 5:3 (EPT memory type) is 2, 3, or 7 (these values are reserved).

EPT misconfigurations result when an EPT paging-structure entry is configured with settings reserved for future functionality. Software developers should be aware that such settings may be used in the future and that an EPT paging-structure entry that causes an EPT misconfiguration on one processor might not do so in the future.

### 28.2.3.2 EPT Violations

An EPT violation may occur during an access using a guest-physical address whose translation does not cause an EPT misconfiguration. An EPT violation occurs in any of the following situations:

- Translation of the guest-physical address encounters an EPT paging-structure entry that is not present (see Section 28.2.2).
- The access is a data read and bit 0 was clear in any of the EPT paging-structure entries used to translate the guest-physical address. Reads by the logical processor of guest paging structures to translate a linear address are considered to be data reads.

1. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

| 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 | 55 | 54 | 53 | 52 | 51 | M[1] | M-1 | 32 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |

**Figure 28-1. Formats of EPTP and EPT Paging-Structure Entries**

**NOTES:**

1. M is an abbreviation for MAXPHYADDR.
2. See Section 24.6.11 for details of the EPTP.
3. Suppress #VE. If the "EPT-violation #VE" VM-execution control is 0, this bit is ignored.

- The access is a data write and bit 1 was clear in any of the EPT paging-structure entries used to translate the guest-physical address. Writes by the logical processor to guest paging structures to update accessed and dirty flags are considered to be data writes.

  If bit 6 of the EPT pointer (EPTP) is 1 (enabling accessed and dirty flags for EPT), processor accesses to guest paging-structure entries are treated as writes with regard to EPT violations. Thus, if bit 1 is clear in any of the EPT paging-structure entries used to translate the guest-physical address of a guest paging-structure entry, an attempt to use that entry to translate a linear address causes an EPT violation.

  (This does not apply to loads of the PDPTE registers by the MOV to CR instruction for PAE paging; see Section 4.4.1. Those loads of guest PDPTEs are treated as reads and do not cause EPT violations due to a guest-physical address not being writable.)
- The access is an instruction fetch and bit 2 was clear in any of the EPT paging-structure entries used to translate the guest-physical address.

### 28.2.3.3 Prioritization of EPT-Induced VM Exits

The translation of a linear address to a physical address requires one or more translations of guest-physical addresses using EPT (see Section 28.2.1). This section specifies the relative priority of EPT-induced VM exits with respect to each other and to other events that may be encountered when accessing memory using a linear address.

For an access to a guest-physical address, determination of whether an EPT misconfiguration or an EPT violation occurs is based on an iterative process:[1]

1. An EPT paging-structure entry is read (initially, this is an EPT PML4 entry):
   a. If the entry is not present (bits 2:0 are all 0), an EPT violation occurs.
   b. If the entry is present but its contents are not configured properly (see Section 28.2.3.1), an EPT misconfiguration occurs.
   c. If the entry is present and its contents are configured properly, operation depends on whether the entry references another EPT paging structure (whether it is an EPT PDE with bit 7 set to 1 or an EPT PTE):
      i) If the entry does reference another EPT paging structure, an entry from that structure is accessed; step 1 is executed for that other entry.
      ii) Otherwise, the entry is used to produce the ultimate physical address (the translation of the original guest-physical address); step 2 is executed.
2. Once the ultimate physical address is determined, the privileges determined by the EPT paging-structure entries are evaluated:
   a. If the access to the guest-physical address is not allowed by these privileges (see Section 28.2.3.2), an EPT violation occurs.
   b. If the access to the guest-physical address is allowed by these privileges, memory is accessed using the ultimate physical address.

If CR0.PG = 1, the translation of a linear address is also an iterative process, with the processor first accessing an entry in the guest paging structure referenced by the guest-physical address in CR3 (or, if PAE paging is in use, the guest-physical address in the appropriate PDPTE register), then accessing an entry in another guest paging structure referenced by the guest-physical address in the first guest paging-structure entry, etc. Each guest-physical address is itself translated using EPT and may cause an EPT-induced VM exit. The following items detail how page faults and EPT-induced VM exits are recognized during this iterative process:

1. An attempt is made to access a guest paging-structure entry with a guest-physical address (initially, the address in CR3 or PDPTE register).
   a. If the access fails because of an EPT misconfiguration or an EPT violation (see above), an EPT-induced VM exit occurs.
   b. If the access does not cause an EPT-induced VM exit, bit 0 (the present flag) of the entry is consulted:
      i) If the present flag is 0 or any reserved bit is set, a page fault occurs.
      ii) If the present flag is 1, no reserved bit is set, operation depends on whether the entry references another guest paging structure (whether it is a guest PDE with PS = 1 or a guest PTE):
         - If the entry does reference another guest paging structure, an entry from that structure is accessed; step 1 is executed for that other entry.
         - Otherwise, the entry is used to produce the ultimate guest-physical address (the translation of the original linear address); step 2 is executed.
2. Once the ultimate guest-physical address is determined, the privileges determined by the guest paging-structure entries are evaluated:
   a. If the access to the linear address is not allowed by these privileges (e.g., it was a write to a read-only page), a page fault occurs.
   b. If the access to the linear address is allowed by these privileges, an attempt is made to access memory at the ultimate guest-physical address:

1. This is a simplification of the more detailed description given in Section 28.2.2.

i) If the access fails because of an EPT misconfiguration or an EPT violation (see above), an EPT-induced VM exit occurs.

ii) If the access does not cause an EPT-induced VM exit, memory is accessed using the ultimate physical address (the translation, using EPT, of the ultimate guest-physical address).

If CR0.PG = 0, a linear address is treated as a guest-physical address and is translated using EPT (see above). This process, if it completes without an EPT violation or EPT misconfiguration, produces a physical address and determines the privileges allowed by the EPT paging-structure entries. If these privileges do not allow the access to the physical address (see Section 28.2.3.2), an EPT violation occurs. Otherwise, memory is accessed using the physical address.

## 28.2.4 Accessed and Dirty Flags for EPT

The Intel 64 architecture supports **accessed and dirty flags** in ordinary paging-structure entries (see Section 4.8). Some processors also support corresponding flags in EPT paging-structure entries. Software should read the VMX capability MSR IA32_VMX_EPT_VPID_CAP (see Appendix A.10) to determine whether the processor supports this feature.

Software can enable accessed and dirty flags for EPT using bit 6 of the extended-page-table pointer (EPTP), a VM-execution control field (see Table 24-8 in Section 24.6.11). If this bit is 1, the processor will set the accessed and dirty flags for EPT as described below. In addition, setting this flag causes processor accesses to guest paging-structure entries to be treated as writes (see below and Section 28.2.3.2).

For any EPT paging-structure entry that is used during guest-physical-address translation, bit 8 is the accessed flag. For a EPT paging-structure entry that maps a page (as opposed to referencing another EPT paging structure), bit 9 is the dirty flag.

Whenever the processor uses an EPT paging-structure entry as part of guest-physical-address translation, it sets the accessed flag in that entry (if it is not already set).

Whenever there is a write to a guest-physical address, the processor sets the dirty flag (if it is not already set) in the EPT paging-structure entry that identifies the final physical address for the guest-physical address (either an EPT PTE or an EPT paging-structure entry in which bit 7 is 1).

When accessed and dirty flags for EPT are enabled, processor accesses to guest paging-structure entries are treated as writes (see Section 28.2.3.2). Thus, such an access will cause the processor to set the dirty flag in the EPT paging-structure entry that identifies the final physical address of the guest paging-structure entry.

(This does not apply to loads of the PDPTE registers for PAE paging by the MOV to CR instruction; see Section 4.4.1. Those loads of guest PDPTEs are treated as reads and do not cause the processor to set the dirty flag in any EPT paging-structure entry.)

These flags are "sticky," meaning that, once set, the processor does not clear them; only software can clear them.

A processor may cache information from the EPT paging-structure entries in TLBs and paging-structure caches (see Section 28.3). This fact implies that, if software changes an accessed flag or a dirty flag from 1 to 0, the processor might not set the corresponding bit in memory on a subsequent access using an affected guest-physical address.

## 28.2.5 EPT and Memory Typing

This section specifies how a logical processor determines the memory type use for a memory access while EPT is in use. (See Chapter 11, "Memory Cache Control" of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A* for details of memory typing in the Intel 64 architecture.) Section 28.2.5.1 explains how the memory type is determined for accesses to the EPT paging structures. Section 28.2.5.2 explains how the memory type is determined for an access using a guest-physical address that is translated using EPT.

### 28.2.5.1 Memory Type Used for Accessing EPT Paging Structures

This section explains how the memory type is determined for accesses to the EPT paging structures. The determination is based first on the value of bit 30 (cache disable—CD) in control register CR0:

- If CR0.CD = 0, the memory type used for any such reference is the EPT paging-structure memory type, which is specified in bits 2:0 of the extended-page-table pointer (EPTP), a VM-execution control field (see Section 24.6.11). A value of 0 indicates the uncacheable type (UC), while a value of 6 indicates the write-back type (WB). Other values are reserved.
- If CR0.CD = 1, the memory type used for any such reference is uncacheable (UC).

The MTRRs have no effect on the memory type used for an access to an EPT paging structure.

### 28.2.5.2 Memory Type Used for Translated Guest-Physical Addresses

The **effective memory type** of a memory access using a guest-physical address (an access that is translated using EPT) is the memory type that is used to access memory. The effective memory type is based on the value of bit 30 (cache disable—CD) in control register CR0; the **last** EPT paging-structure entry used to translate the guest-physical address (either an EPT PDE with bit 7 set to 1 or an EPT PTE); and the PAT memory type (see below):

- The **PAT memory type** depends on the value of CR0.PG:
  - If CR0.PG = 0, the PAT memory type is WB (writeback).[1]
  - If CR0.PG = 1, the PAT memory type is the memory type selected from the IA32_PAT MSR as specified in Section 11.12.3, "Selecting a Memory Type from the PAT".[2]
- The **EPT memory type** is specified in bits 5:3 of the last EPT paging-structure entry: 0 = UC; 1 = WC; 4 = WT; 5 = WP; and 6 = WB. Other values are reserved and cause EPT misconfigurations (see Section 28.2.3).
- If CR0.CD = 0, the effective memory type depends upon the value of bit 6 of the last EPT paging-structure entry:
  - If the value is 0, the effective memory type is the combination of the EPT memory type and the PAT memory type specified in Table 11-7 in Section 11.5.2.2, using the EPT memory type in place of the MTRR memory type.
  - If the value is 1, the memory type used for the access is the EPT memory type. The PAT memory type is ignored.
- If CR0.CD = 1, the effective memory type is UC.

The MTRRs have no effect on the memory type used for an access to a guest-physical address.

## 28.3 CACHING TRANSLATION INFORMATION

Processors supporting Intel® 64 and IA-32 architectures may accelerate the address-translation process by caching on the processor data from the structures in memory that control that process. Such caching is discussed in Section 4.10, "Caching Translation Information" in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A.* The current section describes how this caching interacts with the VMX architecture.

The VPID and EPT features of the architecture for VMX operation augment this caching architecture. EPT defines the guest-physical address space and defines translations to that address space (from the linear-address space) and from that address space (to the physical-address space). Both features control the ways in which a logical processor may create and use information cached from the paging structures.

Section 28.3.1 describes the different kinds of information that may be cached. Section 28.3.2 specifies when such information may be cached and how it may be used. Section 28.3.3 details how software can invalidate cached information.

---

1. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG can be 0 in VMX non-root operation only if the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
2. Table 11-11 in Section 11.12.3, "Selecting a Memory Type from the PAT" illustrates how the PAT memory type is selected based on the values of the PAT, PCD, and PWT bits in a page-table entry (or page-directory entry with PS = 1). For accesses to a guest paging-structure entry X, the PAT memory type is selected from the table by using a value of 0 for the PAT bit with the values of PCD and PWT from the paging-structure entry Y that references X (or from CR3 if X is in the root paging structure). With PAE paging, the PAT memory type for accesses to the PDPTEs is WB.

### 28.3.1 Information That May Be Cached

Section 4.10, "Caching Translation Information" in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A* identifies two kinds of translation-related information that may be cached by a logical processor: **translations**, which are mappings from linear page numbers to physical page frames, and **paging-structure caches**, which map the upper bits of a linear page number to information from the paging-structure entries used to translate linear addresses matching those upper bits.

The same kinds of information may be cached when VPIDs and EPT are in use. A logical processor may cache and use such information based on its function. Information with different functionality is identified as follows:

- **Linear mappings**.[1] There are two kinds:
  - Linear translations. Each of these is a mapping from a linear page number to the physical page frame to which it translates, along with information about access privileges and memory typing.
  - Linear paging-structure-cache entries. Each of these is a mapping from the upper portion of a linear address to the physical address of the paging structure used to translate the corresponding region of the linear-address space, along with information about access privileges. For example, bits 47:39 of a linear address would map to the address of the relevant page-directory-pointer table.

  Linear mappings do not contain information from any EPT paging structure.
- **Guest-physical mappings**.[2] There are two kinds:
  - Guest-physical translations. Each of these is a mapping from a guest-physical page number to the physical page frame to which it translates, along with information about access privileges and memory typing.
  - Guest-physical paging-structure-cache entries. Each of these is a mapping from the upper portion of a guest-physical address to the physical address of the EPT paging structure used to translate the corresponding region of the guest-physical address space, along with information about access privileges.

  The information in guest-physical mappings about access privileges and memory typing is derived from EPT paging structures.
- **Combined mappings**.[3] There are two kinds:
  - Combined translations. Each of these is a mapping from a linear page number to the physical page frame to which it translates, along with information about access privileges and memory typing.
  - Combined paging-structure-cache entries. Each of these is a mapping from the upper portion of a linear address to the physical address of the paging structure used to translate the corresponding region of the linear-address space, along with information about access privileges.

  The information in combined mappings about access privileges and memory typing is derived from both guest paging structures and EPT paging structures.

### 28.3.2 Creating and Using Cached Translation Information

The following items detail the creation of the mappings described in the previous section:[4]

- The following items describe the creation of mappings while EPT is not in use (including execution outside VMX non-root operation):
  - Linear mappings may be created. They are derived from the paging structures referenced (directly or indirectly) by the current value of CR3 and are associated with the current VPID and the current PCID.

1. Earlier versions of this manual used the term "VPID-tagged" to identify linear mappings.
2. Earlier versions of this manual used the term "EPTP-tagged" to identify guest-physical mappings.
3. Earlier versions of this manual used the term "dual-tagged" to identify combined mappings.
4. This section associated cached information with the current VPID and PCID. If PCIDs are not supported or are not being used (e.g., because CR4.PCIDE = 0), all the information is implicitly associated with PCID 000H; see Section 4.10.1, "Process-Context Identifiers (PCIDs)," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

  - No linear mappings are created with information derived from paging-structure entries that are not present (bit 0 is 0) or that set reserved bits. For example, if a PTE is not present, no linear mapping are created for any linear page number whose translation would use that PTE.
  - No guest-physical or combined mappings are created while EPT is not in use.
- The following items describe the creation of mappings while EPT is in use:
  - Guest-physical mappings may be created. They are derived from the EPT paging structures referenced (directly or indirectly) by bits 51:12 of the current EPTP. These 40 bits contain the address of the EPT-PML4-table. (the notation **EP4TA** refers to those 40 bits). Newly created guest-physical mappings are associated with the current EP4TA.
  - Combined mappings may be created. They are derived from the EPT paging structures referenced (directly or indirectly) by the current EP4TA. If CR0.PG = 1, they are also derived from the paging structures referenced (directly or indirectly) by the current value of CR3. They are associated with the current VPID, the current PCID, and the current EP4TA.[1] No combined paging-structure-cache entries are created if CR0.PG = 0.[2]
  - No guest-physical mappings or combined mappings are created with information derived from EPT paging-structure entries that are not present (bits 2:0 are all 0) or that are misconfigured (see Section 28.2.3.1).
  - No combined mappings are created with information derived from guest paging-structure entries that are not present or that set reserved bits.
  - No linear mappings are created while EPT is in use.

The following items detail the use of the various mappings:

- If EPT is not in use (e.g., when outside VMX non-root operation), a logical processor may use cached mappings as follows:
  - For accesses using linear addresses, it may use linear mappings associated with the current VPID and the current PCID. It may also use global TLB entries (linear mappings) associated with the current VPID and any PCID.
  - No guest-physical or combined mappings are used while EPT is not in use.
- If EPT is in use, a logical processor may use cached mappings as follows:
  - For accesses using linear addresses, it may use combined mappings associated with the current VPID, the current PCID, and the current EP4TA. It may also use global TLB entries (combined mappings) associated with the current VPID, the current EP4TA, and any PCID.
  - For accesses using guest-physical addresses, it may use guest-physical mappings associated with the current EP4TA.
  - No linear mappings are used while EPT is in use.

## 28.3.3 Invalidating Cached Translation Information

Software modifications of paging structures (including EPT paging structures) may result in inconsistencies between those structures and the mappings cached by a logical processor. Certain operations invalidate information cached by a logical processor and can be used to eliminate such inconsistencies.

### 28.3.3.1 Operations that Invalidate Cached Mappings

The following operations invalidate cached mappings as indicated:

1. At any given time, a logical processor may be caching combined mappings for a VPID and a PCID that are associated with different EP4TAs. Similarly, it may be caching combined mappings for an EP4TA that are associated with different VPIDs and PCIDs.
2. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG can be 0 in VMX non-root operation only if the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

- Operations that architecturally invalidate entries in the TLBs or paging-structure caches independent of VMX operation (e.g., the INVLPG and INVPCID instructions) invalidate linear mappings and combined mappings.[1] They are required to do so only for the current VPID (but, for combined mappings, all EP4TAs). Linear mappings for the current VPID are invalidated even if EPT is in use.[2] Combined mappings for the current VPID are invalidated even if EPT is not in use.[3]
- An EPT violation invalidates any guest-physical mappings (associated with the current EP4TA) that would be used to translate the guest-physical address that caused the EPT violation. If that guest-physical address was the translation of a linear address, the EPT violation also invalidates any combined mappings for that linear address associated with the current PCID, the current VPID and the current EP4TA.
- If the "enable VPID" VM-execution control is 0, VM entries and VM exits invalidate linear mappings and combined mappings associated with VPID 0000H (for all PCIDs). Combined mappings for VPID 0000H are invalidated for all EP4TAs.
- Execution of the INVVPID instruction invalidates linear mappings and combined mappings. Invalidation is based on instruction operands, called the INVVPID type and the INVVPID descriptor. Four INVVPID types are currently defined:
  - **Individual-address.** If the INVVPID type is 0, the logical processor invalidates linear mappings and combined mappings associated with the VPID specified in the INVVPID descriptor and that would be used to translate the linear address specified in of the INVVPID descriptor. Linear mappings and combined mappings for that VPID and linear address are invalidated for all PCIDs and, for combined mappings, all EP4TAs. (The instruction may also invalidate mappings associated with other VPIDs and for other linear addresses.)
  - **Single-context.** If the INVVPID type is 1, the logical processor invalidates all linear mappings and combined mappings associated with the VPID specified in the INVVPID descriptor. Linear mappings and combined mappings for that VPID are invalidated for all PCIDs and, for combined mappings, all EP4TAs. (The instruction may also invalidate mappings associated with other VPIDs.)
  - **All-context.** If the INVVPID type is 2, the logical processor invalidates linear mappings and combined mappings associated with all VPIDs except VPID 0000H and with all PCIDs. (The instruction may also invalidate linear mappings with VPID 0000H.) Combined mappings are invalidated for all EP4TAs.
  - **Single-context-retaining-globals.** If the INVVPID type is 3, the logical processor invalidates linear mappings and combined mappings associated with the VPID specified in the INVVPID descriptor. Linear mappings and combined mappings for that VPID are invalidated for all PCIDs and, for combined mappings, all EP4TAs. The logical processor is **not** required to invalidate information that was used for **global** translations (although it may do so). See Section 4.10, "Caching Translation Information" for details regarding global translations. (The instruction may also invalidate mappings associated with other VPIDs.)

  See Chapter 30 for details of the INVVPID instruction. See Section 28.3.3.3 for guidelines regarding use of this instruction.
- Execution of the INVEPT instruction invalidates guest-physical mappings and combined mappings. Invalidation is based on instruction operands, called the INVEPT type and the INVEPT descriptor. Two INVEPT types are currently defined:
  - **Single-context.** If the INVEPT type is 1, the logical processor invalidates all guest-physical mappings and combined mappings associated with the EP4TA specified in the INVEPT descriptor. Combined mappings for that EP4TA are invalidated for all VPIDs and all PCIDs. (The instruction may invalidate mappings associated with other EP4TAs.)
  - **All-context.** If the INVEPT type is 2, the logical processor invalidates guest-physical mappings and combined mappings associated with all EP4TAs (and, for combined mappings, for all VPIDs and PCIDs).

---

1. See Section 4.10.4, "Invalidation of TLBs and Paging-Structure Caches," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A* for an enumeration of operations that architecturally invalidate entries in the TLBs and paging-structure caches independent of VMX operation.
2. While no linear mappings are created while EPT is in use, a logical processor may retain, while EPT is in use, linear mappings (for the same VPID as the current one) there were created earlier, when EPT was not in use.
3. While no combined mappings are created while EPT is not in use, a logical processor may retain, while EPT is in not use, combined mappings (for the same VPID as the current one) there were created earlier, when EPT was in use.

See Chapter 30 for details of the INVEPT instruction. See Section 28.3.3.4 for guidelines regarding use of this instruction.

- A power-up or a reset invalidates all linear mappings, guest-physical mappings, and combined mappings.

### 28.3.3.2 Operations that Need Not Invalidate Cached Mappings

The following items detail cases of operations that are not required to invalidate certain cached mappings:

- Operations that architecturally invalidate entries in the TLBs or paging-structure caches independent of VMX operation are not required to invalidate any guest-physical mappings.
- The INVVPID instruction is not required to invalidate any guest-physical mappings.
- The INVEPT instruction is not required to invalidate any linear mappings.
- VMX transitions are not required to invalidate any guest-physical mappings. If the "enable VPID" VM-execution control is 1, VMX transitions are not required to invalidate any linear mappings or combined mappings.
- The VMXOFF and VMXON instructions are not required to invalidate any linear mappings, guest-physical mappings, or combined mappings.

A logical processor may invalidate any cached mappings at any time. For this reason, the operations identified above may invalidate the indicated mappings despite the fact that doing so is not required.

### 28.3.3.3 Guidelines for Use of the INVVPID Instruction

The need for VMM software to use the INVVPID instruction depends on how that software is virtualizing memory (e.g., see Section 32.3, "Memory Virtualization").

If EPT is not in use, it is likely that the VMM is virtualizing the guest paging structures. Such a VMM may configure the VMCS so that all or some of the operations that invalidate entries the TLBs and the paging-structure caches (e.g., the INVLPG instruction) cause VM exits. If VMM software is emulating these operations, it may be necessary to use the INVVPID instruction to ensure that the logical processor's TLBs and the paging-structure caches are appropriately invalidated.

Requirements of when software should use the INVVPID instruction depend on the specific algorithm being used for page-table virtualization. The following items provide guidelines for software developers:

- Emulation of the INVLPG instruction may require execution of the INVVPID instruction as follows:
  - The INVVPID type is individual-address (0).
  - The VPID in the INVVPID descriptor is the one assigned to the virtual processor whose execution is being emulated.
  - The linear address in the INVVPID descriptor is that of the operand of the INVLPG instruction being emulated.
- Some instructions invalidate all entries in the TLBs and paging-structure caches—except for global translations. An example is the MOV to CR3 instruction. (See Section 4.10, "Caching Translation Information" in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A* for details regarding global translations.) Emulation of such an instruction may require execution of the INVVPID instruction as follows:
  - The INVVPID type is single-context-retaining-globals (3).
  - The VPID in the INVVPID descriptor is the one assigned to the virtual processor whose execution is being emulated.
- Some instructions invalidate all entries in the TLBs and paging-structure caches—including for global translations. An example is the MOV to CR4 instruction if the value of value of bit 4 (page global enable—PGE) is changing. Emulation of such an instruction may require execution of the INVVPID instruction as follows:
  - The INVVPID type is single-context (1).
  - The VPID in the INVVPID descriptor is the one assigned to the virtual processor whose execution is being emulated.

If EPT is not in use, the logical processor associates all mappings it creates with the current VPID, and it will use such mappings to translate linear addresses. For that reason, a VMM should not use the same VPID for different

non-EPT guests that use different page tables. Doing so may result in one guest using translations that pertain to the other.

If EPT is in use, the instructions enumerated above might not be configured to cause VM exits and the VMM might not be emulating them. In that case, executions of the instructions by guest software properly invalidate the required entries in the TLBs and paging-structure caches (see Section 28.3.3.1); execution of the INVVPID instruction is not required.

If EPT is in use, the logical processor associates all mappings it creates with the value of bits 51:12 of current EPTP. If a VMM uses different EPTP values for different guests, it may use the same VPID for those guests. Doing so cannot result in one guest using translations that pertain to the other.

The following guidelines apply more generally and are appropriate even if EPT is in use:

- As detailed in Section 29.4.5, an access to the APIC-access page might not cause an APIC-access VM exit if software does not properly invalidate information that may be cached from the paging structures. If, at one time, the current VPID on a logical processor was a non-zero value X, it is recommended that software use the INVVPID instruction with the "single-context" INVVPID type and with VPID X in the INVVPID descriptor before a VM entry on the same logical processor that establishes VPID X and either (a) the "virtualize APIC accesses" VM-execution control was changed from 0 to 1; or (b) the value of the APIC-access address was changed.
- Software can use the INVVPID instruction with the "all-context" INVVPID type immediately after execution of the VMXON instruction or immediately prior to execution of the VMXOFF instruction. Either prevents potentially undesired retention of information cached from paging structures between separate uses of VMX operation.

### 28.3.3.4 Guidelines for Use of the INVEPT Instruction

The following items provide guidelines for use of the INVEPT instruction to invalidate information cached from the EPT paging structures.

- Software should use the INVEPT instruction with the "single-context" INVEPT type after making any of the following changes to an EPT paging-structure entry (the INVEPT descriptor should contain an EPTP value that references — directly or indirectly — the modified EPT paging structure):
  - Changing any of the privilege bits 2:0 from 1 to 0.
  - Changing the physical address in bits 51:12.
  - Clearing bit 8 (the accessed flag) if accessed and dirty flags for EPT will be enabled.
  - For an EPT PDPTE or an EPT PDE, changing bit 7 (which determines whether the entry maps a page).
  - For the **last** EPT paging-structure entry used to translate a guest-physical address (an EPT PDPTE with bit 7 set to 1, an EPT PDE with bit 7 set to 1, or an EPT PTE), changing either bits 5:3 or bit 6. (These bits determine the effective memory type of accesses using that EPT paging-structure entry; see Section 28.2.5.)
  - For the **last** EPT paging-structure entry used to translate a guest-physical address (an EPT PDPTE with bit 7 set to 1, an EPT PDE with bit 7 set to 1, or an EPT PTE), clearing bit 9 (the dirty flag) if accessed and dirty flags for EPT will be enabled.
- Software should use the INVEPT instruction with the "single-context" INVEPT type before a VM entry with an EPTP value X such that X[6] = 1 (accessed and dirty flags for EPT are enabled) if the logical processor had earlier been in VMX non-root operation with an EPTP value Y such that Y[6] = 0 (accessed and dirty flags for EPT are not enabled) and Y[51:12] = X[51:12].
- Software may use the INVEPT instruction after modifying a present EPT paging-structure entry to change any of the privilege bits 2:0 from 0 to 1. Failure to do so may cause an EPT violation that would not otherwise occur. Because an EPT violation invalidates any mappings that would be used by the access that caused the EPT violation (see Section 28.3.3.1), an EPT violation will not recur if the original access is performed again, even if the INVEPT instruction is not executed.
- Because a logical processor does not cache any information derived from EPT paging-structure entries that are not present or misconfigured (see Section 28.2.3.1), it is not necessary to execute INVEPT following modification of an EPT paging-structure entry that had been not present or misconfigured.
- As detailed in Section 29.4.5, an access to the APIC-access page might not cause an APIC-access VM exit if software does not properly invalidate information that may be cached from the EPT paging structures. If EPT

was in use on a logical processor at one time with EPTP X, it is recommended that software use the INVEPT instruction with the "single-context" INVEPT type and with EPTP X in the INVEPT descriptor before a VM entry on the same logical processor that enables EPT with EPTP X and either (a) the "virtualize APIC accesses" VM-execution control was changed from 0 to 1; or (b) the value of the APIC-access address was changed.

- Software can use the INVEPT instruction with the "all-context" INVEPT type immediately after execution of the VMXON instruction or immediately prior to execution of the VMXOFF instruction. Either prevents potentially undesired retention of information cached from EPT paging structures between separate uses of VMX operation.

In a system containing more than one logical processor, software must account for the fact that information from an EPT paging-structure entry may be cached on logical processors other than the one that modifies that entry. The process of propagating the changes to a paging-structure entry is commonly referred to as "TLB shootdown." A discussion of TLB shootdown appears in Section 4.10.5, "Propagation of Paging-Structure Changes to Multiple Processors," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

# CHAPTER 29
# APIC VIRTUALIZATION AND VIRTUAL INTERRUPTS

The VMCS includes controls that enable the virtualization of interrupts and the Advanced Programmable Interrupt Controller (APIC).

When these controls are used, the processor will emulate many accesses to the APIC, track the state of the virtual APIC, and deliver virtual interrupts — all in VMX non-root operation with out a VM exit.[1]

The processor tracks the state of the virtual APIC using a virtual-APIC page identified by the virtual-machine monitor (VMM). Section 29.1 discusses the virtual-APIC page and how the processor uses it to track the state of the virtual APIC.

The following are the VM-execution controls relevant to APIC virtualization and virtual interrupts (see Section 24.6 for information about the locations of these controls):

- **Virtual-interrupt delivery.** This controls enables the evaluation and delivery of pending virtual interrupts (Section 29.2). It also enables the emulation of writes (memory-mapped or MSR-based, as enabled) to the APIC registers that control interrupt prioritization.
- **Use TPR shadow.** This control enables emulation of accesses to the APIC's task-priority register (TPR) via CR8 (Section 29.3) and, if enabled, via the memory-mapped or MSR-based interfaces.
- **Virtualize APIC accesses.** This control enables virtualization of memory-mapped accesses to the APIC (Section 29.4) by causing VM exits on accesses to a VMM-specified APIC-access page. Some of the other controls, if set, may cause some of these accesses to be emulated rather than causing VM exits.
- **Virtualize x2APIC mode.** This control enables virtualization of MSR-based accesses to the APIC (Section 29.5).
- **APIC-register virtualization.** This control allows memory-mapped and MSR-based reads of most APIC registers (as enabled) by satisfying them from the virtual-APIC page. It directs memory-mapped writes to the APIC-access page to the virtual-APIC page, following them by VM exits for VMM emulation.
- **Process posted interrupts.** This control allows software to post virtual interrupts in a data structure and send a notification to another logical processor; upon receipt of the notification, the target processor will process the posted interrupts by copying them into the virtual-APIC page (Section 29.6).

"Virtualize APIC accesses", "virtualize x2APIC mode", "virtual-interrupt delivery", and "APIC-register virtualization" are all secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, the processor operates as if these controls were all 0. See Section 24.6.2.

## 29.1 VIRTUAL APIC STATE

The **virtual-APIC page** is a 4-KByte region of memory that the processor uses the virtual-APIC page to virtualize certain accesses to APIC registers and to manage virtual interrupts. The physical address of the virtual-APIC page is the **virtual-APIC address**, a 64-bit VM-execution control field in the VMCS (see Section 24.6.8).

Depending on the settings of certain VM-execution controls, the processor may virtualize certain fields on the virtual-APIC page with functionality analogous to that performed by the local APIC. Section 29.1.1 identifies and defines these fields. Section 29.1.2, Section 29.1.3, Section 29.1.4, and Section 29.1.5 detail the actions taken to virtualize updates to some of these fields.

### 29.1.1 Virtualized APIC Registers

Depending on the setting of certain VM-execution controls, a logical processor may virtualize certain accesses to APIC registers using the following fields on the virtual-APIC page:

- **Virtual task-priority register (VTPR)**: the 32-bit field located at offset 080H on the virtual-APIC page.

1. In most cases, it is not necessary for a virtual-machine monitor (VMM) to inject virtual interrupts as part of VM entry.

- **Virtual processor-priority register (VPPR)**: the 32-bit field located at offset 0A0H on the virtual-APIC page.
- **Virtual end-of-interrupt register (VEOI)**: the 32-bit field located at offset 0B0H on the virtual-APIC page.
- **Virtual interrupt-service register (VISR)**: the 256-bit value comprising eight non-contiguous 32-bit fields at offsets 100H, 110H, 120H, 130H, 140H, 150H, 160H, and 170H on the virtual-APIC page. Bit x of the VISR is at bit position (x & 1FH) at offset (100H | ((x & E0H) » 1)). The processor uses only the low 4 bytes of each of the 16-byte fields at offsets 100H, 110H, 120H, 130H, 140H, 150H, 160H, and 170H.
- **Virtual interrupt-request register (VIRR)**: the 256-bit value comprising eight non-contiguous 32-bit fields at offsets 200H, 210H, 220H, 230H, 240H, 250H, 260H, and 270H on the virtual-APIC page. Bit x of the VIRR is at bit position (x & 1FH) at offset (200H | ((x & E0H) » 1)). The processor uses only the low 4 bytes of each of the 16-Byte fields at offsets 200H, 210H, 220H, 230H, 240H, 250H, 260H, and 270H.
- **Virtual interrupt-command register (VICR_LO)**: the 32-bit field located at offset 300H on the virtual-APIC page
- **Virtual interrupt-command register (VICR_HI)**: the 32-bit field located at offset 310H on the virtual-APIC page.

### 29.1.2 TPR Virtualization

The processor performs **TPR virtualization** in response to the following operations: (1) virtualization of the MOV to CR8 instruction; (2) virtualization of a write to offset 080H on the APIC-access page; and (3) virtualization of the WRMSR instruction with ECX = 808H. See Section 29.3, Section 29.4.3, and Section 29.5 for details of when TPR virtualization is performed.

The following pseudocode details the behavior of TPR virtualization:

```
IF "virtual-interrupt delivery" is 0
    THEN
        IF VTPR[7:4] < TPR threshold (see Section 24.6.8)
            THEN cause VM exit due to TPR below threshold;
        FI;
    ELSE
        perform PPR virtualization (see Section 29.1.3);
        evaluate pending virtual interrupts (see Section 29.2.1);
FI;
```

Any VM exit caused by TPR virtualization is trap-like: the instruction causing TPR virtualization completes before the VM exit occurs (for example, the value of CS:RIP saved in the guest-state area of the VMCS references the next instruction).

### 29.1.3 PPR Virtualization

The processor performs **PPR virtualization** in response to the following operations: (1) VM entry; (2) TPR virtualization; and (3) EOI virtualization. See Section 26.3.2.5, Section 29.1.2, and Section 29.1.4 for details of when PPR virtualization is performed.

PPR virtualization uses the guest interrupt status (specifically, SVI; see Section 24.4.2) and VTPR.The following pseudocode details the behavior of PPR virtualization:

```
IF VTPR[7:4] ≥ SVI[7:4]
    THEN VPPR ← VTPR & FFH;
    ELSE VPPR ← SVI & F0H;
FI;
```

PPR virtualization always clears bytes 3:1 of VPPR.

PPR virtualization is caused only by TPR virtualization, EOI virtualization, and VM entry. Delivery of a virtual interrupt also modifies VPPR, but in a different way (see Section 29.2.2). No other operations modify VPPR, even if they modify SVI, VISR, or VTPR.

### 29.1.4 EOI Virtualization

The processor performs **EOI virtualization** in response to the following operations: (1) virtualization of a write to offset 0B0H on the APIC-access page; and (2) virtualization of the WRMSR instruction with ECX = 80BH. See Section 29.4.3 and Section 29.5 for details of when EOI virtualization is performed. EOI virtualization occurs only if the "virtual-interrupt delivery" VM-execution control is 1.

EOI virtualization uses and updates the guest interrupt status (specifically, SVI; see Section 24.4.2). The following pseudocode details the behavior of EOI virtualization:

```
Vector ← SVI;
VISR[Vector] ← 0; (see Section 29.1.1 for definition of VISR)
IF any bits set in VISR
    THEN SVI ← highest index of bit set in VISR
    ELSE SVI ← 0;
FI;
perform PPR virtualiation (see Section 29.1.3);
IF EOI_exit_bitmap[Vector] = 1 (see Section 24.6.8 for definition of EOI_exit_bitmap)
    THEN cause EOI-induced VM exit with Vector as exit qualification;
    ELSE evaluate pending virtual interrupts; (see Section 29.2.1)
FI;
```

Any VM exit caused by EOI virtualization is trap-like: the instruction causing EOI virtualization completes before the VM exit occurs (for example, the value of CS:RIP saved in the guest-state area of the VMCS references the next instruction).

### 29.1.5 Self-IPI Virtualization

The processor performs **self-IPI virtualization** in response to the following operations: (1) virtualization of a write to offset 300H on the APIC-access page; and (2) virtualization of the WRMSR instruction with ECX = 83FH. See Section 29.4.3 and Section 29.5 for details of when self-IPI virtualization is performed. Self-IPI virtualization occurs only if the "virtual-interrupt delivery" VM-execution control is 1.

Each operation that leads to self-IPI virtualization provides an 8-bit vector (see Section 29.4.3 and Section 29.5). Self-IPI virtualization updates the guest interrupt status (specifically, RVI; see Section 24.4.2). The following pseudocode details the behavior of self-IPI virtualization:

```
VIRR[Vector] ← 1; (see Section 29.1.1 for definition of VIRR)
RVI ← max{RVI,Vector};
evaluate pending virtual interrupts; (see Section 29.2.1)
```

## 29.2 EVALUATION AND DELIVERY OF VIRTUAL INTERRUPTS

If the "virtual-interrupt delivery" VM-execution control is 1, certain actions in VMX non-root operation or during VM entry cause the processor to evaluate and deliver virtual interrupts.

Evaluation of virtual interrupts is triggered by certain actions change the state of the virtual-APIC page and is described in Section 29.2.1. This evaluation may result in recognition of a virtual interrupt. Once a virtual interrupt is recognized, the processor may deliver it within VMX non-root operation without a VM exit. Virtual-interrupt delivery is described in Section 29.2.2.

### 29.2.1 Evaluation of Pending Virtual Interrupts

If the "virtual-interrupt delivery" VM-execution control is 1, certain actions cause a logical processor to **evaluate pending virtual interrupts**.

The following actions cause the evaluation of pending virtual interrupts: VM entry; TPR virtualization; EOI virtualization; self-IPI virtualization; and posted-interrupt processing. See Section 26.3.2.5, Section 29.1.2, Section

29.1.4, Section 29.1.5, and Section 29.6 for details of when evaluation of pending virtual interrupts is performed. No other operations cause the evaluation of pending virtual interrupts, even if they modify RVI or VPPR.

Evaluation of pending virtual interrupts uses the guest interrupt status (specifically, RVI; see Section 24.4.2). The following pseudocode details the evaluation of pending virtual interrupts:

```
IF "interrupt-window exiting" is 0 AND
RVI[7:4] > VPPR[7:4] (see Section 29.1.1 for definition of VPPR)
        THEN recognize a pending virtual interrupt;
    ELSE
        do not recognize a pending virtual interrupt;
FI;
```

Once recognized, a virtual interrupt may be delivered in VMX non-root operation; see Section 29.2.2.

Evaluation of pending virtual interrupts is caused only by VM entry, TPR virtualization, EOI virtualization, self-IPI virtualization, and posted-interrupt processing. No other operations do so, even if they modify RVI or VPPR. The logical processor ceases recognition of a pending virtual interrupt following the delivery of a virtual interrupt.

### 29.2.2 Virtual-Interrupt Delivery

If a virtual interrupt has been recognized (see Section 29.2.1), it will be delivered at an instruction boundary when the following conditions all hold: (1) RFLAGS.IF = 1; (2) there is no blocking by STI; (3) there is no blocking by MOV SS or by POP SS; and (4) the "interrupt-window exiting" VM-execution control is 0.

Virtual-interrupt delivery has the same priority as that of VM exits due to the 1-setting of the "interrupt-window exiting" VM-execution control.[1] Thus, non-maskable interrupts (NMIs) and higher priority events take priority over delivery of a virtual interrupt; delivery of a virtual interrupt takes priority over external interrupts and lower priority events.

Virtual-interrupt delivery wakes a logical processor from the same inactive activity states as would an external interrupt. Specifically, it wakes a logical processor from the states entered using the HLT and MWAIT instructions. It does not wake a logical processor in the shutdown state or in the wait-for-SIPI state.

Virtual-interrupt delivery updates the guest interrupt status (both RVI and SVI; see Section 24.4.2) and delivers an event within VMX non-root operation without a VM exit. The following pseudocode details the behavior of virtual-interrupt delivery (see Section 29.1.1 for definition of VISR, VIRR, and VPPR):

```
Vector ← RVI;
VISR[Vector] ← 1;
SVI ← Vector;
VPPR ← Vector & F0H;
VIRR[Vector] ← 0;
IF any bits set in VIRR
    THEN RVI ← highest index of bit set in VIRR
    ELSE RVI ← 0;
FI;
deliver interrupt with Vector through IDT;
cease recognition of any pending virtual interrupt;
```

## 29.3 VIRTUALIZING CR8-BASED TPR ACCESSES

In 64-bit mode, software can access the local APIC's task-priority register (TPR) through CR8. Specifically, software uses the MOV from CR8 and MOV to CR8 instructions (see Section 10.8.6, "Task Priority in IA-32e Mode"). This section describes how these accesses can be virtualized.

1. A logical processor never recognizes or delivers a virtual interrupt if the "interrupt-window exiting" VM-execution control is 1. Because of this, the relative priority of virtual-interrupt delivery and VM exits due to the 1-setting of that control is not defined.

A virtual-machine monitor can virtualize these CR8-based APIC accesses by setting the "CR8-load exiting" and "CR8-store exiting" VM-execution controls, ensuring that the accesses cause VM exits (see Section 25.1.3). Alternatively, there are methods for virtualizing some CR8-based APIC accesses without VM exits.

Normally, an execution of MOV from CR8 or MOV to CR8 that does not fault or cause a VM exit accesses the APIC's TPR. However, such an execution are treated specially if the "use TPR shadow" VM-execution control is 1. The following items provide details:

- **MOV from CR8.** The instruction loads bits 3:0 of its destination operand with bits 7:4 of VTPR (see Section 29.1.1). Bits 63:4 of the destination operand are cleared.
- **MOV to CR8.** The instruction stores bits 3:0 of its source operand into bits 7:4 of VTPR; the remainder of VTPR (bits 3:0 and bits 31:8) are cleared. Following this, the processor performs TPR virtualization (see Section 29.1.2).

## 29.4 VIRTUALIZING MEMORY-MAPPED APIC ACCESSES

When the local APIC is in xAPIC mode, software accesses the local APIC's control registers using a memory-mapped interface. Specifically, software uses linear addresses that translate to physical addresses on page frame indicated by the base address in the IA32_APIC_BASE MSR (see Section 10.4.4, "Local APIC Status and Location"). This section describes how these accesses can be virtualized.

A virtual-machine monitor (VMM) can virtualize these memory-mapped APIC accesses by ensuring that any access to a linear address that would access the local APIC instead causes a VM exit. This could be done using paging or the extended page-table mechanism (EPT). Another way is by using the 1-setting of the "virtualize APIC accesses" VM-execution control.

If the "virtualize APIC accesses" VM-execution control is 1, the logical processor treats specially memory accesses using linear addresses that translate to physical addresses in the 4-KByte **APIC-access page**.[1] (The APIC-access page is identified by the **APIC-access address**, a field in the VMCS; see Section 24.6.8.)

In general, an access to the APIC-access page causes an **APIC-access VM exit**. APIC-access VM exits provide a VMM with information about the access causing the VM exit. Section 29.4.1 discusses the priority of APIC-access VM exits.

Certain VM-execution controls enable the processor to virtualize certain accesses to the APIC-access page without a VM exit. In general, this virtualization causes these accesses to be made to the virtual-APIC page instead of the APIC-access page.

### NOTES

Unless stated otherwise, this section characterizes only linear accesses to the APIC-access page; an access to the APIC-access page is a linear access if (1) it results from a memory access using a linear address; and (2) the access's physical address is the translation of that linear address. Section 29.4.6 discusses accesses to the APIC-access page that are not linear accesses.

The distinction between the APIC-access page and the virtual-APIC page allows a VMM to share paging structures or EPT paging structures among the virtual processors of a virtual machine (the shared paging structures referencing the same APIC-access address, which appears in the VMCS of all the virtual processors) while giving each virtual processor its own virtual APIC (the VMCS of each virtual processor will have a unique virtual-APIC address).

Section 29.4.2 discusses when and how the processor may virtualize read accesses from the APIC-access page. Section 29.4.3 does the same for write accesses. When virtualizing a write to the APIC-access page, the processor typically takes actions in addition to passing the write through to the virtual-APIC page.

1. Even when addresses are translated using EPT (see Section 28.2), the determination of whether an APIC-access VM exit occurs depends on an access's physical address, not its guest-physical address. Even when CR0.PG = 0, ordinary memory accesses by software use linear addresses; the fact that CR0.PG = 0 means only that the identity translation is used to convert linear addresses to physical (or guest-physical) addresses.

The discussion in those sections uses the concept of an **operation** within which these memory accesses may occur. For those discussions, an "operation" can be an iteration of a REP-prefixed string instruction, an execution of any other instruction, or delivery of an event through the IDT.

The 1-setting of the "virtualize APIC accesses" VM-execution control may also affect accesses to the APIC-access page that do not result directly from linear addresses. This is discussed in Section 29.4.6.

### 29.4.1 Priority of APIC-Access VM Exits

The following items specify the priority of APIC-access VM exits relative to other events.

- The priority of an APIC-access VM exit due to a memory access is below that of any page fault or EPT violation that that access may incur. That is, an access does not cause an APIC-access VM exit if it would cause a page fault or an EPT violation.
- A memory access does not cause an APIC-access VM exit until after the accessed flags are set in the paging structures (including EPT paging structures, if enabled).
- A write access does not cause an APIC-access VM exit until after the dirty flags are set in the appropriate paging structure and EPT paging structure (if enabled).
- With respect to all other events, any APIC-access VM exit due to a memory access has the same priority as any page fault or EPT violation that the access could cause. (This item applies to other events that the access may generate as well as events that may be generated by other accesses by the same operation.)

These principles imply, among other things, that an APIC-access VM exit may occur during the execution of a repeated string instruction (including INS and OUTS). Suppose, for example, that the first *n* iterations (*n* may be 0) of such an instruction do not access the APIC-access page and that the next iteration does access that page. As a result, the first *n* iterations may complete and be followed by an APIC-access VM exit. The instruction pointer saved in the VMCS references the repeated string instruction and the values of the general-purpose registers reflect the completion of *n* iterations.

### 29.4.2 Virtualizing Reads from the APIC-Access Page

A read access from the APIC-access page causes an APIC-access VM exit if any of the following are true:

- The "use TPR shadow" VM-execution control is 0.
- The access is for an instruction fetch.
- The access is more than 32 bits in size.
- The access is part of an operation for which the processor has already virtualized a write to the APIC-access page.
- The access is not entirely contained within the low 4 bytes of a naturally aligned 16-byte region. That is, bits 3:2 of the access's address are 0, and the same is true of the address of the highest byte accessed.

If none of the above are true, whether a read access is virtualized depends on the setting of the "APIC-register virtualization" VM-execution control:

- If "APIC-register virtualization" is 0, a read access is virtualized if its page offset is 080H (task priority); otherwise, the access causes an APIC-access VM exit.
- If "APIC-register virtualization is 1, a read access is virtualized if it is entirely within one the following ranges of offsets:
  - 020H–023H (local APIC ID);
  - 030H–033H (local APIC version);
  - 080H–083H (task priority);
  - 0B0H–0B3H (end of interrupt);
  - 0D0H–0D3H (logical destination);
  - 0E0H–0E3H (destination format);

— 0F0H–0F3H (spurious-interrupt vector);

— 100H–103H, 110H–113H, 120H–123H, 130H–133H, 140H–143H, 150H–153H, 160H–163H, or 170H–173H (in-service);

— 180H–183H, 190H–193H, 1A0H–1A3H, 1B0H–1B3H, 1C0H–1C3H, 1D0H–1D3H, 1E0H–1E3H, or 1F0H–1F3H (trigger mode);

— 200H–203H, 210H–213H, 220H–223H, 230H–233H, 240H–243H, 250H–253H, 260H–263H, or 270H–273H (interrupt request);

— 280H–283H (error status);

— 300H–303H or 310H–313H (interrupt command);

— 320H–323H, 330H–333H, 340H–343H, 350H–353H, 360H–363H, or 370H–373H (LVT entries);

— 380H–383H (initial count); or

— 3E0H–3E3H (divide configuration).

In all other cases, the access causes an APIC-access VM exit.

A read access from the APIC-access page that is virtualized returns data from the corresponding page offset on the virtual-APIC page.[1]

## 29.4.3 Virtualizing Writes to the APIC-Access Page

Whether a write access to the APIC-access page is virtualized depends on the settings of the VM-execution controls and the page offset of the access. Section 29.4.3.1 details when APIC-write virtualization occurs.

Unlike reads, writes to the local APIC have side effects; because of this, virtualization of writes to the APIC-access page may require emulation specific to the access's page offset (which identifies the APIC register being accessed). Section 29.4.3.2 describes this **APIC-write emulation**.

For some page offsets, it is necessary for software to complete the virtualization after a write completes. In these cases, the processor causes an **APIC-write VM exit** to invoke VMM software. Section 29.4.3.3 discusses APIC-write VM exits.

### 29.4.3.1 Determining Whether a Write Access is Virtualized

A write access to the APIC-access page causes an APIC-access VM exit if any of the following are true:

- The "use TPR shadow" VM-execution control is 0.
- The access is more than 32 bits in size.
- The access is part of an operation for which the processor has already virtualized a write (with a different page offset or a different size) to the APIC-access page.
- The access is not entirely contained within the low 4 bytes of a naturally aligned 16-byte region. That is, bits 3:2 of the access's address are 0, and the same is true of the address of the highest byte accessed.

If none of the above are true, whether a write access is virtualized depends on the settings of the "APIC-register virtualization" and "virtual-interrupt delivery" VM-execution controls:

- If the "APIC-register virtualization" and "virtual-interrupt delivery" VM-execution controls are both 0, a write access is virtualized if its page offset is 080H; otherwise, the access causes an APIC-access VM exit.
- If the "APIC-register virtualization" VM-execution control is 0 and the "virtual-interrupt delivery" VM-execution control is 1, a write access is virtualized if its page offset is 080H (task priority), 0B0H (end of interrupt), and 300H (interrupt command — low); otherwise, the access causes an APIC-access VM exit.
- If "APIC-register virtualization is 1, a write access is virtualized if it is entirely within one the following ranges of offsets:

1. The memory type used for accesses that read from the virtual-APIC page is reported in bits 53:50 of the IA32_VMX_BASIC MSR (see Appendix A.1).

— 020H–023H (local APIC ID);
— 080H–083H (task priority);
— 0B0H–0B3H (end of interrupt);
— 0D0H–0D3H (logical destination);
— 0E0H–0E3H (destination format);
— 0F0H–0F3H (spurious-interrupt vector);
— 280H–283H (error status);
— 300H–303H or 310H–313H (interrupt command);
— 320H–323H, 330H–333H, 340H–343H, 350H–353H, 360H–363H, or 370H–373H (LVT entries);
— 380H–383H (initial count); or
— 3E0H–3E3H (divide configuration).

In all other cases, the access causes an APIC-access VM exit.

The processor virtualizes a write access to the APIC-access page by writing data to the corresponding page offset on the virtual-APIC page.[1] Following this, the processor performs certain actions after completion of the operation of which the access was a part.[2] APIC-write emulation is described in Section 29.4.3.2.

### 29.4.3.2 APIC-Write Emulation

If the processor virtualizes a write access to the APIC-access page, it performs additional actions after completion of an operation of which the access was a part. These actions are called **APIC-write emulation**.

The details of APIC-write emulation depend upon the page offset of the virtualized write access:[3]

- 080H (task priority). The processor clears bytes 3:1 of VTPR and then causes TPR virtualization (Section 29.1.2).
- 0B0H (end of interrupt). If the "virtual-interrupt delivery" VM-execution control is 1, the processor clears VEOI and then causes EOI virtualization (Section 29.1.4); otherwise, the processor causes an APIC-write VM exit (Section 29.4.3.3).
- 300H (interrupt command — low). If the "virtual-interrupt delivery" VM-execution control is 1, the processor checks the value of VICR_LO to determine whether the following are all true:
  — Reserved bits (31:20, 17:16, 13) and bit 12 (delivery status) are all 0.
  — Bits 19:18 (destination shorthand) are 01B (self).
  — Bit 15 (trigger mode) is 0 (edge).
  — Bits 10:8 (delivery mode) are 000B (fixed).
  — Bits 7:4 (the upper half of the vector) are **not** 0000B.

  If all of the items above are true, the processor performs self-IPI virtualization using the 8-bit vector in byte 0 of VICR_LO (Section 29.1.5).

  If the "virtual-interrupt delivery" VM-execution control is 0, or if any of the items above are false, the processor causes an APIC-write VM exit (Section 29.4.3.3).
- 310H–313H (interrupt command — high). The processor clears bytes 2:0 of VICR_HI. No other virtualization or VM exit occurs.
- Any other page offset. The processor causes an APIC-write VM exit (Section 29.4.3.3).

1. The memory type used for accesses that write to the virtual-APIC page is reported in bits 53:50 of the IA32_VMX_BASIC MSR (see Appendix A.1).
2. Recall that, for the purposes of this discussion, an operation is an iteration of a REP-prefixed string instruction, an execution of any other instruction, or delivery of an event through the IDT.
3. For any operation, there can be only one page offset for which a write access was virtualized. This is because a write access is not virtualized if the processor has already virtualized a write access for the same operation with a different page offset.

APIC-write emulation takes priority over system-management interrupts (SMIs), INIT signals, and lower priority events. APIC-write emulation is not blocked if RFLAGS.IF = 0 or by the MOV SS, POP SS, or STI instructions.

If an operation causes a fault after a write access to the APIC-access page and before APIC-write emulation. In this case, APIC-write emulation occurs after the fault is delivered and before the fault handler can execute. However, if the operation causes a VM exit (perhaps due to a fault), the APIC-write emulation does not occur.

#### 29.4.3.3 APIC-Write VM Exits

In certain cases, VMM software must be invoked to complete the virtualization of a write access to the APIC-access page. In this case, APIC-write emulation causes an **APIC-write VM exit**. (Section 29.4.3.2 details the cases that causes APIC-write VM exits.)

APIC-write VM exits are invoked by APIC-write emulation, and APIC-write emulation occurs after an operation that performs a write access to the APIC-access page. Because of this, every APIC-write VM exit is trap-like: it occurs after completion of the operation containing the write access that caused the VM exit (for example, the value of CS:RIP saved in the guest-state area of the VMCS references the next instruction).

The basic exit reason for an APIC-write VM exit is "APIC write." The exit qualification is the page offset of the write access that led to the VM exit.

As noted in Section 29.5, execution of WRMSR with ECX = 83FH (self-IPI MSR) can lead to an APIC-write VM exit if the "virtual-interrupt delivery" VM-execution control is 1. The exit qualification for such an APIC-write VM exit is 3F0H.

### 29.4.4 Instruction-Specific Considerations

Certain instructions that use linear address may cause page faults even though they do not use those addresses to access memory. The APIC-virtualization features may affect these instructions as well:

- **CLFLUSH.** With regard to faulting, the processor operates as if CLFLUSH reads from the linear address in its source operand. If that address translates to one on the APIC-access page, the instruction may cause an APIC-access VM exit. If it does not, it will flush the corresponding cache line on the virtual-APIC page instead of the APIC-access page.
- **ENTER.** With regard to faulting, the processor operates if ENTER writes to the byte referenced by the final value of the stack pointer (even though it does not if its size operand is non-zero). If that value translates to an address on the APIC-access page, the instruction may cause an APIC-access VM exit. If it does not, it will cause the APIC-write emulation appropriate to the address's page offset.
- **MASKMOVQ and MAKSMOVDQU.** Even if the instruction's mask is zero, the processor may operate with regard to faulting as if MASKMOVQ or MASKMOVDQU writes to memory (the behavior is implementation-specific). In such a situation, an APIC-access VM exit may occur.
- **MONITOR.** With regard to faulting, the processor operates as if MONITOR reads from the effective address in RAX. If the resulting linear address translates to one on the APIC-access page, the instruction may cause an APIC-access VM exit.[1] If it does not, it will monitor the corresponding address on the virtual-APIC page instead of the APIC-access page.
- **PREFETCH.** An execution of the PREFETCH instruction that would result in an access to the APIC-access page does not cause an APIC-access VM exit. Such an access may prefetch data; if so, it is from the corresponding address on the virtual-APIC page.

Virtualization of accesses to the APIC-access page is principally intended for basic instructions such as AND, MOV, OR, TEST, XCHG, and XOR. Use of instructions that normally operate on floating-point, SSE, or AVX registers may cause APIC-access VM exit unconditionally regardless of the page offset they access on the APIC-access page.

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For IA-32 processors, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.

### 29.4.5 Issues Pertaining to Page Size and TLB Management

The 1-setting of the "virtualize APIC accesses" VM-execution is guaranteed to apply only if translations to the APIC-access address use a 4-KByte page. The following items provide details:

- If EPT is not in use, any linear address that translates to an address on the APIC-access page should use a 4-KByte page. Any access to a linear address that translates to the APIC-access page using a larger page may operate as if the "virtualize APIC accesses" VM-execution control were 0.
- If EPT is in use, any guest-physical address that translates to an address on the APIC-access page should use a 4-KByte page. Any access to a linear address that translates to a guest-physical address that in turn translates to the APIC-access page using a larger page may operate as if the "virtualize APIC accesses" VM-execution control were 0. (This is true also for guest-physical accesses to the APIC-access page; see Section 29.4.6.1.)

In addition, software should perform appropriate TLB invalidation when making changes that may affect APIC-virtualization. The specifics depend on whether VPIDs or EPT is being used:

- **VPIDs being used but EPT not being used.** Suppose that there is a VPID that has been used before and that software has since made either of the following changes: (1) set the "virtualize APIC accesses" VM-execution control when it had previously been 0; or (2) changed the paging structures so that some linear address translates to the APIC-access address when it previously did not. In that case, software should execute INVVPID (see "INVVPID— Invalidate Translations Based on VPID" in Section 30.3) before performing on the same logical processor and with the same VPID.[1]
- **EPT being used.** Suppose that there is an EPTP value that has been used before and that software has since made either of the following changes: (1) set the "virtualize APIC accesses" VM-execution control when it had previously been 0; or (2) changed the EPT paging structures so that some guest-physical address translates to the APIC-access address when it previously did not. In that case, software should execute INVEPT (see "INVEPT— Invalidate Translations Derived from EPT" in Section 30.3) before performing on the same logical processor and with the same EPTP value.[2]
- **Neither VPIDs nor EPT being used.** No invalidation is required.

Failure to perform the appropriate TLB invalidation may result in the logical processor operating as if the "virtualize APIC accesses" VM-execution control were 0 in responses to accesses to the affected address. (No invalidation is necessary if neither VPIDs nor EPT is being used.)

### 29.4.6 APIC Accesses Not Directly Resulting From Linear Addresses

Section 29.4 has described the treatment of accesses that use linear addresses that translate to addresses on the APIC-access page. This section considers memory accesses that do not result directly from linear addresses.

- An access is called a **guest-physical access** if (1) CR0.PG = 1;[3] (2) the "enable EPT" VM-execution control is 1;[4] (3) the access's physical address is the result of an EPT translation; and (4) either (a) the access was not generated by a linear address; or (b) the access's guest-physical address is not the translation of the access's linear address. Section 29.4.6.1 discusses the treatment of guest-physical accesses to the APIC-access page.
- An access is called a **physical access** if (1) either (a) the "enable EPT" VM-execution control is 0; or (b) the access's physical address is not the result of a translation through the EPT paging structures; and (2) either (a) the access is not generated by a linear address; or (b) the access's physical address is not the translation of its linear address. Section 29.4.6.2 discusses the treatment of physical accesses to the APIC-access page.

---

1. INVVPID should use either (1) the all-contexts INVVPID type; (2) the single-context INVVPID type with the VPID in the INVVPID descriptor; or (3) the individual-address INVVPID type with the linear address and the VPID in the INVVPID descriptor.
2. INVEPT should use either (1) the global INVEPT type; or (2) the single-context INVEPT type with the EPTP value in the INVEPT descriptor.
3. If the capability MSR IA32_VMX_CR0_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG must be 1 unless the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
4. "Enable EPT" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the "enable EPT" VM-execution control were 0. See Section 24.6.2.

#### 29.4.6.1 Guest-Physical Accesses to the APIC-Access Page

Guest-physical accesses include the following when guest-physical addresses are being translated using EPT:

- Reads from the guest paging structures when translating a linear address (such an access uses a guest-physical address that is not the translation of that linear address).
- Loads of the page-directory-pointer-table entries by MOV to CR when the logical processor is using (or that causes the logical processor to use) PAE paging (see Section 4.4).
- Updates to the accessed and dirty flags in the guest paging structures when using a linear address (such an access uses a guest-physical address that is not the translation of that linear address).

Every guest-physical access to an address on the APIC-access page causes an APIC-access VM exit. Such accesses are never virtualized regardless of the page offset.

The following items specify the priority relative to other events of APIC-access VM exits caused by guest-physical accesses to the APIC-access page.

- The priority of an APIC-access VM exit caused by a guest-physical access to memory is below that of any EPT violation that that access may incur. That is, a guest-physical access does not cause an APIC-access VM exit if it would cause an EPT violation.
- With respect to all other events, any APIC-access VM exit caused by a guest-physical access has the same priority as any EPT violation that the guest-physical access could cause.

#### 29.4.6.2 Physical Accesses to the APIC-Access Page

Physical accesses include the following:

- If the "enable EPT" VM-execution control is 0:
  - Reads from the paging structures when translating a linear address.
  - Loads of the page-directory-pointer-table entries by MOV to CR when the logical processor is using (or that causes the logical processor to use) PAE paging (see Section 4.4).
  - Updates to the accessed and dirty flags in the paging structures.
- If the "enable EPT" VM-execution control is 1, accesses to the EPT paging structures (including updates to the accessed and dirty flags for EPT).
- Any of the following accesses made by the processor to support VMX non-root operation:
  - Accesses to the VMCS region.
  - Accesses to data structures referenced (directly or indirectly) by physical addresses in VM-execution control fields in the VMCS. These include the I/O bitmaps, the MSR bitmaps, and the virtual-APIC page.
- Accesses that effect transitions into and out of SMM.[1] These include the following:
  - Accesses to SMRAM during SMI delivery and during execution of RSM.
  - Accesses during SMM VM exits (including accesses to MSEG) and during VM entries that return from SMM.

A physical access to the APIC-access page may or may not cause an APIC-access VM exit. If it does not cause an APIC-access VM exit, it may access the APIC-access page or the virtual-APIC page. Physical write accesses to the APIC-access page may or may not cause APIC-write emulation or APIC-write VM exits.

The priority of an APIC-access VM exit caused by physical access is not defined relative to other events that the access may cause.

It is recommended that software not set the APIC-access address to any of the addresses used by physical memory accesses (identified above). For example, it should not set the APIC-access address to the physical address of any of the active paging structures if the "enable EPT" VM-execution control is 0.

1. Technically, these accesses do not occur in VMX non-root operation. They are included here for clarity.

## 29.5 VIRTUALIZING MSR-BASED APIC ACCESSES

When the local APIC is in x2APIC mode, software accesses the local APIC's control registers using the MSR interface. Specifically, software uses the RDMSR and WRMSR instructions, setting ECX (identifying the MSR being accessed) to values in the range 800H–8FFH (see Section 10.12, "Extended XAPIC (x2APIC)"). This section describes how these accesses can be virtualized.

A virtual-machine monitor can virtualize these MSR-based APIC accesses by configuring the MSR bitmaps (see Section 24.6.9) to ensure that the accesses cause VM exits (see Section 25.1.3). Alternatively, there are methods for virtualizing some MSR-based APIC accesses without VM exits.

Normally, an execution of RDMSR or WRMSR that does not fault or cause a VM exit accesses the MSR indicated in ECX. However, such an execution treats some values of ECX in the range 800H–8FFH specially if the "virtualize x2APIC mode" VM-execution control is 1. The following items provide details:

- **RDMSR.** The instruction's behavior depends on the setting of the "APIC-register virtualization" VM-execution control.
  - — If the "APIC-register virtualization" VM-execution control is 0, behavior depends upon the value of ECX.
    - If ECX contains 808H (indicating the TPR MSR), the instruction reads the 8 bytes from offset 080H on the virtual-APIC page (VTPR and the 4 bytes above it) into EDX:EAX. This occurs even if the local APIC is not in x2APIC mode (no general-protection fault occurs because the local APIC is not x2APIC mode).
    - If ECX contains any other value in the range 800H–8FFH, the instruction operates normally. If the local APIC is in x2APIC mode and ECX indicates a readable APIC register, EDX and EAX are loaded with the value of that register. If the local APIC is not in x2APIC mode or ECX does not indicate a readable APIC register, a general-protection fault occurs.
  - — If "APIC-register virtualization" is 1 and ECX contains a value in the range 800H–8FFH, the instruction reads the 8 bytes from offset X on the virtual-APIC page into EDX:EAX, where X = (ECX & FFH) « 4. This occurs even if the local APIC is not in x2APIC mode (no general-protection fault occurs because the local APIC is not in x2APIC mode).
- **WRMSR.** The instruction's behavior depends on the value of ECX and the setting of the "virtual-interrupt delivery" VM-execution control.

  Special processing applies in the following cases: (1) ECX contains 808H (indicating the TPR MSR); (2) ECX contains 80BH (indicating the EOI MSR) and the "virtual-interrupt delivery" VM-execution control is 1; and (3) ECX contains 83FH (indicating the self-IPI MSR) and the "virtual-interrupt delivery" VM-execution control is 1.

  If special processing applies, no general-protection exception is produced due to the fact that the local APIC is in xAPIC mode. However, WRMSR does perform the normal reserved-bit checking:

  — If ECX contains 808H or 83FH, a general-protection fault occurs if either EDX or EAX[31:8] is non-zero.

  — If ECX contains 80BH, a general-protection fault occurs if either EDX or EAX is non-zero.

  If there is no fault, WRMSR stores EDX:EAX at offset X on the virtual-APIC page, where X = (ECX & FFH) « 4. Following this, the processor performs an operation depending on the value of ECX:

  — If ECX contains 808H, the processor performs TPR virtualization (see Section 29.1.2).

  — If ECX contains 80BH, the processor performs EOI virtualization (see Section 29.1.4).

  — If ECX contains 83FH, the processor It then checks the value of EAX[7:4] and proceeds as follows:
    - If the value is non-zero, the logical processor performs self-IPI virtualization with the 8-bit vector in EAX[7:0] (see Section 29.1.5).
    - If the value is zero, the logical processor causes an APIC-write VM exit as if there had been a write access to page offset 3F0H on the APIC-access page (see Section 29.4.3.3).

  If special processing does not apply, the instruction operates normally. If the local APIC is in x2APIC mode and ECX indicates a writeable APIC register, the value in EDX:EAX is written to that register. If the local APIC is not in x2APIC mode or ECX does not indicate a writeable APIC register, a general-protection fault occurs.

## 29.6 POSTED-INTERRUPT PROCESSING

Posted-interrupt processing is a feature by which a processor processes the virtual interrupts by recording them as pending on the virtual-APIC page.

Posted-interrupt processing is enabled by setting the "process posted interrupts" VM-execution control. The processing is performed in response to the arrival of an interrupt with the **posted-interrupt notification vector**. In response to such an interrupt, the processor processes virtual interrupts recorded in a data structure called a **posted-interrupt descriptor**. The posted-interrupt notification vector and the address of the posted-interrupt descriptor are fields in the VMCS; see Section 24.6.8.

If the "process posted interrupts" VM-execution control is 1, a logical processor uses a 64-byte posted-interrupt descriptor located at the posted-interrupt descriptor address. The posted-interrupt descriptor has the following format:

**Table 29-1. Format of Posted-Interrupt Descriptor**

| Bit Position(s) | Name | Description |
|---|---|---|
| 255:0 | Posted-interrupt requests | One bit for each interrupt vector. There is a posted-interrupt request for a vector if the corresponding bit is 1 |
| 256 | Outstanding notification | If this bit is set, there is a notification outstanding for one or more posted interrupts in bits 255:0 |
| 511:257 | Reserved for software and other agents | These bits may be used by software and by other agents in the system (e.g., chipset). The processor does not modify these bits. |

The notation **PIR** (posted-interrupt requests) refers to the 256 posted-interrupt bits in the posted-interrupt descriptor.

Use of the posted-interrupt descriptor differs from that of other data structures that are referenced by pointers in a VMCS. There is a general requirement that software ensure that each such data structure is modified only when no logical processor with a current VMCS that references it is in VMX non-root operation. That requirement does not apply to the posted-interrupt descriptor. There is a requirement, however, that such modifications be done using locked read-modify-write instructions.

If the "external-interrupt exiting" VM-execution control is 1, any unmasked external interrupt causes a VM exit (see Section 25.2). If the "process posted interrupts" VM-execution control is also 1, this behavior is changed and the processor handles an external interrupt as follows:[1]

1. The local APIC is acknowledged; this provides the processor core with an interrupt vector, called here the **physical vector**.
2. If the physical vector equals the posted-interrupt notification vector, the logical processor continues to the next step. Otherwise, a VM exit occurs as it would normally due to an external interrupt; the vector is saved in the VM-exit interruption-information field.
3. The processor clears the outstanding-notification bit in the posted-interrupt descriptor. This is done atomically so as to leave the remainder of the descriptor unmodified (e.g., with a locked AND operation).
4. The processor writes zero to the EOI register in the local APIC; this dismisses the interrupt with the posted-interrupt notification vector from the local APIC.
5. The logical processor performs a logical-OR of PIR into VIRR and clears PIR. No other agent can read or write a PIR bit (or group of bits) between the time it is read (to determine what to OR into VIRR) and when it is cleared.
6. The logical processor sets RVI to be the maximum of the old value of RVI and the highest index of all bits that were set in PIR; if no bit was set in PIR, RVI is left unmodified.
7. The logical processor evaluates pending virtual interrupts as described in Section 29.2.1.

The logical processor performs the steps above in an uninterruptible manner. If step #7 leads to recognition of a virtual interrupt, the processor may deliver that interrupt immediately.

1. VM entry ensures that the "process posted interrupts" VM-execution control is 1 only if the "external-interrupt exiting" VM-execution control is also 1. SeeSection 26.2.1.1.

Steps #1 to #7 above occur when the interrupt controller delivers an unmasked external interrupt to the CPU core. This delivery can occur when the logical processor is in the active, HLT, or MWAIT states. If the logical processor had been in the active or MWAIT state before the arrival of the interrupt, it is in the active state following completion of step #7; if it had been in the HLT state, it returns to the HLT state after step #7 (if a pending virtual interrupt was recognized, the logical processor may immediately wake from the HLT state).

# CHAPTER 30
# VMX INSTRUCTION REFERENCE

**NOTE**

This chapter was previously located in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B* as chapter 5.

## 30.1 OVERVIEW

This chapter describes the virtual-machine extensions (VMX) for the Intel 64 and IA-32 architectures. VMX is intended to support virtualization of processor hardware and a system software layer acting as a host to multiple guest software environments. The virtual-machine extensions (VMX) includes five instructions that manage the virtual-machine control structure (VMCS), four instructions that manage VMX operation, two TLB-management instructions, and two instructions for use by guest software. Additional details of VMX are described in Chapter 23 through Chapter 29.

The behavior of the VMCS-maintenance instructions is summarized below:

- **VMPTRLD —** This instruction takes a single 64-bit source operand that is in memory. It makes the referenced VMCS active and current, loading the current-VMCS pointer with this operand and establishes the current VMCS based on the contents of VMCS-data area in the referenced VMCS region. Because this makes the referenced VMCS active, a logical processor may start maintaining on the processor some of the VMCS data for the VMCS.
- **VMPTRST —** This instruction takes a single 64-bit destination operand that is in memory. The current-VMCS pointer is stored into the destination operand.
- **VMCLEAR —** This instruction takes a single 64-bit operand that is in memory. The instruction sets the launch state of the VMCS referenced by the operand to "clear", renders that VMCS inactive, and ensures that data for the VMCS have been written to the VMCS-data area in the referenced VMCS region. If the operand is the same as the current-VMCS pointer, that pointer is made invalid.
- **VMREAD —** This instruction reads a component from a VMCS (the encoding of that field is given in a register operand) and stores it into a destination operand that may be a register or in memory.
- **VMWRITE —** This instruction writes a component to a VMCS (the encoding of that field is given in a register operand) from a source operand that may be a register or in memory.

The behavior of the VMX management instructions is summarized below:

- **VMLAUNCH —** This instruction launches a virtual machine managed by the VMCS. A VM entry occurs, transferring control to the VM.
- **VMRESUME —** This instruction resumes a virtual machine managed by the VMCS. A VM entry occurs, transferring control to the VM.
- **VMXOFF —** This instruction causes the processor to leave VMX operation.
- **VMXON —** This instruction takes a single 64-bit source operand that is in memory. It causes a logical processor to enter VMX root operation and to use the memory referenced by the operand to support VMX operation.

The behavior of the VMX-specific TLB-management instructions is summarized below:

- **INVEPT —** This instruction invalidates entries in the TLBs and paging-structure caches that were derived from extended page tables (EPT).
- **INVVPID —** This instruction invalidates entries in the TLBs and paging-structure caches based on a Virtual-Processor Identifier (VPID).

None of the instructions above can be executed in compatibility mode; they generate invalid-opcode exceptions if executed in compatibility mode.

The behavior of the guest-available instructions is summarized below:

- **VMCALL —** This instruction allows software in VMX non-root operation to call the VMM for service. A VM exit occurs, transferring control to the VMM.

- **VMFUNC —** This instruction allows software in VMX non-root operation to invoke a VM function (processor functionality enabled and configured by software in VMX root operation) without a VM exit.

## 30.2 CONVENTIONS

The operation sections for the VMX instructions in Section 30.3 use the pseudo-function VMexit, which indicates that the logical processor performs a VM exit.

The operation sections also use the pseudo-functions VMsucceed, VMfail, VMfailInvalid, and VMfailValid. These pseudo-functions signal instruction success or failure by setting or clearing bits in RFLAGS and, in some cases, by writing the VM-instruction error field. The following pseudocode fragments detail these functions:

```
VMsucceed:
    CF ← 0;
    PF ← 0;
    AF ← 0;
    ZF ← 0;
    SF ← 0;
    OF ← 0;

VMfail(ErrorNumber):
    IF VMCS pointer is valid
        THEN VMfailValid(ErrorNumber);
        ELSE VMfailInvalid;
    FI;

VMfailInvalid:
    CF ← 1;
    PF ← 0;
    AF ← 0;
    ZF ← 0;
    SF ← 0;
    OF ← 0;

VMfailValid(ErrorNumber):// executed only if there is a current VMCS
    CF ← 0;
    PF ← 0;
    AF ← 0;
    ZF ← 1;
    SF ← 0;
    OF ← 0;
    Set the VM-instruction error field to ErrorNumber;
```

The different VM-instruction error numbers are enumerated in Section 30.4, “VM Instruction Error Numbers”.

## 30.3 VMX INSTRUCTIONS

This section provides detailed descriptions of the VMX instructions.

# INVEPT— Invalidate Translations Derived from EPT

| Opcode | Instruction | Description |
|---|---|---|
| 66 0F 38 80 | INVEPT r64, m128 | Invalidates EPT-derived entries in the TLBs and paging-structure caches (in 64-bit mode) |
| 66 0F 38 80 | INVEPT r32, m128 | Invalidates EPT-derived entries in the TLBs and paging-structure caches (outside 64-bit mode) |

## Description

Invalidates mappings in the translation lookaside buffers (TLBs) and paging-structure caches that were derived from extended page tables (EPT). (See Chapter 28, "VMX Support for Address Translation".) Invalidation is based on the **INVEPT type** specified in the register operand and the **INVEPT descriptor** specified in the memory operand.

Outside IA-32e mode, the register operand is always 32 bits, regardless of the value of CS.D; in 64-bit mode, the register operand has 64 bits (the instruction cannot be executed in compatibility mode).

The INVEPT types supported by a logical processors are reported in the IA32_VMX_EPT_VPID_CAP MSR (see Appendix A, "VMX Capability Reporting Facility"). There are two INVEPT types currently defined:

- Single-context invalidation. If the INVEPT type is 1, the logical processor invalidates all mappings associated with bits 51:12 of the EPT pointer (EPTP) specified in the INVEPT descriptor. It may invalidate other mappings as well.
- Global invalidation: If the INVEPT type is 2, the logical processor invalidates mappings associated with all EPTPs.

If an unsupported INVEPT type is specified, the instruction fails.

INVEPT invalidates all the specified mappings for the indicated EPTP(s) regardless of the VPID and PCID values with which those mappings may be associated.

The INVEPT descriptor comprises 128 bits and contains a 64-bit EPTP value in bits 63:0 (see Figure 30-1).

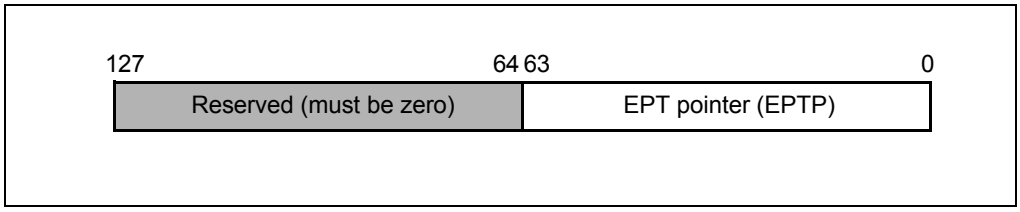

Figure 30-1. INVEPT Descriptor

## Operation

```
IF (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VM exit;
ELSIF CPL > 0
    THEN #GP(0);
    ELSE
        INVEPT_TYPE ← value of register operand;
        IF IA32_VMX_EPT_VPID_CAP MSR indicates that processor does not support INVEPT_TYPE
            THEN VMfail(Invalid operand to INVEPT/INVVPID);
            ELSE      // INVEPT_TYPE must be 1 or 2
                INVEPT_DESC ← value of memory operand;
                EPTP ← INVEPT_DESC[63:0];
```

```
                CASE INVEPT_TYPE OF
                    1:          // single-context invalidation
                        IF VM entry with the "enable EPT" VM execution control set to 1
                        would fail due to the EPTP value
                            THEN VMfail(Invalid operand to INVEPT/INVVPID);
                            ELSE
                                Invalidate mappings associated with EPTP[51:12];
                                VMsucceed;
                        FI;
                        BREAK;
                    2:          // global invalidation
                        Invalidate mappings associated with all EPTPs;
                        VMsucceed;
                        BREAK;
                ESAC;
        FI;
FI;
```

## Flags Affected

See the operation section and Section 30.2.

## Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit. |
| | If the DS, ES, FS, or GS register contains an unusable segment. |
| | If the source operand is located in an execute-only code segment. |
| #PF(fault-code) | If a page fault occurs in accessing the memory operand. |
| #SS(0) | If the memory operand effective address is outside the SS segment limit. |
| | If the SS register contains an unusable segment. |
| #UD | If not in VMX operation. |
| | If the logical processor does not support EPT (IA32_VMX_PROCBASED_CTLS2[33]=0). |
| | If the logical processor supports EPT (IA32_VMX_PROCBASED_CTLS2[33]=1) but does not support the INVEPT instruction (IA32_VMX_EPT_VPID_CAP[20]=0). |

## Real-Address Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX root operation. |

## Virtual-8086 Mode Exceptions

| | |
|---|---|
| #UD | The INVEPT instruction is not recognized in virtual-8086 mode. |

## Compatibility Mode Exceptions

| | |
|---|---|
| #UD | The INVEPT instruction is not recognized in compatibility mode. |

## 64-Bit Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the memory operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form. |
| #PF(fault-code) | If a page fault occurs in accessing the memory operand. |
| #SS(0) | If the memory operand is in the SS segment and the memory address is in a non-canonical form. |

| | |
|---|---|
| #UD | If not in VMX operation.<br>If the logical processor does not support EPT (IA32_VMX_PROCBASED_CTLS2[33]=0).<br>If the logical processor supports EPT (IA32_VMX_PROCBASED_CTLS2[33]=1) but does not support the INVEPT instruction (IA32_VMX_EPT_VPID_CAP[20]=0). |

## INVVPID— Invalidate Translations Based on VPID

| Opcode | Instruction | Description |
|---|---|---|
| 66 0F 38 81 | INVVPID r64, m128 | Invalidates entries in the TLBs and paging-structure caches based on VPID (in 64-bit mode) |
| 66 0F 38 81 | INVVPID r32, m128 | Invalidates entries in the TLBs and paging-structure caches based on VPID (outside 64-bit mode) |

### Description

Invalidates mappings in the translation lookaside buffers (TLBs) and paging-structure caches based on **virtual-processor identifier** (VPID). (See Chapter 28, "VMX Support for Address Translation".) Invalidation is based on the **INVVPID type** specified in the register operand and the **INVVPID descriptor** specified in the memory operand.

Outside IA-32e mode, the register operand is always 32 bits, regardless of the value of CS.D; in 64-bit mode, the register operand has 64 bits (the instruction cannot be executed in compatibility mode).

The INVVPID types supported by a logical processors are reported in the IA32_VMX_EPT_VPID_CAP MSR (see Appendix A, "VMX Capability Reporting Facility"). There are four INVVPID types currently defined:

- Individual-address invalidation: If the INVVPID type is 0, the logical processor invalidates mappings for the linear address and VPID specified in the INVVPID descriptor. In some cases, it may invalidate mappings for other linear addresses (or other VPIDs) as well.
- Single-context invalidation: If the INVVPID type is 1, the logical processor invalidates all mappings tagged with the VPID specified in the INVVPID descriptor. In some cases, it may invalidate mappings for other VPIDs as well.
- All-contexts invalidation: If the INVVPID type is 2, the logical processor invalidates all mappings tagged with all VPIDs except VPID 0000H. In some cases, it may invalidate translations with VPID 0000H as well.
- Single-context invalidation, retaining global translations: If the INVVPID type is 3, the logical processor invalidates all mappings tagged with the VPID specified in the INVVPID descriptor except global translations. In some cases, it may invalidate global translations (and mappings with other VPIDs) as well. See the "Caching Translation Information" section in Chapter 4 of the *IA-32 Intel Architecture Software Developer's Manual, Volumes 3A* for information about global translations.

If an unsupported INVVPID type is specified, the instruction fails.

INVVPID invalidates all the specified mappings for the indicated VPID(s) regardless of the EPTP and PCID values with which those mappings may be associated.

The INVVPID descriptor comprises 128 bits and consists of a VPID and a linear address as shown in Figure 30-2.

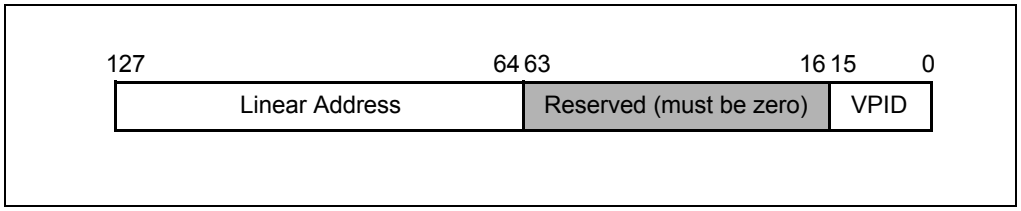

Figure 30-2. INVVPID Descriptor

## Operation

```
IF (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VM exit;
ELSIF CPL > 0
    THEN #GP(0);
    ELSE
        INVVPID_TYPE ← value of register operand;
        IF IA32_VMX_EPT_VPID_CAP MSR indicates that processor does not support
        INVVPID_TYPE
            THEN VMfail(Invalid operand to INVEPT/INVVPID);
            ELSE            // INVVPID_TYPE must be in the range 0–3
                INVVPID_DESC ← value of memory operand;
                IF INVVPID_DESC[63:16] ≠ 0
                    THEN VMfail(Invalid operand to INVEPT/INVVPID);
                    ELSE
                        CASE INVVPID_TYPE OF
                            0:                  // individual-address invalidation
                                VPID ← INVVPID_DESC[15:0];
                                IF VPID = 0
                                    THEN VMfail(Invalid operand to INVEPT/INVVPID);
                                    ELSE
                                        GL_ADDR ← INVVPID_DESC[127:64];
                                        IF (GL_ADDR is not in a canonical form)
                                            THEN
                                                VMfail(Invalid operand to INVEPT/INVVPID);
                                            ELSE
                                                Invalidate mappings for GL_ADDR tagged with VPID;
                                                VMsucceed;
                                        FI;
                                FI;
                                BREAK;
                            1:                  // single-context invalidation
                                VPID ← INVVPID_DESC[15:0];
                                IF VPID = 0
                                    THEN VMfail(Invalid operand to INVEPT/INVVPID);
                                    ELSE
                                        Invalidate all mappings tagged with VPID;
                                        VMsucceed;
                                FI;
                                BREAK;
                            2:                  // all-context invalidation
                                Invalidate all mappings tagged with all non-zero VPIDs;
                                VMsucceed;
                                BREAK;
                            3:                  // single-context invalidation retaining globals
                                VPID ← INVVPID_DESC[15:0];
                                IF VPID = 0
                                    THEN VMfail(Invalid operand to INVEPT/INVVPID);
                                    ELSE
                                        Invalidate all mappings tagged with VPID except global translations;
                                        VMsucceed;
```

```
                        FI;
                        BREAK;
                ESAC;
        FI;
    FI;
FI;
```

## Flags Affected

See the operation section and Section 30.2.

## Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit. |
| | If the DS, ES, FS, or GS register contains an unusable segment. |
| | If the source operand is located in an execute-only code segment. |
| #PF(fault-code) | If a page fault occurs in accessing the memory operand. |
| #SS(0) | If the memory operand effective address is outside the SS segment limit. |
| | If the SS register contains an unusable segment. |
| #UD | If not in VMX operation. |
| | If the logical processor does not support VPIDs (IA32_VMX_PROCBASED_CTLS2[37]=0). |
| | If the logical processor supports VPIDs (IA32_VMX_PROCBASED_CTLS2[37]=1) but does not support the INVVPID instruction (IA32_VMX_EPT_VPID_CAP[32]=0). |

## Real-Address Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX root operation. |

## Virtual-8086 Mode Exceptions

| | |
|---|---|
| #UD | The INVVPID instruction is not recognized in virtual-8086 mode. |

## Compatibility Mode Exceptions

| | |
|---|---|
| #UD | The INVVPID instruction is not recognized in compatibility mode. |

## 64-Bit Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the memory operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form. |
| #PF(fault-code) | If a page fault occurs in accessing the memory operand. |
| #SS(0) | If the memory destination operand is in the SS segment and the memory address is in a non-canonical form. |
| #UD | If not in VMX operation. |
| | If the logical processor does not support VPIDs (IA32_VMX_PROCBASED_CTLS2[37]=0). |
| | If the logical processor supports VPIDs (IA32_VMX_PROCBASED_CTLS2[37]=1) but does not support the INVVPID instruction (IA32_VMX_EPT_VPID_CAP[32]=0). |

# VMCALL—Call to VM Monitor

| Opcode | Instruction | Description |
|---|---|---|
| 0F 01 C1 | VMCALL | Call to VM monitor by causing VM exit. |

## Description

This instruction allows guest software can make a call for service into an underlying VM monitor. The details of the programming interface for such calls are VMM-specific; this instruction does nothing more than cause a VM exit, registering the appropriate exit reason.

Use of this instruction in VMX root operation invokes an SMM monitor (see Section 34.15.2). This invocation will activate the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM) if it is not already active (see Section 34.15.6).

## Operation

```
IF not in VMX operation
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VM exit;
ELSIF (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF CPL > 0
    THEN #GP(0);
ELSIF in SMM or the logical processor does not support the dual-monitor treatment of SMIs and SMM or the valid bit in the
IA32_SMM_MONITOR_CTL MSR is clear
    THEN VMfail (VMCALL executed in VMX root operation);
ELSIF dual-monitor treatment of SMIs and SMM is active
    THEN perform an SMM VM exit (see Section 34.15.2);
ELSIF current-VMCS pointer is not valid
    THEN VMfailInvalid;
ELSIF launch state of current VMCS is not clear
    THEN VMfailValid(VMCALL with non-clear VMCS);
ELSIF VM-exit control fields are not valid (see Section 34.15.6.1)
    THEN VMfailValid (VMCALL with invalid VM-exit control fields);
ELSE
    enter SMM;
    read revision identifier in MSEG;
    IF revision identifier does not match that supported by processor
        THEN
            leave SMM;
            VMfailValid(VMCALL with incorrect MSEG revision identifier);
        ELSE
            read SMM-monitor features field in MSEG (see Section 34.15.6.2);
            IF features field is invalid
                THEN
                    leave SMM;
                    VMfailValid(VMCALL with invalid SMM-monitor features);
                ELSE activate dual-monitor treatment of SMIs and SMM (see Section 34.15.6);
            FI;
        FI;
FI;
```

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0 and the logical processor is in VMX root operation. |
| #UD | If executed outside VMX operation. |

| #UD | If executed outside VMX non-root operation. |

### 64-Bit Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX operation. |

# VMCLEAR—Clear Virtual-Machine Control Structure

| Opcode | Instruction | Description |
|---|---|---|
| 66 0F C7 /6 | VMCLEAR m64 | Copy VMCS data to VMCS region in memory. |

## Description

This instruction applies to the VMCS whose VMCS region resides at the physical address contained in the instruction operand. The instruction ensures that VMCS data for that VMCS (some of these data may be currently maintained on the processor) are copied to the VMCS region in memory. It also initializes parts of the VMCS region (for example, it sets the launch state of that VMCS to clear). See Chapter 24, "Virtual-Machine Control Structures".

The operand of this instruction is always 64 bits and is always in memory. If the operand is the current-VMCS pointer, then that pointer is made invalid (set to FFFFFFFF_FFFFFFFFH).

Note that the VMCLEAR instruction might not explicitly write any VMCS data to memory; the data may be already resident in memory before the VMCLEAR is executed.

## Operation

```
IF (register operand) or (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VM exit;
ELSIF CPL > 0
    THEN #GP(0);
    ELSE
        addr ← contents of 64-bit in-memory operand;
        IF addr is not 4KB-aligned OR
        addr sets any bits beyond the physical-address width[1]
            THEN VMfail(VMCLEAR with invalid physical address);
        ELSIF addr = VMXON pointer
            THEN VMfail(VMCLEAR with VMXON pointer);
            ELSE
                ensure that data for VMCS referenced by the operand is in memory;
                initialize implementation-specific data in VMCS region;
                launch state of VMCS referenced by the operand ← "clear"
                IF operand addr = current-VMCS pointer
                    THEN current-VMCS pointer ← FFFFFFFF_FFFFFFFFH;
                FI;
                VMsucceed;
        FI;
FI;
```

## Flags Affected

See the operation section and Section 30.2.

## Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit. |
| | If the DS, ES, FS, or GS register contains an unusable segment. |
| | If the operand is located in an execute-only code segment. |

1. If IA32_VMX_BASIC[48] is read as 1, VMfail occurs if addr sets any bits in the range 63:32; see Appendix A.1.

| | |
|---|---|
| #PF(fault-code) | If a page fault occurs in accessing the memory operand. |
| #SS(0) | If the memory operand effective address is outside the SS segment limit. |
| | If the SS register contains an unusable segment. |
| #UD | If operand is a register. |
| | If not in VMX operation. |

### Real-Address Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX root operation. |

### Virtual-8086 Mode Exceptions

| | |
|---|---|
| #UD | The VMCLEAR instruction is not recognized in virtual-8086 mode. |

### Compatibility Mode Exceptions

| | |
|---|---|
| #UD | The VMCLEAR instruction is not recognized in compatibility mode. |

### 64-Bit Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the source operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form. |
| #PF(fault-code) | If a page fault occurs in accessing the memory operand. |
| #SS(0) | If the source operand is in the SS segment and the memory address is in a non-canonical form. |
| #UD | If operand is a register. |
| | If not in VMX operation. |

# VMFUNC—Invoke VM function

| Opcode | Instruction | Description |
|---|---|---|
| 0F 01 D4 | VMFUNC | Invoke VM function specified in EAX. |

## Description

This instruction allows software in VMX non-root operation to invoke a VM function, which is processor functionality enabled and configured by software in VMX root operation. The value of EAX selects the specific VM function being invoked.

The behavior of each VM function (including any additional fault checking) is specified in Section 25.5.5, "VM Functions".

## Operation

Perform functionality of the VM function specified in EAX;

## Flags Affected

Depends on the VM function specified in EAX. See Section 25.5.5, "VM Functions".

## Protected Mode Exceptions (not including those defined by specific VM functions)

| | |
|---|---|
| #UD | If executed outside VMX non-root operation. |
| | If "enable VM functions" VM-execution control is 0. |
| | If EAX ≥ 64. |

## Real-Address Mode Exceptions

Same exceptions as in protected mode.

## Virtual-8086 Exceptions

Same exceptions as in protected mode.

## Compatibility Mode Exceptions

Same exceptions as in protected mode.

## 64-Bit Mode Exceptions

Same exceptions as in protected mode.

# VMLAUNCH/VMRESUME—Launch/Resume Virtual Machine

| Opcode | Instruction | Description |
|---|---|---|
| 0F 01 C2 | VMLAUNCH | Launch virtual machine managed by current VMCS. |
| 0F 01 C3 | VMRESUME | Resume virtual machine managed by current VMCS. |

## Description

Effects a VM entry managed by the current VMCS.

- VMLAUNCH fails if the launch state of current VMCS is not "clear". If the instruction is successful, it sets the launch state to "launched."
- VMRESUME fails if the launch state of the current VMCS is not "launched."

If VM entry is attempted, the logical processor performs a series of consistency checks as detailed in Chapter 26, "VM Entries". Failure to pass checks on the VMX controls or on the host-state area passes control to the instruction following the VMLAUNCH or VMRESUME instruction. If these pass but checks on the guest-state area fail, the logical processor loads state from the host-state area of the VMCS, passing control to the instruction referenced by the RIP field in the host-state area.

VM entry is not allowed when events are blocked by MOV SS or POP SS. Neither VMLAUNCH nor VMRESUME should be used immediately after either MOV to SS or POP to SS.

## Operation

```
IF (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VMexit;
ELSIF CPL > 0
    THEN #GP(0);
ELSIF current-VMCS pointer is not valid
    THEN VMfailInvalid;
ELSIF events are being blocked by MOV SS
    THEN VMfailValid(VM entry with events blocked by MOV SS);
ELSIF (VMLAUNCH and launch state of current VMCS is not "clear")
    THEN VMfailValid(VMLAUNCH with non-clear VMCS);
ELSIF (VMRESUME and launch state of current VMCS is not "launched")
    THEN VMfailValid(VMRESUME with non-launched VMCS);
    ELSE
        Check settings of VMX controls and host-state area;
        IF invalid settings
            THEN VMfailValid(VM entry with invalid VMX-control field(s)) or
                    VMfailValid(VM entry with invalid host-state field(s)) or
                    VMfailValid(VM entry with invalid executive-VMCS pointer)) or
                    VMfailValid(VM entry with non-launched executive VMCS) or
                    VMfailValid(VM entry with executive-VMCS pointer not VMXON pointer) or
                    VMfailValid(VM entry with invalid VM-execution control fields in executive
                    VMCS)
                    as appropriate;
            ELSE
                Attempt to load guest state and PDPTRs as appropriate;
                clear address-range monitoring;
                IF failure in checking guest state or PDPTRs
                    THEN VM entry fails (see Section 26.7);
```

```
                    ELSE
                        Attempt to load MSRs from VM-entry MSR-load area;
                        IF failure
                            THEN VM entry fails
                            (see Section 26.7);
                            ELSE
                                IF VMLAUNCH
                                    THEN launch state of VMCS ← "launched";
                                FI;
                                IF in SMM and "entry to SMM" VM-entry control is 0
                                    THEN
                                        IF "deactivate dual-monitor treatment" VM-entry
                                        control is 0
                                            THEN SMM-transfer VMCS pointer ←
                                            current-VMCS pointer;
                                        FI;
                                        IF executive-VMCS pointer is VMXON pointer
                                            THEN current-VMCS pointer ←
                                            VMCS-link pointer;
                                            ELSE current-VMCS pointer ←
                                            executive-VMCS pointer;
                                        FI;
                                        leave SMM;
                                FI;
                                VM entry succeeds;
                        FI;
                FI;
        FI;
FI;
```

Further details of the operation of the VM-entry appear in Chapter 26.

## Flags Affected

See the operation section and Section 30.2.

## Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |

## VMPTRLD—Load Pointer to Virtual-Machine Control Structure

| Opcode | Instruction | Description |
|---|---|---|
| 0F C7 /6 | VMPTRLD m64 | Loads the current VMCS pointer from memory. |

### Description

Marks the current-VMCS pointer valid and loads it with the physical address in the instruction operand. The instruction fails if its operand is not properly aligned, sets unsupported physical-address bits, or is equal to the VMXON pointer. In addition, the instruction fails if the 32 bits in memory referenced by the operand do not match the VMCS revision identifier supported by this processor.[2]

The operand of this instruction is always 64 bits and is always in memory.

### Operation

```
IF (register operand) or (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VMexit;
ELSIF CPL > 0
    THEN #GP(0);
    ELSE
        addr ← contents of 64-bit in-memory source operand;
        IF addr is not 4KB-aligned OR
        addr sets any bits beyond the physical-address width[3]
            THEN VMfail(VMPTRLD with invalid physical address);
        ELSIF addr = VMXON pointer
            THEN VMfail(VMPTRLD with VMXON pointer);
            ELSE
                rev ← 32 bits located at physical address addr;
                IF rev[30:0] ≠ VMCS revision identifier supported by processor OR
                rev[31] = 1 AND processor does not support 1-setting of "VMCS shadowing"
                    THEN VMfail(VMPTRLD with incorrect VMCS revision identifier);
                    ELSE
                        current-VMCS pointer ← addr;
                        VMsucceed;
                FI;
        FI;
FI;
```

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the memory source operand effective address is outside the CS, DS, ES, FS, or GS segment limit. |
| | If the DS, ES, FS, or GS register contains an unusable segment. |

2. Software should consult the VMX capability MSR VMX_BASIC to discover the VMCS revision identifier supported by this processor (see Appendix A, "VMX Capability Reporting Facility").
3. If IA32_VMX_BASIC[48] is read as 1, VMfail occurs if addr sets any bits in the range 63:32; see Appendix A.1.

| | |
|---|---|
| | If the source operand is located in an execute-only code segment. |
| #PF(fault-code) | If a page fault occurs in accessing the memory source operand. |
| #SS(0) | If the memory source operand effective address is outside the SS segment limit. |
| | If the SS register contains an unusable segment. |
| #UD | If operand is a register. |
| | If not in VMX operation. |

### Real-Address Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX root operation. |

### Virtual-8086 Mode Exceptions

| | |
|---|---|
| #UD | The VMPTRLD instruction is not recognized in virtual-8086 mode. |

### Compatibility Mode Exceptions

| | |
|---|---|
| #UD | The VMPTRLD instruction is not recognized in compatibility mode. |

### 64-Bit Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the source operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form. |
| #PF(fault-code) | If a page fault occurs in accessing the memory source operand. |
| #SS(0) | If the source operand is in the SS segment and the memory address is in a non-canonical form. |
| #UD | If operand is a register. |
| | If not in VMX operation. |

# VMPTRST—Store Pointer to Virtual-Machine Control Structure

| Opcode | Instruction | Description |
|---|---|---|
| 0F C7 /7 | VMPTRST m64 | Stores the current VMCS pointer into memory. |

## Description

Stores the current-VMCS pointer into a specified memory address. The operand of this instruction is always 64 bits and is always in memory.

## Operation

```
IF (register operand) or (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VMexit;
ELSIF CPL > 0
    THEN #GP(0);
    ELSE
        64-bit in-memory destination operand ← current-VMCS pointer;
        VMsucceed;
FI;
```

## Flags Affected

See the operation section and Section 30.2.

## Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the memory destination operand effective address is outside the CS, DS, ES, FS, or GS segment limit. |
| | If the DS, ES, FS, or GS register contains an unusable segment. |
| | If the destination operand is located in a read-only data segment or any code segment. |
| #PF(fault-code) | If a page fault occurs in accessing the memory destination operand. |
| #SS(0) | If the memory destination operand effective address is outside the SS segment limit. |
| | If the SS register contains an unusable segment. |
| #UD | If operand is a register. |
| | If not in VMX operation. |

## Real-Address Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX root operation. |

## Virtual-8086 Mode Exceptions

| | |
|---|---|
| #UD | The VMPTRST instruction is not recognized in virtual-8086 mode. |

## Compatibility Mode Exceptions

| | |
|---|---|
| #UD | The VMPTRST instruction is not recognized in compatibility mode. |

### 64-Bit Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the destination operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form. |
| #PF(fault-code) | If a page fault occurs in accessing the memory destination operand. |
| #SS(0) | If the destination operand is in the SS segment and the memory address is in a non-canonical form. |
| #UD | If operand is a register. |
| | If not in VMX operation. |

## VMREAD—Read Field from Virtual-Machine Control Structure

| Opcode | Instruction | Description |
|---|---|---|
| 0F 78 | VMREAD r/m64, r64 | Reads a specified VMCS field (in 64-bit mode). |
| 0F 78 | VMREAD r/m32, r32 | Reads a specified VMCS field (outside 64-bit mode). |

### Description

Reads a specified field from a VMCS and stores it into a specified destination operand (register or memory). In VMX root operation, the instruction reads from the current VMCS. If executed in VMX non-root operation, the instruction reads from the VMCS referenced by the VMCS link pointer field in the current VMCS.

The VMCS field is specified by the VMCS-field encoding contained in the register source operand. Outside IA-32e mode, the source operand has 32 bits, regardless of the value of CS.D. In 64-bit mode, the source operand has 64 bits.

The effective size of the destination operand, which may be a register or in memory, is always 32 bits outside IA-32e mode (the setting of CS.D is ignored with respect to operand size) and 64 bits in 64-bit mode. If the VMCS field specified by the source operand is shorter than this effective operand size, the high bits of the destination operand are cleared to 0. If the VMCS field is longer, then the high bits of the field are not read.

Note that any faults resulting from accessing a memory destination operand can occur only after determining, in the operation section below, that the relevant VMCS pointer is valid and that the specified VMCS field is supported.

### Operation

```
IF (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation AND ("VMCS shadowing" is 0 OR source operand sets bits in range 63:15 OR
VMREAD bit corresponding to bits 14:0 of source operand is 1)[4]
    THEN VMexit;
ELSIF CPL > 0
    THEN #GP(0);
ELSIF (in VMX root operation AND current-VMCS pointer is not valid) OR
(in VMX non-root operation AND VMCS link pointer is not valid)
    THEN VMfailInvalid;
ELSIF source operand does not correspond to any VMCS field
    THEN VMfailValid(VMREAD/VMWRITE from/to unsupported VMCS component);
    ELSE
        IF in VMX root operation
            THEN destination operand ← contents of field indexed by source operand in current VMCS;
            ELSE destination operand ← contents of field indexed by source operand in VMCS referenced by VMCS link pointer;
        FI;
        VMsucceed;
FI;
```

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |

4. The VMREAD bit for a source operand is defined as follows. Let *x* be the value of bits 14:0 of the source operand and let *addr* be the VMREAD-bitmap address. The corresponding VMREAD bit is in bit position *x* & 7 of the byte at physical address *addr* | (x » 3).

| | |
|---|---|
| | If a memory destination operand effective address is outside the CS, DS, ES, FS, or GS segment limit. |
| | If the DS, ES, FS, or GS register contains an unusable segment. |
| | If the destination operand is located in a read-only data segment or any code segment. |
| #PF(fault-code) | If a page fault occurs in accessing a memory destination operand. |
| #SS(0) | If a memory destination operand effective address is outside the SS segment limit. |
| | If the SS register contains an unusable segment. |
| #UD | If not in VMX operation. |

### Real-Address Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX root operation. |

### Virtual-8086 Mode Exceptions

| | |
|---|---|
| #UD | The VMREAD instruction is not recognized in virtual-8086 mode. |

### Compatibility Mode Exceptions

| | |
|---|---|
| #UD | The VMREAD instruction is not recognized in compatibility mode. |

### 64-Bit Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the memory destination operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form. |
| #PF(fault-code) | If a page fault occurs in accessing a memory destination operand. |
| #SS(0) | If the memory destination operand is in the SS segment and the memory address is in a non-canonical form. |
| #UD | If not in VMX operation. |

## VMRESUME—Resume Virtual Machine

See VMLAUNCH/VMRESUME—Launch/Resume Virtual Machine.

# VMWRITE—Write Field to Virtual-Machine Control Structure

| Opcode | Instruction | Description |
|---|---|---|
| 0F 79 | VMWRITE r64, r/m64 | Writes a specified VMCS field (in 64-bit mode) |
| 0F 79 | VMWRITE r32, r/m32 | Writes a specified VMCS field (outside 64-bit mode) |

## Description

Writes the contents of a primary source operand (register or memory) to a specified field in a VMCS. In VMX root operation, the instruction writes to the current VMCS. If executed in VMX non-root operation, the instruction writes to the VMCS referenced by the VMCS link pointer field in the current VMCS.

The VMCS field is specified by the VMCS-field encoding contained in the register secondary source operand. Outside IA-32e mode, the secondary source operand is always 32 bits, regardless of the value of CS.D. In 64-bit mode, the secondary source operand has 64 bits.

The effective size of the primary source operand, which may be a register or in memory, is always 32 bits outside IA-32e mode (the setting of CS.D is ignored with respect to operand size) and 64 bits in 64-bit mode. If the VMCS field specified by the secondary source operand is shorter than this effective operand size, the high bits of the primary source operand are ignored. If the VMCS field is longer, then the high bits of the field are cleared to 0.

Note that any faults resulting from accessing a memory source operand occur after determining, in the operation section below, that the relevant VMCS pointer is valid but before determining if the destination VMCS field is supported.

## Operation

```
IF (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation AND ("VMCS shadowing" is 0 OR secondary source operand sets bits in range 63:15 OR
VMWRITE bit corresponding to bits 14:0 of secondary source operand is 1)[5]
    THEN VMexit;
ELSIF CPL > 0
    THEN #GP(0);
ELSIF (in VMX root operation AND current-VMCS pointer is not valid) OR
(in VMX non-root operation AND VMCS-link pointer is not valid)
    THEN VMfailInvalid;
ELSIF secondary source operand does not correspond to any VMCS field
    THEN VMfailValid(VMREAD/VMWRITE from/to unsupported VMCS component);
ELSIF VMCS field indexed by secondary source operand is a VM-exit information field AND
processor does not support writing to such fields[6]
    THEN VMfailValid(VMWRITE to read-only VMCS component);
    ELSE
        IF in VMX root operation
            THEN field indexed by secondary source operand in current VMCS ← primary source operand;
            ELSE field indexed by secondary source operand in VMCS referenced by VMCS link pointer ← primary source operand;
        FI;
        VMsucceed;
FI;
```

5. The VMWRITE bit for a secondary source operand is defined as follows. Let *x* be the value of bits 14:0 of the secondary source operand and let *addr* be the VMWRITE-bitmap address. The corresponding VMWRITE bit is in bit position *x* & 7 of the byte at physical address *addr* | (x » 3).
6. Software can discover whether these fields can be written by reading the VMX capability MSR IA32_VMX_MISC (see Appendix A.6).

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If a memory source operand effective address is outside the CS, DS, ES, FS, or GS segment limit. |
| | If the DS, ES, FS, or GS register contains an unusable segment. |
| | If the source operand is located in an execute-only code segment. |
| #PF(fault-code) | If a page fault occurs in accessing a memory source operand. |
| #SS(0) | If a memory source operand effective address is outside the SS segment limit. |
| | If the SS register contains an unusable segment. |
| #UD | If not in VMX operation. |

### Real-Address Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX root operation. |

### Virtual-8086 Mode Exceptions

| | |
|---|---|
| #UD | The VMWRITE instruction is not recognized in virtual-8086 mode. |

### Compatibility Mode Exceptions

| | |
|---|---|
| #UD | The VMWRITE instruction is not recognized in compatibility mode. |

### 64-Bit Mode Exceptions

| | |
|---|---|
| #GP(0) | If the current privilege level is not 0. |
| | If the memory source operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form. |
| #PF(fault-code) | If a page fault occurs in accessing a memory source operand. |
| #SS(0) | If the memory source operand is in the SS segment and the memory address is in a non-canonical form. |
| #UD | If not in VMX operation. |

# VMXOFF—Leave VMX Operation

| Opcode | Instruction | Description |
|---|---|---|
| 0F 01 C4 | VMXOFF | Leaves VMX operation. |

## Description

Takes the logical processor out of VMX operation, unblocks INIT signals, conditionally re-enables A20M, and clears any address-range monitoring.[7]

## Operation

```
IF (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VMexit;
ELSIF CPL > 0
    THEN #GP(0);
ELSIF dual-monitor treatment of SMIs and SMM is active
    THEN VMfail(VMXOFF under dual-monitor treatment of SMIs and SMM);
    ELSE
        leave VMX operation;
        unblock INIT;
        IF IA32_SMM_MONITOR_CTL[2] = 0[8]
            THEN unblock SMIs;
        IF outside SMX operation[9]
            THEN unblock and enable A20M;
        FI;
        clear address-range monitoring;
        VMsucceed;
FI;
```

## Flags Affected

See the operation section and Section 30.2.

## Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If executed in VMX root operation with CPL > 0. |
| #UD | If executed outside VMX operation. |

## Real-Address Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX root operation. |

## Virtual-8086 Mode Exceptions

| | |
|---|---|
| #UD | The VMXOFF instruction is not recognized in virtual-8086 mode. |

7. See the information on MONITOR/MWAIT in Chapter 8, "Multiple-Processor Management," of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.
8. Setting IA32_SMM_MONITOR_CTL[bit 2] to 1 prevents VMXOFF from unblocking SMIs regardless of the value of the register's value bit (bit 0). Not all processors allow this bit to be set to 1. Software should consult the VMX capability MSR IA32_VMX_MISC (see Appendix A.6) to determine whether this is allowed.
9. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference."

### Compatibility Mode Exceptions

| | |
|---|---|
| #UD | The VMXOFF instruction is not recognized in compatibility mode. |

### 64-Bit Mode Exceptions

| | |
|---|---|
| #GP(0) | If executed in VMX root operation with CPL > 0. |
| #UD | If executed outside VMX operation. |

# VMXON—Enter VMX Operation

| Opcode | Instruction | Description |
|---|---|---|
| F3 0F C7 /6 | VMXON m64 | Enter VMX root operation. |

## Description

Puts the logical processor in VMX operation with no current VMCS, blocks INIT signals, disables A20M, and clears any address-range monitoring established by the MONITOR instruction.[10]

The operand of this instruction is a 4KB-aligned physical address (the VMXON pointer) that references the VMXON region, which the logical processor may use to support VMX operation. This operand is always 64 bits and is always in memory.

## Operation

```
IF (register operand) or (CR0.PE = 0) or (CR4.VMXE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF not in VMX operation
    THEN
        IF (CPL > 0) or (in A20M mode) or
        (the values of CR0 and CR4 are not supported in VMX operation; see Section 23.8) or
        (bit 0 (lock bit) of IA32_FEATURE_CONTROL MSR is clear) or
        (in SMX operation[11] and bit 1 of IA32_FEATURE_CONTROL MSR is clear) or
        (outside SMX operation and bit 2 of IA32_FEATURE_CONTROL MSR is clear)
            THEN #GP(0);
            ELSE
                addr ← contents of 64-bit in-memory source operand;
                IF addr is not 4KB-aligned or
                addr sets any bits beyond the physical-address width[12]
                    THEN VMfailInvalid;
                    ELSE
                        rev ← 32 bits located at physical address addr;
                        IF rev[30:0] ≠ VMCS revision identifier supported by processor OR rev[31] = 1
                            THEN VMfailInvalid;
                            ELSE
                                current-VMCS pointer ← FFFFFFFF_FFFFFFFFH;
                                enter VMX operation;
                                block INIT signals;
                                block and disable A20M;
                                clear address-range monitoring;
                                VMsucceed;
                        FI;
                FI;
        FI;
ELSIF in VMX non-root operation
    THEN VMexit;
```

10. See the information on MONITOR/MWAIT in Chapter 8, "Multiple-Processor Management," of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.

11. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference."

12. If IA32_VMX_BASIC[48] is read as 1, VMfailInvalid occurs if addr sets any bits in the range 63:32; see Appendix A.1.

```
ELSIF CPL > 0
    THEN #GP(0);
    ELSE VMfail("VMXON executed in VMX root operation");
FI;
```

## Flags Affected

See the operation section and Section 30.2.

## Protected Mode Exceptions

| | |
|---|---|
| #GP(0) | If executed outside VMX operation with CPL>0 or with invalid CR0 or CR4 fixed bits. |
| | If executed in A20M mode. |
| | If the memory source operand effective address is outside the CS, DS, ES, FS, or GS segment limit. |
| | If the DS, ES, FS, or GS register contains an unusable segment. |
| | If the source operand is located in an execute-only code segment. |
| #PF(fault-code) | If a page fault occurs in accessing the memory source operand. |
| #SS(0) | If the memory source operand effective address is outside the SS segment limit. |
| | If the SS register contains an unusable segment. |
| #UD | If operand is a register. |
| | If executed with CR4.VMXE = 0. |

## Real-Address Mode Exceptions

| | |
|---|---|
| #UD | If executed outside VMX root operation. |

## Virtual-8086 Mode Exceptions

| | |
|---|---|
| #UD | The VMXON instruction is not recognized in virtual-8086 mode. |

## Compatibility Mode Exceptions

| | |
|---|---|
| #UD | The VMXON instruction is not recognized in compatibility mode. |

## 64-Bit Mode Exceptions

| | |
|---|---|
| #GP(0) | If executed outside VMX operation with CPL > 0 or with invalid CR0 or CR4 fixed bits. |
| | If executed in A20M mode. |
| | If the source operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form. |
| #PF(fault-code) | If a page fault occurs in accessing the memory source operand. |
| #SS(0) | If the source operand is in the SS segment and the memory address is in a non-canonical form. |
| #UD | If operand is a register. |
| | If executed with CR4.VMXE = 0. |

## 30.4 VM INSTRUCTION ERROR NUMBERS

For certain error conditions, the VM-instruction error field is loaded with an error number to indicate the source of the error. Table 30-1 lists VM-instruction error numbers.

**Table 30-1. VM-Instruction Error Numbers**

| Error Number | Description |
|---|---|
| 1 | VMCALL executed in VMX root operation |
| 2 | VMCLEAR with invalid physical address |
| 3 | VMCLEAR with VMXON pointer |
| 4 | VMLAUNCH with non-clear VMCS |
| 5 | VMRESUME with non-launched VMCS |
| 6 | VMRESUME after VMXOFF (VMXOFF and VMXON between VMLAUNCH and VMRESUME)[1] |
| 7 | VM entry with invalid control field(s)[2,3] |
| 8 | VM entry with invalid host-state field(s)[2] |
| 9 | VMPTRLD with invalid physical address |
| 10 | VMPTRLD with VMXON pointer |
| 11 | VMPTRLD with incorrect VMCS revision identifier |
| 12 | VMREAD/VMWRITE from/to unsupported VMCS component |
| 13 | VMWRITE to read-only VMCS component |
| 15 | VMXON executed in VMX root operation |
| 16 | VM entry with invalid executive-VMCS pointer[2] |
| 17 | VM entry with non-launched executive VMCS[2] |
| 18 | VM entry with executive-VMCS pointer not VMXON pointer (when attempting to deactivate the dual-monitor treatment of SMIs and SMM)[2] |
| 19 | VMCALL with non-clear VMCS (when attempting to activate the dual-monitor treatment of SMIs and SMM) |
| 20 | VMCALL with invalid VM-exit control fields |
| 22 | VMCALL with incorrect MSEG revision identifier (when attempting to activate the dual-monitor treatment of SMIs and SMM) |
| 23 | VMXOFF under dual-monitor treatment of SMIs and SMM |
| 24 | VMCALL with invalid SMM-monitor features (when attempting to activate the dual-monitor treatment of SMIs and SMM) |
| 25 | VM entry with invalid VM-execution control fields in executive VMCS (when attempting to return from SMM)[2,3] |
| 26 | VM entry with events blocked by MOV SS. |
| 28 | Invalid operand to INVEPT/INVVPID. |

**NOTES:**

1. Earlier versions of this manual described this error as "VMRESUME with a corrupted VMCS".
2. VM-entry checks on control fields and host-state fields may be performed in any order. Thus, an indication by error number of one cause does not imply that there are not also other errors. Different processors may give different error numbers for the same VMCS.
3. Error number 7 is not used for VM entries that return from SMM that fail due to invalid VM-execution control fields in the executive VMCS. Error number 25 is used for these cases.

# CHAPTER 31
# VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

## 31.1 VMX SYSTEM PROGRAMMING OVERVIEW

The Virtual Machine Monitor (VMM) is a software class used to manage virtual machines (VM). This chapter describes programming considerations for VMMs.

Each VM behaves like a complete physical machine and can run operating system (OS) and applications. The VMM software layer runs at the most privileged level and has complete ownership of the underlying system hardware. The VMM controls creation of a VM, transfers control to a VM, and manages situations that can cause transitions between the guest VMs and host VMM. The VMM allows the VMs to share the underlying hardware and yet provides isolation between the VMs. The guest software executing in a VM is unaware of any transitions that might have occurred between the VM and its host.

## 31.2 SUPPORTING PROCESSOR OPERATING MODES IN GUEST ENVIRONMENTS

Typically, VMMs transfer control to a VM using VMX transitions referred to as VM entries. The boundary conditions that define what a VM is allowed to execute in isolation are specified in a virtual-machine control structure (VMCS).

As noted in Section 23.8, processors may fix certain bits in CR0 and CR4 to specific values and not support other values. The first processors to support VMX operation require that CR0.PE and CR0.PG be 1 in VMX operation. Thus, a VM entry is allowed only to guests with paging enabled that are in protected mode or in virtual-8086 mode. Guest execution in other processor operating modes need to be specially handled by the VMM.

One example of such a condition is guest execution in real-mode. A VMM could support guest real-mode execution using at least two approaches:

- By using a fast instruction set emulator in the VMM.
- By using the similarity between real-mode and virtual-8086 mode to support real-mode guest execution in a virtual-8086 container. The virtual-8086 container may be implemented as a virtual-8086 container task within a monitor that emulates real-mode guest state and instructions, or by running the guest VM as the virtual-8086 container (by entering the guest with RFLAGS.VM[1] set). Attempts by real-mode code to access privileged state outside the virtual-8086 container would trap to the VMM and would also need to be emulated.

Another example of such a condition is guest execution in protected mode with paging disabled. A VMM could support such guest execution by using "identity" page tables to emulate unpaged protected mode.

### 31.2.1 Using Unrestricted Guest Mode

Processors which support the "unrestricted guest" VM-execution control allow VM software to run in real-address mode and unpaged protected mode. Since these modes do not use paging, VMM software must virtualize guest memory using EPT.

Special notes for 64-bit VMM software using the 1-setting of the "unrestricted guest" VM-execution control:

- It is recommended that 64-bit VMM software use the 1-settings of the "load IA32_EFER" VM entry control and the "save IA32_EFER" VM-exit control. If VM entry is establishing CR0.PG=0 and if the "IA-32e mode guest" and "load IA32_EFER" VM entry controls are both 0, VM entry leaves IA32_EFER.LME unmodified (i.e., the host value will persist in the guest).
- It is not necessary for VMM software to track guest transitions into and out of IA-32e mode for the purpose of maintaining the correct setting of the "IA-32e mode guest" VM entry control. This is because VM exits on

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.).

processors supporting the 1-setting of the "unrestricted guest" VM-execution control save the (guest) value of IA32_EFER.LMA into the "IA-32e mode guest" VM entry control.

## 31.3 MANAGING VMCS REGIONS AND POINTERS

A VMM must observe necessary procedures when working with a VMCS, the associated VMCS pointer, and the VMCS region. It must also not assume the state of persistency for VMCS regions in memory or cache.

Before entering VMX operation, the host VMM allocates a VMXON region. A VMM can host several virtual machines and have many VMCSs active under its management. A unique VMCS region is required for each virtual machine; a VMXON region is required for the VMM itself.

A VMM determines the VMCS region size by reading IA32_VMX_BASIC MSR; it creates VMCS regions of this size using a 4-KByte-aligned area of physical memory. Each VMCS region needs to be initialized with a VMCS revision identifier (at byte offset 0) identical to the revision reported by the processor in the VMX capability MSR.

**NOTE**

Software must not read or write directly to the VMCS data region as the format is not architecturally defined. Consequently, Intel recommends that the VMM remove any linear-address mappings to VMCS regions before loading.

System software does not need to do special preparation to the VMXON region before entering into VMX operation. The address of the VMXON region for the VMM is provided as an operand to VMXON instruction. Once in VMX root operation, the VMM needs to prepare data fields in the VMCS that control the execution of a VM upon a VM entry. The VMM can make a VMCS the current VMCS by using the VMPTRLD instruction. VMCS data fields must be read or written only through VMREAD and VMWRITE commands respectively.

Every component of the VMCS is identified by a 32-bit encoding that is provided as an operand to VMREAD and VMWRITE. Appendix B provides the encodings. A VMM must properly initialize all fields in a VMCS before using the current VMCS for VM entry.

A VMCS is referred to as a controlling VMCS if it is the current VMCS on a logical processor in VMX non-root operation. A current VMCS for controlling a logical processor in VMX non-root operation may be referred to as a working VMCS if the logical processor is not in VMX non-root operation. The relationship of active, current (i.e. working) and controlling VMCS during VMX operation is shown in Figure 31-1.

**NOTE**

As noted in Section 24.1, the processor may optimize VMX operation by maintaining the state of an active VMCS (one for which VMPTRLD has been executed) on the processor. Before relinquishing control to other system software that may, without informing the VMM, remove power from the processor (e.g., for transitions to S3 or S4) or leave VMX operation, a VMM must VMCLEAR all active VMCSs. This ensures that all VMCS data cached by the processor are flushed to memory and that no other software can corrupt the current VMM's VMCS data. It is also recommended that the VMM execute VMXOFF after such executions of VMCLEAR.

The VMX capability MSR IA32_VMX_BASIC reports the memory type used by the processor for accessing a VMCS or any data structures referenced through pointers in the VMCS. Software must maintain the VMCS structures in cache-coherent memory. Software must always map the regions hosting the I/O bitmaps, MSR bitmaps, VM-exit MSR-store area, VM-exit MSR-load area, and VM-entry MSR-load area to the write-back (WB) memory type. Mapping these regions to uncacheable (UC) memory type is supported, but strongly discouraged due to negative impact on performance.

## 31.4 USING VMX INSTRUCTIONS

VMX instructions are allowed only in VMX root operation. An attempt to execute a VMX instruction in VMX non-root operation causes a VM exit.

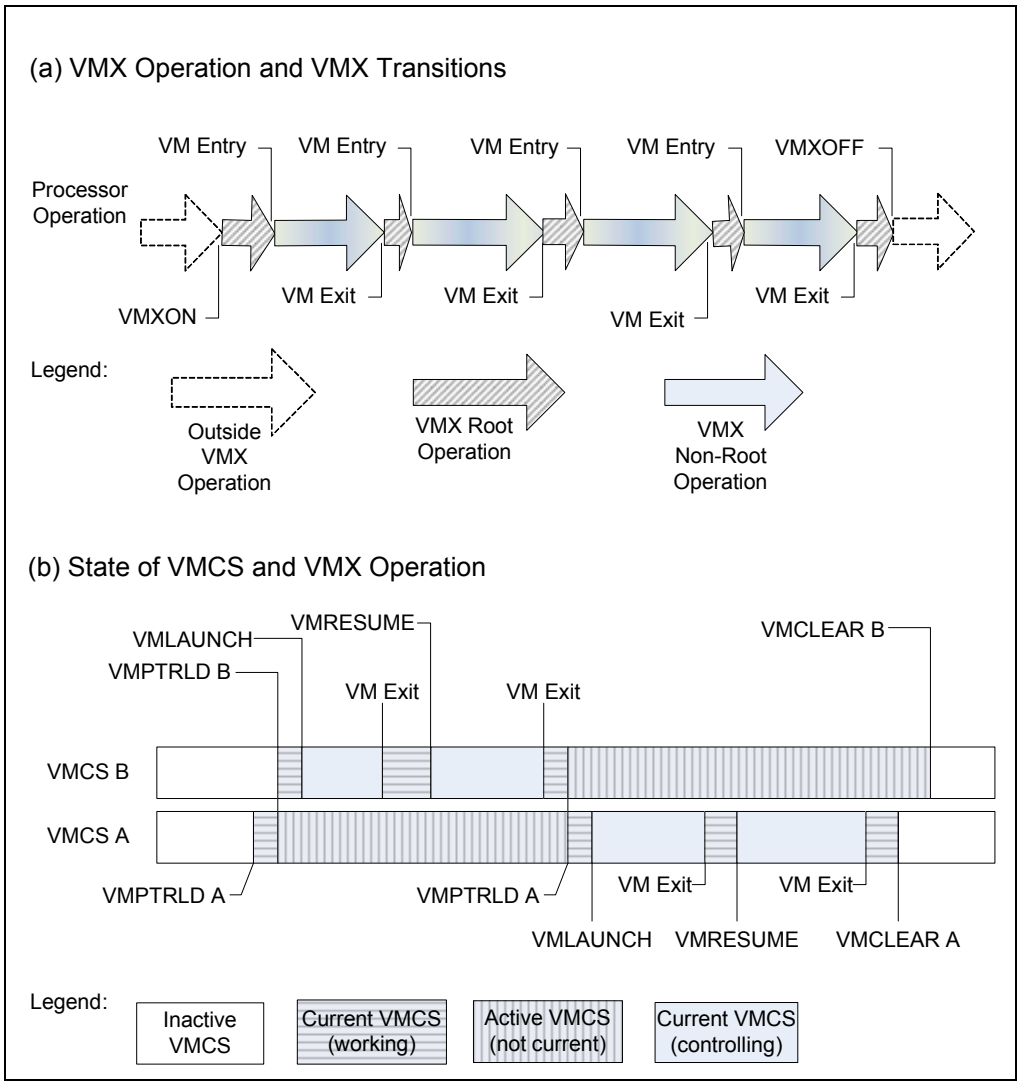

**Figure 31-1. VMX Transitions and States of VMCS in a Logical Processor**

Processors perform various checks while executing any VMX instruction. They follow well-defined error handling on failures. VMX instruction execution failures detected before loading of a guest state are handled by the processor as follows:

- If the working-VMCS pointer is not valid, the instruction fails by setting RFLAGS.CF to 1.
- If the working-VMCS pointer is valid, RFLAGS.ZF is set to 1 and the proper error-code is saved in the VM-instruction error field of the working-VMCS.

Software is required to check RFLAGS.CF and RFLAGS.ZF to determine the success or failure of VMX instruction executions.

The following items provide details regarding use of the VM-entry instructions (VMLAUNCH and VMRESUME):

- If the working-VMCS pointer is valid, the state of the working VMCS may cause the VM-entry instruction to fail. RFLAGS.ZF is set to 1 and one of the following values is saved in the VM-instruction error field:
  - 4: VMLAUNCH with non-clear VMCS.
    If this error occurs, software can avoid the error by executing VMRESUME.
  - 5: VMRESUME with non-launched VMCS.
    If this error occurs, software can avoid the error by executing VMLAUNCH.

— 6: VMRESUME after VMXOFF.[1]
If this error occurs, software can avoid the error by executing the following sequence of instructions:

```
VMPTRST ⟨working-VMCS pointer⟩
VMCLEAR ⟨working-VMCS pointer⟩
VMPTRLD ⟨working-VMCS pointer⟩
VMLAUNCH
```

(VMPTRST may not be necessary is software already knows the working-VMCS pointer.)

- If none of the above errors occur, the processor checks on the VMX controls and host-state area. If any of these checks fail, the VM-entry instruction fails. RFLAGS.ZF is set to 1 and either 7 (VM entry with invalid control field(s)) or 8 (VM entry with invalid host-state field(s)) is saved in the VM-instruction error field.
- After a VM-entry instruction (VMRESUME or VMLAUNCH) successfully completes the general checks and checks on VMX controls and the host-state area (see Section 26.2), any errors encountered while loading of guest-state (due to bad guest-state or bad MSR loading) causes the processor to load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 31.7).

  This failure behavior differs from that of VM exits in that no guest-state is saved to the guest-state area. A VMM can detect its VM-exit handler was invoked by such a failure by checking bit 31 (for 1) in the exit reason field of the working VMCS and further identify the failure by using the exit qualification field.

See Chapter 26 for more details about the VM-entry instructions.

## 31.5 VMM SETUP & TEAR DOWN

VMMs need to ensure that the processor is running in protected mode with paging before entering VMX operation. The following list describes the minimal steps required to enter VMX root operation with a VMM running at CPL = 0.

- Check VMX support in processor using CPUID.
- Determine the VMX capabilities supported by the processor through the VMX capability MSRs. See Section 31.5.1 and Appendix A.
- Create a VMXON region in non-pageable memory of a size specified by IA32_VMX_BASIC MSR and aligned to a 4-KByte boundary. Software should read the capability MSRs to determine width of the physical addresses that may be used for the VMXON region and ensure the entire VMXON region can be addressed by addresses with that width. Also, software must ensure that the VMXON region is hosted in cache-coherent memory.
- Initialize the version identifier in the VMXON region (the first 31 bits) with the VMCS revision identifier reported by capability MSRs. Clear bit 31 of the first 4 bytes of the VMXON region.
- Ensure the current processor operating mode meets the required CR0 fixed bits (CR0.PE = 1, CR0.PG = 1). Other required CR0 fixed bits can be detected through the IA32_VMX_CR0_FIXED0 and IA32_VMX_CR0_FIXED1 MSRs.
- Enable VMX operation by setting CR4.VMXE = 1. Ensure the resultant CR4 value supports all the CR4 fixed bits reported in the IA32_VMX_CR4_FIXED0 and IA32_VMX_CR4_FIXED1 MSRs.
- Ensure that the IA32_FEATURE_CONTROL MSR (MSR index 3AH) has been properly programmed and that its lock bit is set (Bit 0 = 1). This MSR is generally configured by the BIOS using WRMSR.
- Execute VMXON with the physical address of the VMXON region as the operand. Check successful execution of VMXON by checking if RFLAGS.CF = 0.

Upon successful execution of the steps above, the processor is in VMX root operation.

A VMM executing in VMX root operation and CPL = 0 leaves VMX operation by executing VMXOFF and verifies successful execution by checking if RFLAGS.CF = 0 and RFLAGS.ZF = 0.

If an SMM monitor has been configured to service SMIs while in VMX operation (see Section 34.15), the SMM monitor needs to be torn down before the executive monitor can leave VMX operation (see Section 34.15.7). VMXOFF fails for the executive monitor (a VMM that entered VMX operation by way of issuing VMXON) if SMM monitor is configured.

1. Earlier versions of this manual described this error as “VMRESUME with a corrupted VMCS”.

### 31.5.1 Algorithms for Determining VMX Capabilities

As noted earlier, a VMM should determine the VMX capabilities supported by the processor by reading the VMX capability MSRs. The architecture for these MSRs is detailed in Appendix A.

As noted in Chapter 26, "VM Entries", certain VMX controls are reserved and must be set to a specific value (0 or 1) determined by the processor. The specific value to which a reserved control must be set is its **default setting**. Most controls have a default setting of 0; Appendix A.2 identifies those controls that have a default setting of 1. The term **default1** describes the class of controls whose default setting is 1. The are controls in this class from the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls. There are no secondary processor-based VM-execution controls in the default1 class.

Future processors may define new functionality for one or more reserved controls. Such processors would allow each newly defined control to be set either to 0 or to 1. Software that does not desire a control's new functionality should set the control to its default setting.

The capability MSRs IA32_VMX_PINBASED_CTLS, IA32_VMX_PROCBASED_CTLS, IA32_VMX_EXIT_CTLS, and IA32_VMX_ENTRY_CTLS report, respectively, on the allowed settings of most of the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls. However, they will always report that any control in the default1 class must be 1. If a logical processor allows any control in the default1 class to be 0, it indicates this fact by returning 1 for the value of bit 55 of the IA32_VMX_BASIC MSR. If this bit is 1, the logical processor supports the capability MSRs IA32_VMX_TRUE_PINBASED_CTLS, IA32_VMX_TRUE_PROCBASED_CTLS, IA32_VMX_TRUE_EXIT_CTLS, and IA32_VMX_TRUE_ENTRY_CTLS. These capability MSRs report, respectively, on the allowed settings of all of the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls.

Software may use one of the following high-level algorithms to determine the correct default control settings:[1]

1. The following algorithm does not use the details given in Appendix A.2:
   a. Ignore bit 55 of the IA32_VMX_BASIC MSR.
   b. Using RDMSR, read the VMX capability MSRs IA32_VMX_PINBASED_CTLS, IA32_VMX_PROCBASED_CTLS, IA32_VMX_EXIT_CTLS, and IA32_VMX_ENTRY_CTLS.
   c. Set the VMX controls as follows:
      i) If the relevant VMX capability MSR reports that a control has a single setting, use that setting.
      ii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.
      iii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is not known to the VMM; then set the control to 0.

   A VMM using this algorithm will set to 1 all controls in the default1 class (in step (c)(i)). It will operate correctly even on processors that allow some controls in the default1 class to be 0. However, such a VMM will not be able to use the new features enabled by the 0-setting of such controls. For that reason, this algorithm is not recommended.
2. The following algorithm uses the details given in Appendix A.2. This algorithm requires software to know the identity of the controls in the default1 class:
   a. Using RDMSR, read the IA32_VMX_BASIC MSR.
   b. Use bit 55 of that MSR as follows:
      i) If bit 55 is 0, use RDMSR to read the VMX capability MSRs IA32_VMX_PINBASED_CTLS, IA32_VMX_PROCBASED_CTLS, IA32_VMX_EXIT_CTLS, and IA32_VMX_ENTRY_CTLS.
      ii) If bit 55 is 1, use RDMSR to read the VMX capability MSRs IA32_VMX_TRUE_PINBASED_CTLS, IA32_VMX_TRUE_PROCBASED_CTLS, IA32_VMX_TRUE_EXIT_CTLS, and IA32_VMX_TRUE_ENTRY_CTLS.

1. These algorithms apply only to the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls. Because there are no secondary processor-based VM-execution controls in the default1 class, a VMM can always set to 0 any such control whose meaning is unknown to it.

c. Set the VMX controls as follows:

i) If the relevant VMX capability MSR reports that a control has a single setting, use that setting.

ii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.

iii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the control is not in the default1 class; then set the control to 0.

iv) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the control is in the default1 class; then set the control to 1.

A VMM using this algorithm will set to 1 all controls in default1 class whose meaning it does not know (either in step (c)(i) or step (c)(iv)). It will operate correctly even on processors that allow some controls in the default1 class to be 0. Unlike a VMM using Algorithm 1, a VMM using Algorithm 2 will be able to use the new features enabled by the 0-setting of such controls.

3. The following algorithm uses the details given in Appendix A.2. This algorithm does not require software to know the identity of the controls in the default1 class:

a. Using RDMSR, read the VMX capability MSRs IA32_VMX_BASIC, IA32_VMX_PINBASED_CTLS, IA32_VMX_PROCBASED_CTLS, IA32_VMX_EXIT_CTLS, and IA32_VMX_ENTRY_CTLS.

b. If bit 55 of the IA32_VMX_BASIC MSR is 0, set the VMX controls as follows:

i) If the relevant VMX capability MSR reports that a control has a single setting, use that setting.

ii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.

iii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is not known to the VMM; then set the control to 0.

c. If bit 55 of the IA32_VMX_BASIC MSR is 1, use RDMSR to read the VMX capability MSRs IA32_VMX_TRUE_PINBASED_CTLS, IA32_VMX_TRUE_PROCBASED_CTLS, IA32_VMX_TRUE_EXIT_CTLS, and IA32_VMX_TRUE_ENTRY_CTLS. Set the VMX controls as follows:

i) If the relevant VMX capability MSR just read reports that a control has a single setting, use that setting.

ii) If (1) the relevant VMX capability MSR just read reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.

iii) If (1) the relevant VMX capability MSR just read reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the relevant VMX capability MSR as read in step (a) reports that a control can be set to 0; then set the control to 0.

iv) If (1) the relevant VMX capability MSR just read reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the relevant VMX capability MSR as read in step (a) reports that a control must be 1; then set the control to 1.

A VMM using this algorithm will set to 1 all controls in the default1 class whose meaning it does not know (in step (b)(i), step (c)(i), or step (c)(iv)). It will operate correctly even on processors that allow some controls in the default1 class to be 0. Unlike a VMM using Algorithm 1, a VMM using Algorithm 3 will be able to use the new features enabled by the 0-setting of such controls. Unlike a VMM using Algorithm 2, a VMM using Algorithm 3 need not know the identities of the controls in the default1 class.

## 31.6 PREPARATION AND LAUNCHING A VIRTUAL MACHINE

The following list describes the minimal steps required by the VMM to set up and launch a guest VM.

- Create a VMCS region in non-pageable memory of size specified by the VMX capability MSR IA32_VMX_BASIC and aligned to 4-KBytes. Software should read the capability MSRs to determine width of the physical addresses that may be used for a VMCS region and ensure the entire VMCS region can be addressed by

addresses with that width. The term "guest-VMCS address" refers to the physical address of the new VMCS region for the following steps.

- Initialize the version identifier in the VMCS (first 31 bits) with the VMCS revision identifier reported by the VMX capability MSR IA32_VMX_BASIC. Clear bit 31 of the first 4 bytes of the VMCS region.
- Execute the VMCLEAR instruction by supplying the guest-VMCS address. This will initialize the new VMCS region in memory and set the launch state of the VMCS to "clear". This action also invalidates the working-VMCS pointer register to FFFFFFFF_FFFFFFFFH. Software should verify successful execution of VMCLEAR by checking if RFLAGS.CF = 0 and RFLAGS.ZF = 0.
- Execute the VMPTRLD instruction by supplying the guest-VMCS address. This initializes the working-VMCS pointer with the new VMCS region's physical address.
- Issue a sequence of VMWRITEs to initialize various host-state area fields in the working VMCS. The initialization sets up the context and entry-points to the VMM upon subsequent VM exits from the guest. Host-state fields include control registers (CR0, CR3 and CR4), selector fields for the segment registers (CS, SS, DS, ES, FS, GS and TR), and base-address fields (for FS, GS, TR, GDTR and IDTR; RSP, RIP and the MSRs that control fast system calls).

  Chapter 27 describes the host-state consistency checking done by the processor for VM entries. The VMM is required to set up host-state that comply with these consistency checks. For example, VMX requires the host-area to have a task register (TR) selector with TI and RPL fields set to 0 and pointing to a valid TSS.
- Use VMWRITEs to set up the various VM-exit control fields, VM-entry control fields, and VM-execution control fields in the VMCS. Care should be taken to make sure the settings of individual fields match the allowed 0 and 1 settings for the respective controls as reported by the VMX capability MSRs (see Appendix A). Any settings inconsistent with the settings reported by the capability MSRs will cause VM entries to fail.
- Use VMWRITE to initialize various guest-state area fields in the working VMCS. This sets up the context and entry-point for guest execution upon VM entry. Chapter 27 describes the guest-state loading and checking done by the processor for VM entries to protected and virtual-8086 guest execution.
- The VMM is required to set up guest-state that complies with these consistency checks:
  - If the VMM design requires the initial VM launch to cause guest software (typically the guest virtual BIOS) execution from the guest's reset vector, it may need to initialize the guest execution state to reflect the state of a physical processor at power-on reset (described in Chapter 9, *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*).
  - The VMM may need to initialize additional guest execution state that is not captured in the VMCS guest-state area by loading them directly on the respective processor registers. Examples include general purpose registers, the CR2 control register, debug registers, floating point registers and so forth. VMM may support lazy loading of FPU, MMX, SSE, and SSE2 states with CR0.TS = 1 (described in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*).
- Execute VMLAUNCH to launch the guest VM. If VMLAUNCH fails due to any consistency checks before guest-state loading, RFLAGS.CF or RFLAGS.ZF will be set and the VM-instruction error field (see Section 24.9.5) will contain the error-code. If guest-state consistency checks fail upon guest-state loading, the processor loads state from the host-state area as if a VM exit had occurred (see Section 31.6).

VMLAUNCH updates the controlling-VMCS pointer with the working-VMCS pointer and saves the old value of controlling-VMCS as the parent pointer. In addition, the launch state of the guest VMCS is changed to "launched" from "clear". Any programmed exit conditions will cause the guest to VM exit to the VMM. The VMM should execute VMRESUME instruction for subsequent VM entries to guests in a "launched" state.

## 31.7 HANDLING OF VM EXITS

This section provides examples of software steps involved in a VMM's handling of VM-exit conditions:

- Determine the exit reason through a VMREAD of the exit-reason field in the working-VMCS. Appendix C describes exit reasons and their encodings.
- VMREAD the exit-qualification from the VMCS if the exit-reason field provides a valid qualification. The exit-qualification field provides additional details on the VM-exit condition. For example, in case of page faults, the exit-qualification field provides the guest linear address that caused the page fault.

- Depending on the exit reason, fetch other relevant fields from the VMCS. Appendix C lists the various exit reasons.
- Handle the VM-exit condition appropriately in the VMM. This may involve the VMM emulating one or more guest instructions, programming the underlying host hardware resources, and then re-entering the VM to continue execution.

## 31.7.1 Handling VM Exits Due to Exceptions

As noted in Section 25.2, an exception causes a VM exit if the bit corresponding to the exception's vector is set in the exception bitmap. (For page faults, the error code also determines whether a VM exit occurs.) This section provide some guidelines of how a VMM might handle such exceptions.

Exceptions result when a logical processor encounters an unusual condition that software may not have expected. When guest software encounters an exception, it may be the case that the condition was caused by the guest software. For example, a guest application may attempt to access a page that is restricted to supervisor access. Alternatively, the condition causing the exception may have been established by the VMM. For example, a guest OS may attempt to access a page that the VMM has chosen to make not present.

When the condition causing an exception was established by guest software, the VMM may choose to **reflect** the exception to guest software. When the condition was established by the VMM itself, the VMM may choose to **resume** guest software after removing the condition.

### 31.7.1.1 Reflecting Exceptions to Guest Software

If the VMM determines that a VM exit was caused by an exception due to a condition established by guest software, it may reflect that exception to guest software. The VMM would cause the exception to be delivered to guest software, where it can be handled as it would be if the guest were running on a physical machine. This section describes how that may be done.

In general, the VMM can deliver the exception to guest software using VM-entry event injection as described in Section 26.5. The VMM can copy (using VMREAD and VMWRITE) the contents of the VM-exit interruption-information field (which is valid, since the VM exit was caused by an exception) to the VM-entry interruption-information field (which, if valid, will cause the exception to be delivered as part of the next VM entry). The VMM would also copy the contents of the VM-exit interruption error-code field to the VM-entry exception error-code field; this need not be done if bit 11 (error code valid) is clear in the VM-exit interruption-information field. After this, the VMM can execute VMRESUME.

The following items provide details that may qualify the general approach:

- Care should be taken to ensure that reserved bits 30:12 in the VM-entry interruption-information field are 0. In particular, some VM exits may set bit 12 in the VM-exit interruption-information field to indicate NMI unblocking due to IRET. If this bit is copied as 1 into the VM-entry interruption-information field, the next VM entry will fail because that bit should be 0.
- Bit 31 (valid) of the IDT-vectoring information field indicates, if set, that the exception causing the VM exit occurred while another event was being delivered to guest software. If this is the case, it may not be appropriate simply to reflect that exception to guest software. To provide proper virtualization of the exception architecture, a VMM should handle nested events as a physical processor would. Processor handling is described in Chapter 6, "Interrupt 8—Double Fault Exception (#DF)" in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.
  - The VMM should reflect the exception causing the VM exit to guest software in any of the following cases:
    - The value of bits 10:8 (interruption type) of the IDT-vectoring information field is anything other than 3 (hardware exception).
    - The value of bits 7:0 (vector) of the IDT-vectoring information field indicates a benign exception (1, 2, 3, 4, 5, 6, 7, 9, 16, 17, 18, or 19).
    - The value of bits 7:0 (vector) of the VM-exit interruption-information field indicates a benign exception.

- The value of bits 7:0 of the IDT-vectoring information field indicates a contributory exception (0, 10, 11, 12, or 13) and the value of bits 7:0 of the VM-exit interruption-information field indicates a page fault (14).

— If the value of bits 10:8 of the IDT-vectoring information field is 3 (hardware exception), the VMM should reflect a double-fault exception to guest software in any of the following cases:

- The value of bits 7:0 of the IDT-vectoring information field and the value of bits 7:0 of the VM-exit interruption-information field each indicates a contributory exception.
- The value of bits 7:0 of the IDT-vectoring information field indicates a page fault and the value of bits 7:0 of the VM-exit interruption-information field indicates either a contributory exception or a page fault.

A VMM can reflect a double-fault exception to guest software by setting the VM-entry interruption-information and VM-entry exception error-code fields as follows:

- Set bits 7:0 (vector) of the VM-entry interruption-information field to 8 (#DF).
- Set bits 10:8 (interruption type) of the VM-entry interruption-information field to 3 (hardware exception).
- Set bit 11 (deliver error code) of the VM-entry interruption-information field to 1.
- Clear bits 30:12 (reserved) of VM-entry interruption-information field.
- Set bit 31 (valid) of VM-entry interruption-information field.
- Set the VM-entry exception error-code field to zero.

— If the value of bits 10:8 of the IDT-vectoring information field is 3 (hardware exception) and the value of bits 7:0 is 8 (#DF), guest software would have encountered a triple fault. Event injection should not be used in this case. The VMM may choose to terminate the guest, or it might choose to enter the guest in the shutdown activity state.

#### 31.7.1.2 Resuming Guest Software after Handling an Exception

If the VMM determines that a VM exit was caused by an exception due to a condition established by the VMM itself, it may choose to resume guest software after removing the condition. The approach for removing the condition may be specific to the VMM's software architecture. and algorithms This section describes how guest software may be resumed after removing the condition.

In general, the VMM can resume guest software simply by executing VMRESUME. The following items provide details of cases that may require special handling:

- If the "NMI exiting" VM-execution control is 0, bit 12 of the VM-exit interruption-information field indicates that the VM exit was due to a fault encountered during an execution of the IRET instruction that unblocked non-maskable interrupts (NMIs). In particular, it provides this indication if the following are both true:

  — Bit 31 (valid) in the IDT-vectoring information field is 0.

  — The value of bits 7:0 (vector) of the VM-exit interruption-information field is not 8 (the VM exit is not due to a double-fault exception).

  If both are true and bit 12 of the VM-exit interruption-information field is 1, NMIs were blocked before guest software executed the IRET instruction that caused the fault that caused the VM exit. The VMM should set bit 3 (blocking by NMI) in the interruptibility-state field (using VMREAD and VMWRITE) before resuming guest software.
- If the "virtual NMIs" VM-execution control is 1, bit 12 of the VM-exit interruption-information field indicates that the VM exit was due to a fault encountered during an execution of the IRET instruction that removed virtual-NMI blocking. In particular, it provides this indication if the following are both true:

  — Bit 31 (valid) in the IDT-vectoring information field is 0.

  — The value of bits 7:0 (vector) of the VM-exit interruption-information field is not 8 (the VM exit is not due to a double-fault exception).

  If both are true and bit 12 of the VM-exit interruption-information field is 1, there was virtual-NMI blocking before guest software executed the IRET instruction that caused the fault that caused the VM exit. The VMM

should set bit 3 (blocking by NMI) in the interruptibility-state field (using VMREAD and VMWRITE) before resuming guest software.

- Bit 31 (valid) of the IDT-vectoring information field indicates, if set, that the exception causing the VM exit occurred while another event was being delivered to guest software. The VMM should ensure that the other event is delivered when guest software is resumed. It can do so using the VM-entry event injection described in Section 26.5 and detailed in the following paragraphs:
  - The VMM can copy (using VMREAD and VMWRITE) the contents of the IDT-vectoring information field (which is presumed valid) to the VM-entry interruption-information field (which, if valid, will cause the exception to be delivered as part of the next VM entry).
    - The VMM should ensure that reserved bits 30:12 in the VM-entry interruption-information field are 0. In particular, the value of bit 12 in the IDT-vectoring information field is undefined after all VM exits. If this bit is copied as 1 into the VM-entry interruption-information field, the next VM entry will fail because the bit should be 0.
    - If the "virtual NMIs" VM-execution control is 1 and the value of bits 10:8 (interruption type) in the IDT-vectoring information field is 2 (indicating NMI), the VM exit occurred during delivery of an NMI that had been injected as part of the previous VM entry. In this case, bit 3 (blocking by NMI) will be 1 in the interruptibility-state field in the VMCS. The VMM should clear this bit; otherwise, the next VM entry will fail (see Section 26.3.1.5).
  - The VMM can also copy the contents of the IDT-vectoring error-code field to the VM-entry exception error-code field. This need not be done if bit 11 (error code valid) is clear in the IDT-vectoring information field.
  - The VMM can also copy the contents of the VM-exit instruction-length field to the VM-entry instruction-length field. This need be done only if bits 10:8 (interruption type) in the IDT-vectoring information field indicate either software interrupt, privileged software exception, or software exception.

## 31.8 MULTI-PROCESSOR CONSIDERATIONS

The most common VMM design will be the symmetric VMM. This type of VMM runs the same VMM binary on all logical processors. Like a symmetric operating system, the symmetric VMM is written to ensure all critical data is updated by only one processor at a time, IO devices are accessed sequentially, and so forth. Asymmetric VMM designs are possible. For example, an asymmetric VMM may run its scheduler on one processor and run just enough of the VMM on other processors to allow the correct execution of guest VMs. The remainder of this section focuses on the multi-processor considerations for a symmetric VMM.

A symmetric VMM design does not preclude asymmetry in its operations. For example, a symmetric VMM can support asymmetric allocation of logical processor resources to guests. Multiple logical processors can be brought into a single guest environment to support an MP-aware guest OS. Because an active VMCS can not control more than one logical processor simultaneously, a symmetric VMM must make copies of its VMCS to control the VM allocated to support an MP-aware guest OS. Care must be taken when accessing data structures shared between these VMCSs. See Section 31.8.4.

Although it may be easier to develop a VMM that assumes a fully-symmetric view of hardware capabilities (with all processors supporting the same processor feature sets, including the same revision of VMX), there are advantages in developing a VMM that comprehends different levels of VMX capability (reported by VMX capability MSRs). One possible advantage of such an approach could be that an existing software installation (VMM and guest software stack) could continue to run without requiring software upgrades to the VMM, when the software installation is upgraded to run on hardware with enhancements in the processor's VMX capabilities. Another advantage could be that a single software installation image, consisting of a VMM and guests, could be deployed to multiple hardware platforms with varying VMX capabilities. In such cases, the VMM could fall back to a common subset of VMX features supported by all VMX revisions, or choose to understand the asymmetry of the VMX capabilities and assign VMs accordingly.

This section outlines some of the considerations to keep in mind when developing an MP-aware VMM.

### 31.8.1 Initialization

Before enabling VMX, an MP-aware VMM must check to make sure that all processors in the system are compatible and support features required. This can be done by:

- Checking the CPUID on each logical processor to ensure VMX is supported and that the overall feature set of each logical processor is compatible.
- Checking VMCS revision identifiers on each logical processor.
- Checking each of the "allowed-1" or "allowed-0" fields of the VMX capability MSR's on each processor.

### 31.8.2 Moving a VMCS Between Processors

An MP-aware VMM is free to assign any logical processor to a VM. But for performance considerations, moving a guest VMCS to another logical processor is slower than resuming that guest VMCS on the same logical processor. Certain VMX performance features (such as caching of portions of the VMCS in the processor) are optimized for a guest VMCS that runs on the same logical processor.

The reasons are:

- To restart a guest on the same logical processor, a VMM can use VMRESUME. VMRESUME is expected to be faster than VMLAUNCH in general.
- To migrate a VMCS to another logical processor, a VMM must use the sequence of VMCLEAR, VMPTRLD and VMLAUNCH.
- Operations involving VMCLEAR can impact performance negatively. See Section 24.11.3.

A VMM scheduler should make an effort to schedule a guest VMCS to run on the logical processor where it last ran. Such a scheduler might also benefit from doing lazy VMCLEARs (that is: performing a VMCLEAR on a VMCS only when the scheduler knows the VMCS is being moved to a new logical processor). The remainder of this section describes the steps a VMM must take to move a VMCS from one processor to another.

A VMM must check the VMCS revision identifier in the VMX capability MSR IA32_VMX_BASIC to determine if the VMCS regions are identical between all logical processors. If the VMCS regions are identical (same revision ID) the following sequence can be used to move or copy the VMCS from one logical processor to another:

- Perform a VMCLEAR operation on the source logical processor. This ensures that all VMCS data that may be cached by the processor are flushed to memory.
- Copy the VMCS region from one memory location to another location. This is an optional step assuming the VMM wishes to relocate the VMCS or move the VMCS to another system.
- Perform a VMPTRLD of the physical address of VMCS region on the destination processor to establish its current VMCS pointer.

If the revision identifiers are different, each field must be copied to an intermediate structure using individual reads (VMREAD) from the source fields and writes (VMWRITE) to destination fields. Care must be taken on fields that are hard-wired to certain values on some processor implementations.

### 31.8.3 Paired Index-Data Registers

A VMM may need to virtualize hardware that is visible to software using paired index-data registers. Paired index-data register interfaces, such as those used in PCI (CF8, CFC), require special treatment in cases where a VM performing writes to these pairs can be moved during execution. In this case, the index (e.g. CF8) should be part of the virtualized state. If the VM is moved during execution, writes to the index should be redone so subsequent data reads/writes go to the right location.

### 31.8.4 External Data Structures

Certain fields in the VMCS point to external data structures (for example: the MSR bitmap, the I/O bitmaps). If a logical processor is in VMX non-root operation, none of the external structures referenced by that logical

processor's current VMCS should be modified by any logical processor or DMA. Before updating one of these structures, the VMM must ensure that no logical processor whose current VMCS references the structure is in VMX non-root operation.

If a VMM uses multiple VMCS with each VMCS using separate external structures, and these structures must be kept synchronized, the VMM must apply the same care to updating these structures.

### 31.8.5 CPUID Emulation

CPUID reports information that is used by OS and applications to detect hardware features. It also provides multi-threading/multi-core configuration information. For example, MP-aware OSs rely on data reported by CPUID to discover the topology of logical processors in a platform (see Section 8.9, "Programming Considerations for Hardware Multi-Threading Capable Processors," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*).

If a VMM is to support asymmetric allocation of logical processor resources to guest OSs that are MP aware, then the VMM must emulate CPUID for its guests. The emulation of CPUID by the VMM must ensure the guest's view of CPUID leaves are consistent with the logical processor allocation committed by the VMM to each guest OS.

## 31.9 32-BIT AND 64-BIT GUEST ENVIRONMENTS

For the most part, extensions provided by VMX to support virtualization are orthogonal to the extensions provided by Intel 64 architecture. There are considerations that impact VMM designs. These are described in the following subsections.

### 31.9.1 Operating Modes of Guest Environments

For Intel 64 processors, VMX operation supports host and guest environments that run in IA-32e mode or without IA-32e mode. VMX operation also supports host and guest environments on IA-32 processors.

A VMM entering VMX operation while IA-32e mode is active is considered to be an IA-32e mode host. A VMM entering VMX operation while IA-32e mode is not activated or not available is referred to as a 32-bit VMM. The type of guest operations such VMMs support are summarized in Table 31-1.

**Table 31-1. Operating Modes for Host and Guest Environments**

| Capability | Guest Operation in IA-32e mode | Guest Operation Not Requiring IA-32e Mode |
|---|---|---|
| IA-32e mode VMM | Yes | Yes |
| 32-bit VMM | Not supported | Yes |

A VM exit may occur to an IA-32e mode guest in either 64-bit sub-mode or compatibility sub-mode of IA-32e mode. VMMs may resume guests in either mode. The sub-mode in which an IA-32e mode guest resumes VMX non-root operation is determined by the attributes of the code segment which experienced the VM exit. If CS.L = 1, the guest is executing in 64-bit mode; if CS.L = 0, the guest is executing in compatibility mode (see Section 31.9.5).

Not all of an IA-32e mode VMM must run in 64-bit mode. While some parts of an IA-32e mode VMM must run in 64-bit mode, there are only a few restrictions preventing a VMM from executing in compatibility mode. The most notable restriction is that most VMX instructions cause exceptions when executed in compatibility mode.

### 31.9.2 Handling Widths of VMCS Fields

Individual VMCS control fields must be accessed using VMREAD or VMWRITE instructions. Outside of 64-Bit mode, VMREAD and VMWRITE operate on 32 bits of data. The widths of VMCS control fields may vary depending on whether a processor supports Intel 64 architecture.

Many VMCS fields are architected to extend transparently on processors supporting Intel 64 architecture (64 bits on processors that support Intel 64 architecture, 32 bits on processors that do not). Some VMCS fields are 64-bits wide regardless of whether the processor supports Intel 64 architecture or is in IA-32e mode.

#### 31.9.2.1 Natural-Width VMCS Fields

Many VMCS fields operate using natural width. Such fields return (on reads) and set (on writes) 32-bits when operating in 32-bit mode and 64-bits when operating in 64-bit mode. For the most part, these fields return the naturally expected data widths. The "Guest RIP" field in the VMCS guest-state area is an example of this type of field.

#### 31.9.2.2 64-Bit VMCS Fields

Unlike natural width fields, these fields are fixed to 64-bit width on all processors. When in 64-bit mode, reads of these fields return 64-bit wide data and writes to these fields write 64-bits. When outside of 64-bit mode, reads of these fields return the low 32-bits and writes to these fields write the low 32-bits and zero the upper 32-bits. Should a non-IA-32e mode host require access to the upper 32-bits of these fields, a separate VMCS encoding is used when issuing VMREAD/VMWRITE instructions.

The VMCS control field "MSR bitmap address" (which contains the physical address of a region of memory which specifies which MSR accesses should generate VM-exits) is an example of this type of field. Specifying encoding 00002004H to VMREAD returns the lower 32-bits to non-IA-32e mode hosts and returns 64-bits to 64-bit hosts. The separate encoding 00002005H returns only the upper 32-bits.

### 31.9.3 IA-32e Mode Hosts

An IA-32e mode host is required to support 64-bit guest environments. Because activating IA-32e mode currently requires that paging be disabled temporarily and VMX entry requires paging to be enabled, IA-32e mode must be enabled before entering VMX operation. For this reason, it is not possible to toggle in and out of IA-32e mode in a VMM.

Section 31.5 describes the steps required to launch a VMM. An IA-32e mode host is also required to set the "host address-space size" VMCS VM-exit control to 1. The value of this control is then loaded in the IA32_EFER.LME/LMA and CS.L bits on each VM exit. This establishes a 64-bit host environment as execution transfers to the VMM entry point. At a minimum, the entry point is required to be in a 64-bit code segment. Subsequently, the VMM can, if it chooses, switch to 32-bit compatibility mode on a code-segment basis (see Section 31.9.1). Note, however, that VMX instructions other than VMCALL and VMFUNC are not supported in compatibility mode; they generate an invalid opcode exception if used.

The following VMCS controls determine the value of IA32_EFER when a VM exit occurs: the "host address-space size" control (described above), the "load IA32_EFER" VM-exit control, the "VM-exit MSR-load count," and the "VM-exit MSR-load address" (see Section 27.3).

If the "load IA32_EFER" VM-exit control is 1, the value of the LME and LMA bits in the IA32_EFER field in the host-state area must be the value of the "host address-space size" VM-exit control.

The loading of IA32_EFER.LME/LMA and CS.L bits established by the "host address-space size" control precede any loading of the IA32_EFER MSR due from the VM-exit MSR-load area. If IA32_EFER is specified in the VM-exit MSR-load area, the value of the LME bit in the load image of IA32_EFER should match the setting of the "host address-space size" control. Otherwise the attempt to modify the LME bit (while paging is enabled) will lead to a VMX-abort. However, IA32_EFER.LMA is always set by the processor to equal IA32_EFER.LME & CR0.PG; the value specified for LMA in the load image of the IA32_EFER MSR is ignored. For these and performance reasons, VMM writers may choose to not use the VM-exit/entry MSR-load/save areas for IA32_EFER.

On a VMM teardown, VMX operation should be exited before deactivating IA-32e mode if the latter is required.

### 31.9.4 IA-32e Mode Guests

A 32-bit guest can be launched by either IA-32e-mode hosts or non-IA-32e-mode hosts. A 64-bit guests can only be launched by a IA-32e-mode host.

In addition to the steps outlined in Section 31.6, VMM writers need to:

- Set the "IA-32e-mode guest" VM-entry control to 1 in the VMCS to assure VM-entry (VMLAUNCH or VMRESUME) will establish a 64-bit (or 32-bit compatible) guest operating environment.
- Enable paging (CR0.PG) and PAE mode (CR4.PAE) to assure VM-entry to a 64-bit guest will succeed.
- Ensure that the host to be in IA-32e mode (the IA32_EFER.LMA must be set to 1) and the setting of the VM-exit "host address-space size" control bit in the VMCS must also be set to 1.

If each of the above conditions holds true, then VM-entry will copy the value of the VM-entry "IA-32e-mode guest" control bit into the guests IA32_EFER.LME bit, which will result in subsequent activation of IA-32e mode. If any of the above conditions is false, the VM-entry will fail and load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 26.7).

The following VMCS controls determine the value of IA32_EFER on a VM entry: the "IA-32e-mode guest" VM-entry control (described above), the "load IA32_EFER" VM-entry control, the "VM-entry MSR-load count," and the "VM-entry MSR-load address" (see Section 26.4).

If the "load IA32_EFER" VM-entry control is 1, the value of the LME and LMA bits in the IA32_EFER field in the guest-state area must be the value of the "IA-32e-mode guest" VM-entry control. Otherwise, the VM entry fails.

The loading of IA32_EFER.LME bit (described above) precedes any loading of the IA32_EFER MSR from the VM-entry MSR-load area of the VMCS. If loading of IA32_EFER is specified in the VM-entry MSR-load area, the value of the LME bit in the load image should be match the setting of the "IA-32e-mode guest" VM-entry control. Otherwise, the attempt to modify the LME bit (while paging is enabled) results in a failed VM entry. However, IA32_EFER.LMA is always set by the processor to equal IA32_EFER.LME & CR0.PG; the value specified for LMA in the load image of the IA32_EFER MSR is ignored. For these and performance reasons, VMM writers may choose to not use the VM-exit/entry MSR-load/save areas for IA32_EFER MSR.

Note that the VMM can control the processor's architectural state when transferring control to a VM. VMM writers may choose to launch guests in protected mode and subsequently allow the guest to activate IA-32e mode or they may allow guests to toggle in and out of IA-32e mode. In this case, the VMM should require VM exit on accesses to the IA32_EFER MSR to detect changes in the operating mode and modify the VM-entry "IA-32e-mode guest" control accordingly.

A VMM should save/restore the extended (full 64-bit) contents of the guest general-purpose registers, the new general-purpose registers (R8-R15) and the SIMD registers introduced in 64-bit mode should it need to modify these upon VM exit.

### 31.9.5 32-Bit Guests

To launch or resume a 32-bit guest, VMM writers can follow the steps outlined in Section 31.6, making sure that the "IA-32e-mode guest" VM-entry control bit is set to 0. Then the "IA-32e-mode guest" control bit is copied into the guest IA32_EFER.LME bit, establishing IA32_EFER.LMA as 0.

## 31.10 HANDLING MODEL SPECIFIC REGISTERS

Model specific registers (MSR) provide a wide range of functionality. They affect processor features, control the programming interfaces, or are used in conjunction with specific instructions. As part of processor virtualization, a VMM may wish to protect some or all MSR resources from direct guest access.

VMX operation provides the following features to virtualize processor MSRs.

### 31.10.1 Using VM-Execution Controls

Processor-based VM-execution controls provide two levels of support for handling guest access to processor MSRs using RDMSR and WRMSR:

- **MSR bitmaps**: In VMX implementations that support a 1-setting (see Appendix A) of the user-MSR-bitmaps execution control bit, MSR bitmaps can be used to provide flexibility in managing guest MSR accesses. The

MSR-bitmap-address in the guest VMCS can be programmed by VMM to point to a bitmap region which specifies VM-exit behavior when reading and writing individual MSRs.

MSR bitmaps form a 4-KByte region in physical memory and are required to be aligned to a 4-KByte boundary. The first 1-KByte region manages read control of MSRs in the range 00000000H-00001FFFH; the second 1-KByte region covers read control of MSR addresses in the range C0000000H-C0001FFFH. The bitmaps for write control of these MSRs are located in the 2-KByte region immediately following the read control bitmaps. While the MSR bitmap address is part of VMCS, the MSR bitmaps themselves are not. This implies MSR bitmaps are not accessible through VMREAD and VMWRITE instructions but rather by using ordinary memory writes. Also, they are not specially cached by the processor and may be placed in normal cache-coherent memory by the VMM.

When MSR bitmap addresses are properly programmed and the use-MSR-bitmap control (see Section 24.6.2) is set, the processor consults the associated bit in the appropriate bitmap on guest MSR accesses to the corresponding MSR and causes a VM exit if the bit in the bitmap is set. Otherwise, the access is permitted to proceed. This level of protection may be utilized by VMMs to selectively allow guest access to some MSRs while virtualizing others.

- **Default MSR protection**: If the use-MSR-bitmap control is not set, an attempt by a guest to access any MSR causes a VM exit. This also occurs for any attempt to access an MSR outside the ranges identified above (even if the use-MSR-bitmap control is set).

VM exits due to guest MSR accesses may be identified by the VMM through VM-exit reason codes. The MSR-read exit reason implies guest software attempted to read an MSR protected either by default or through MSR bitmaps. The MSR-write exit reason implies guest software attempting to write a MSR protected through the VM-execution controls. Upon VM exits caused by MSR accesses, the VMM may virtualize the guest MSR access through emulation of RDMSR/WRMSR.

## 31.10.2 Using VM-Exit Controls for MSRs

If a VMM allows its guest to access MSRs directly, the VMM may need to store guest MSR values and load host MSR values for these MSRs on VM exits. This is especially true if the VMM uses the same MSRs while in VMX root operation.

A VMM can use the VM-exit MSR-store-address and the VM-exit MSR-store-count exit control fields (see Section 24.7.2) to manage how MSRs are stored on VM exits. The VM-exit MSR-store-address field contains the physical address (16-byte aligned) of the VM-exit MSR-store area (a table of entries with 16 bytes per entry). Each table entry specifies an MSR whose value needs to be stored on VM exits. The VM-exit MSR-store-count contains the number of entries in the table.

Similarly the VM-exit MSR-load-address and VM-exit MSR-load-count fields point to the location and size of the VM-exit MSR load area. The entries in the VM-exit MSR-load area contain the host expected values of specific MSRs when a VM exit occurs.

Upon VM-exit, bits 127:64 of each entry in the VM-exit MSR-store area is updated with the contents of the MSR indexed by bits 31:0. Also, bits 127:64 of each entry in the VM-exit MSR-load area is updated by loading with values from bits 127:64 the contents of the MSR indexed by bits 31:0.

## 31.10.3 Using VM-Entry Controls for MSRs

A VMM may require specific MSRs to be loaded explicitly on VM entries while launching or resuming guest execution. The VM-entry MSR-load-address and VM-entry MSR-load-count entry control fields determine how MSRs are loaded on VM-entries. The VM-entry MSR-load-address and count fields are similar in structure and function to the VM-exit MSR-load address and count fields, except the MSR loading is done on VM-entries.

## 31.10.4 Handling Special-Case MSRs and Instructions

A number of instructions make use of designated MSRs in their operation. The VMM may need to consider saving the states of those MSRs. Instructions that merit such consideration include SYSENTER/SYSEXIT, SYSCALL/SYSRET, SWAPGS.

### 31.10.4.1 Handling IA32_EFER MSR

The IA32_EFER MSR includes bit fields that allow system software to enable processor features. For example: the SCE bit enables SYSCALL/SYSRET and the NXE bit enables the execute-disable bits in the paging-structure entries.

VMX provides hardware support to load the IA32_EFER MSR on VMX transitions and to save it on VM exits. Because of this, VMM software need not use the RDMSR and WRMSR instruction to give the register different values during host and guest execution.

### 31.10.4.2 Handling the SYSENTER and SYSEXIT Instructions

The SYSENTER and SYSEXIT instructions use three dedicated MSRs (IA32_SYSENTER_CS, IA32_SYSENTER_ESP and IA32_SYSENTER_EIP) to manage fast system calls. These MSRs may be utilized by both the VMM and the guest OS to manage system calls in VMX root operation and VMX non-root operation respectively.

VM entries load these MSRs from fields in the guest-state area of the VMCS. VM exits save the values of these MSRs into those fields and loads the MSRs from fields in the host-state area.

### 31.10.4.3 Handling the SYSCALL and SYSRET Instructions

The SYSCALL/SYSRET instructions are similar to SYSENTER/SYSEXIT but are designed to operate within the context of a 64-bit flat code segment. They are available only in 64-bit mode and only when the SCE bit of the IA32_EFER MSR is set. SYSCALL/SYSRET invocations can occur from either 32-bit compatibility mode application code or from 64-bit application code. Three related MSR registers (IA32_STAR, IA32_LSTAR, IA32_FMASK) are used in conjunction with fast system calls/returns that use these instructions.

64-Bit hosts which make use of these instructions in the VMM environment will need to save the guest state of the above registers on VM exit, load the host state, and restore the guest state on VM entry. One possible approach is to use the VM-exit MSR-save and MSR-load areas and the VM-entry MSR-load area defined by controls in the VMCS. A disadvantage to this approach, however, is that the approach results in the unconditional saving, loading, and restoring of MSR registers on each VM exit or VM entry.

Depending on the design of the VMM, it is likely that many VM-exits will require no fast system call support but the VMM will be burdened with the additional overhead of saving and restoring MSRs if the VMM chooses to support fast system call uniformly. Further, even if the host intends to support fast system calls during a VM-exit, some of the MSR values (such as the setting of the SCE bit in IA32_EFER) may not require modification as they may already be set to the appropriate value in the guest.

For performance reasons, a VMM may perform lazy save, load, and restore of these MSR values on certain VM exits when it is determined that this is acceptable. The lazy-save-load-restore operation can be carried out "manually" using RDMSR and WRMSR.

### 31.10.4.4 Handling the SWAPGS Instruction

The SWAPGS instruction is available only in 64-bit mode. It swaps the contents of two specific MSRs (IA32_GSBASE and IA32_KERNEL_GSBASE). The IA32_GSBASE MSR shadows the base address portion of the GS descriptor register; the IA32_KERNEL_GSBASE MSR holds the base address of the GS segment used by the kernel (typically it houses kernel structures). SWAPGS is intended for use with fast system calls when in 64-bit mode to allow immediate access to kernel structures on transition to kernel mode.

Similar to SYSCALL/SYSRET, IA-32e mode hosts which use fast system calls may need to save, load, and restore these MSR registers on VM exit and VM entry using the guidelines discussed in previous paragraphs.

### 31.10.4.5 Implementation Specific Behavior on Writing to Certain MSRs

As noted in Section 26.4 and Section 27.4, a processor may prevent writing to certain MSRs when loading guest states on VM entries or storing guest states on VM exits. This is done to ensure consistent operation. The subset and number of MSRs subject to restrictions are implementation specific. For initial VMX implementations, there are two MSRs: IA32_BIOS_UPDT_TRIG and IA32_BIOS_SIGN_ID (see Chapter 35).

### 31.10.5 Handling Accesses to Reserved MSR Addresses

Privileged software (either a VMM or a guest OS) can access a model specific register by specifying addresses in MSR address space. VMMs, however, must prevent a guest from accessing reserved MSR addresses in MSR address space.

Consult Chapter 35 for lists of supported MSRs and their usage. Use the MSR bitmap control to cause a VM exit when a guest attempts to access a reserved MSR address. The response to such a VM exit should be to reflect #GP(0) back to the guest.

## 31.11 HANDLING ACCESSES TO CONTROL REGISTERS

Bit fields in control registers (CR0, CR4) control various aspects of processor operation. The VMM must prevent guests from modifying bits in CR0 or CR4 that are reserved at the time the VMM is written.

Guest/host masks should be used by the VMM to cause VM exits when a guest attempts to modify reserved bits. Read shadows should be used to ensure that the guest always reads the reserved value (usually 0) for such bits. The VMM response to VM exits due to attempts from a guest to modify reserved bits should be to emulate the response which the processor would have normally produced (usually a #GP(0)).

## 31.12 PERFORMANCE CONSIDERATIONS

VMX provides hardware features that may be used for improving processor virtualization performance. VMMs must be designed to use this support properly. The basic idea behind most of these performance optimizations of the VMM is to reduce the number of VM exits while executing a guest VM.

This section lists ways that VMMs can take advantage of the performance enhancing features in VMX.

- **Read Access to Control Registers.** Analysis of common client workloads with common PC operating systems in a virtual machine shows a large number of VM-exits are caused by control register read accesses (particularly CR0). Reads of CR0 and CR4 does not cause VM exits. Instead, they return values from the CR0/CR4 read-shadows configured by the VMM in the guest controlling-VMCS with the guest-expected values.
- **Write Access to Control Registers.** Most VMM designs require only certain bits of the control registers to be protected from direct guest access. Write access to CR0/CR4 registers can be reduced by defining the host-owned and guest-owned bits in them through the CR0/CR4 host/guest masks in the VMCS. CR0/CR4 write values by the guest are qualified with the mask bits. If they change only guest-owned bits, they are allowed without causing VM exits. Any write that cause changes to host-owned bits cause VM exits and need to be handled by the VMM.
- **Access Rights based Page Table protection.** For VMM that implement access-rights-based page table protection, the VMCS provides a CR3 target value list that can be consulted by the processor to determine if a VM exit is required. Loading of CR3 with a value matching an entry in the CR3 target-list are allowed to proceed without VM exits. The VMM can utilize the CR3 target-list to save page-table hierarchies whose state is previously verified by the VMM.
- **Page-fault handling.** Another common cause for a VM exit is due to page-faults induced by guest address remapping done through virtual memory virtualization. VMX provides page-fault error-code mask and match fields in the VMCS to filter VM exits due to page-faults based on their cause (reflected in the error-code).

## 31.13 USE OF THE VMX-PREEMPTION TIMER

The VMX-preemption timer allows VMM software to preempt guest VM execution after a specified amount of time. Typical VMX-preemption timer usage is to program the initial VM quantum into the timer, save the timer value on each successive VM-exit (using the VM-exit control “save preemption timer value”) and run the VM until the timer expires.

In an alternative scenario, the VMM may use another timer (e.g. the TSC) to track the amount of time the VM has run while still using the VMX-preemption timer for VM preemption. In this scenario the VMM would not save the

VMX-preemption timer on each VM-exit but instead would reload the VMX-preemption timer with initial VM quantum less the time the VM has already run. This scenario includes all the VM-entry and VM-exit latencies in the VM run time.

In both scenarios, on each successive VM-entry the VMX-preemption timer contains a smaller value until the VM quantum ends. If the VMX-preemption timer is loaded with a value smaller than the VM-entry latency then the VM will not execute any instructions before the timer expires. The VMM must ensure the initial VM quantum is greater than the VM-entry latency; otherwise the VM will make no forward progress.

# CHAPTER 32
# VIRTUALIZATION OF SYSTEM RESOURCES

## 32.1 OVERVIEW

When a VMM is hosting multiple guest environments (VMs), it must monitor potential interactions between software components using the same system resources. These interactions can require the virtualization of resources. This chapter describes the virtualization of system resources. These include: debugging facilities, address translation, physical memory, and microcode update facilities.

## 32.2 VIRTUALIZATION SUPPORT FOR DEBUGGING FACILITIES

The Intel 64 and IA-32 debugging facilities (see Chapter 17) provide breakpoint instructions, exception conditions, register flags, debug registers, control registers and storage buffers for functions related to debugging system and application software. In VMX operation, a VMM can support debugging system and application software from within virtual machines if the VMM properly virtualizes debugging facilities. The following list describes features relevant to virtualizing these facilities.

- The VMM can program the exception-bitmap (see Section 24.6.3) to ensure it gets control on debug functions (like breakpoint exceptions occurring while executing guest code such as INT3 instructions). Normally, debug exceptions modify debug registers (such as DR6, DR7, IA32_DEBUGCTL). However, if debug exceptions cause VM exits, exiting occurs before register modification.
- The VMM may utilize the VM-entry event injection facilities described in Section 26.5 to inject debug or breakpoint exceptions to the guest. See Section 32.2.1 for a more detailed discussion.
- The MOV-DR exiting control bit in the processor-based VM-execution control field (see Section 24.6.2) can be enabled by the VMM to cause VM exits on explicit guest access of various processor debug registers (for example, MOV to/from DR0-DR7). These exits would always occur on guest access of DR0-DR7 registers regardless of the values in CPL, DR4.DE or DR7.GD. Since all guest task switches cause VM exits, a VMM can control any indirect guest access or modification of debug registers during guest task switches.
- Guest software access to debug-related model-specific registers (such as IA32_DEBUGCTL MSR) can be trapped by the VMM through MSR access control features (such as the MSR-bitmaps that are part of processor-based VM-execution controls). See Section 31.10 for details on MSR virtualization.
- Debug registers such as DR7 and the IA32_DEBUGCTL MSR may be explicitly modified by the guest (through MOV-DR or WRMSR instructions) or modified implicitly by the processor as part of generating debug exceptions. The current values of DR7 and the IA32_DEBUGCTL MSR are saved to guest-state area of VMCS on every VM exit. Pending debug exceptions are debug exceptions that are recognized by the processor but not yet delivered. See Section 26.6.3 for details on pending debug exceptions.
- DR7 and the IA32-DEBUGCTL MSR are loaded from values in the guest-state area of the VMCS on every VM entry. This allows the VMM to properly virtualize debug registers when injecting debug exceptions to guest. Similarly, the RFLAGS[1] register is loaded on every VM entry (or pushed to stack if injecting a virtual event) from guest-state area of the VMCS. Pending debug exceptions are also loaded from guest-state area of VMCS so that they may be delivered after VM entry is completed.

### 32.2.1 Debug Exceptions

If a VMM emulates a guest instruction that would encounter a debug trap (single step or data or I/O breakpoint), it should cause that trap to be delivered. The VMM should not inject the debug exception using VM-entry event injection, but should set the appropriate bits in the pending debug exceptions field. This method will give the trap the

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.).

right priority with respect to other events. (If the exception bitmap was programmed to cause VM exits on debug exceptions, the debug trap will cause a VM exit. At this point, the trap can be injected during VM entry with the proper priority.)

There is a valid pending debug exception if the BS bit (see Table 24-4) is set, regardless of the values of RFLAGS.TF or IA32_DEBUGCTL.BTF. The values of these bits do not impact the delivery of pending debug exceptions.

VMMs should exercise care when emulating a guest write (attempted using WRMSR) to IA32_DEBUGCTL to modify BTF if this is occurring with RFLAGS.TF = 1 and after a MOV SS or POP SS instruction (for example: while debug exceptions are blocked). Note the following:

- Normally, if WRMSR clears BTF while RFLAGS.TF = 1 and with debug exceptions blocked, a single-step trap will occur after WRMSR. A VMM emulating such an instruction should set the BS bit (see Table 24-4) in the pending debug exceptions field before VM entry.
- Normally, if WRMSR sets BTF while RFLAGS.TF = 1 and with debug exceptions blocked, neither a single-step trap nor a taken-branch trap can occur after WRMSR. A VMM emulating such an instruction should clear the BS bit (see Table 24-4) in the pending debug exceptions field before VM entry.

## 32.3 MEMORY VIRTUALIZATION

VMMs must control physical memory to ensure VM isolation and to remap guest physical addresses in host physical address space for virtualization. Memory virtualization allows the VMM to enforce control of physical memory and yet support guest OSs' expectation to manage memory address translation.

### 32.3.1 Processor Operating Modes & Memory Virtualization

Memory virtualization is required to support guest execution in various processor operating modes. This includes: protected mode with paging, protected mode with no paging, real-mode and any other transient execution modes. VMX allows guest operation in protected-mode with paging enabled and in virtual-8086 mode (with paging enabled) to support guest real-mode execution. Guest execution in transient operating modes (such as in real mode with one or more segment limits greater than 64-KByte) must be emulated by the VMM.

Since VMX operation requires processor execution in protected mode with paging (through CR0 and CR4 fixed bits), the VMM may utilize paging structures to support memory virtualization. To support guest real-mode execution, the VMM may establish a simple flat page table for guest linear to host physical address mapping. Memory virtualization algorithms may also need to capture other guest operating conditions (such as guest performing A20M# address masking) to map the resulting 20-bit effective guest physical addresses.

### 32.3.2 Guest & Host Physical Address Spaces

Memory virtualization provides guest software with contiguous guest physical address space starting zero and extending to the maximum address supported by the guest virtual processor's physical address width. The VMM utilizes guest physical to host physical address mapping to locate all or portions of the guest physical address space in host memory. The VMM is responsible for the policies and algorithms for this mapping which may take into account the host system physical memory map and the virtualized physical memory map exposed to a guest by the VMM. The memory virtualization algorithm needs to accommodate various guest memory uses (such as: accessing DRAM, accessing memory-mapped registers of virtual devices or core logic functions and so forth). For example:

- To support guest DRAM access, the VMM needs to map DRAM-backed guest physical addresses to host-DRAM regions. The VMM also requires the guest to host memory mapping to be at page granularity.
- Virtual devices (I/O devices or platform core logic) emulated by the VMM may claim specific regions in the guest physical address space to locate memory-mapped registers. Guest access to these virtual registers may be configured to cause page-fault induced VM-exits by marking these regions as always not present. The VMM may handle these VM exits by invoking appropriate virtual device emulation code.

### 32.3.3 Virtualizing Virtual Memory by Brute Force

VMX provides the hardware features required to fully virtualize guest virtual memory accesses. VMX allows the VMM to trap guest accesses to the PAT (Page Attribute Table) MSR and the MTRR (Memory Type Range Registers). This control allows the VMM to virtualize the specific memory type of a guest memory. The VMM may control caching by controlling the guest CR0.CRD and CR0.NW bits, as well as by trapping guest execution of the INVD instruction. The VMM can trap guest CR3 loads and stores, and it may trap guest execution of INVLPG.

Because a VMM must retain control of physical memory, it must also retain control over the processor's address-translation mechanisms. Specifically, this means that only the VMM can access CR3 (which contains the base of the page directory) and can execute INVLPG (the only other instruction that directly manipulates the TLB).

At the same time that the VMM controls address translation, a guest operating system will also expect to perform normal memory management functions. It will access CR3, execute INVLPG, and modify (what it believes to be) page directories and page tables. Virtualization of address translation must tolerate and support guest attempts to control address translation.

A simple-minded way to do this would be to ensure that all guest attempts to access address-translation hardware trap to the VMM where such operations can be properly emulated. It must ensure that accesses to page directories and page tables also get trapped. This may be done by protecting these in-memory structures with conventional page-based protection. The VMM can do this because it can locate the page directory because its base address is in CR3 and the VMM receives control on any change to CR3; it can locate the page tables because their base addresses are in the page directory.

Such a straightforward approach is not necessarily desirable. Protection of the in-memory translation structures may be cumbersome. The VMM may maintain these structures with different values (e.g., different page base addresses) than guest software. This means that there must be traps on guest attempt to read these structures and that the VMM must maintain, in auxiliary data structures, the values to return to these reads. There must also be traps on modifications to these structures even if the translations they effect are never used. All this implies considerable overhead that should be avoided.

### 32.3.4 Alternate Approach to Memory Virtualization

Guest software is allowed to freely modify the guest page-table hierarchy without causing traps to the VMM. Because of this, the active page-table hierarchy might not always be consistent with the guest hierarchy. Any potential problems arising from inconsistencies can be solved using techniques analogous to those used by the processor and its TLB.

This section describes an alternative approach that allows guest software to freely access page directories and page tables. Traps occur on CR3 accesses and executions of INVLPG. They also occur when necessary to ensure that guest modifications to the translation structures actually take effect. The software mechanisms to support this approach are collectively called virtual TLB. This is because they emulate the functionality of the processor's physical translation look-aside buffer (TLB).

The basic idea behind the virtual TLB is similar to that behind the processor TLB. While the page-table hierarchy defines the relationship between physical to linear address, it does not directly control the address translation of each memory access. Instead, translation is controlled by the TLB, which is occasionally filled by the processor with translations derived from the page-table hierarchy. With a virtual TLB, the page-table hierarchy established by guest software (specifically, the guest operating system) does not control translation, either directly or indirectly. Instead, translation is controlled by the processor (through its TLB) and by the VMM (through a page-table hierarchy that it maintains).

Specifically, the VMM maintains an alternative page-table hierarchy that effectively caches translations derived from the hierarchy maintained by guest software. The remainder of this document refers to the former as the active page-table hierarchy (because it is referenced by CR3 and may be used by the processor to load its TLB) and the latter as the guest page-table hierarchy (because it is maintained by guest software). The entries in the active hierarchy may resemble the corresponding entries in the guest hierarchy in some ways and may differ in others.

Guest software is allowed to freely modify the guest page-table hierarchy without causing VM exits to the VMM. Because of this, the active page-table hierarchy might not always be consistent with the guest hierarchy. Any potential problems arising from any inconsistencies can be solved using techniques analogous to those used by the processor and its TLB. Note the following:

- Suppose the guest page-table hierarchy allows more access than active hierarchy (for example: there is a translation for a linear address in the guest hierarchy but not in the active hierarchy); this is analogous to a situation in which the TLB allows less access than the page-table hierarchy. If an access occurs that would be allowed by the guest hierarchy but not the active one, a page fault occurs; this is analogous to a TLB miss. The VMM gains control (as it handles all page faults) and can update the active page-table hierarchy appropriately; this corresponds to a TLB fill.
- Suppose the guest page-table hierarchy allows less access than the active hierarchy; this is analogous to a situation in which the TLB allows more access than the page-table hierarchy. This situation can occur only if the guest operating system has modified a page-table entry to reduce access (for example: by marking it not-present). Because the older, more permissive translation may have been cached in the TLB, the processor is architecturally permitted to use the older translation and allow more access. Thus, the VMM may (through the active page-table hierarchy) also allow greater access. For the new, less permissive translation to take effect, guest software should flush any older translations from the TLB either by executing INVLPG or by loading CR3. Because both these operations will cause a trap to the VMM, the VMM will gain control and can remove from the active page-table hierarchy the translations indicated by guest software (the translation of a specific linear address for INVLPG or all translations for a load of CR3).

As noted previously, the processor reads the page-table hierarchy to cache translations in the TLB. It also writes to the hierarchy to main the accessed (A) and dirty (D) bits in the PDEs and PTEs. The virtual TLB emulates this behavior as follows:

- When a page is accessed by guest software, the A bit in the corresponding PTE (or PDE for a 4-MByte page) in the active page-table hierarchy will be set by the processor (the same is true for PDEs when active page tables are accessed by the processor). For guest software to operate properly, the VMM should update the A bit in the guest entry at this time. It can do this reliably if it keeps the active PTE (or PDE) marked not-present until it has set the A bit in the guest entry.
- When a page is written by guest software, the D bit in the corresponding PTE (or PDE for a 4-MByte page) in the active page-table hierarchy will be set by the processor. For guest software to operate properly, the VMM should update the D bit in the guest entry at this time. It can do this reliably if it keeps the active PTE (or PDE) marked read-only until it has set the D bit in the guest entry. This solution is valid for guest software running at privilege level 3; support for more privileged guest software is described in Section 32.3.5.

### 32.3.5 Details of Virtual TLB Operation

This section describes in more detail how a VMM could support a virtual TLB. It explains how an active page-table hierarchy is initialized and how it is maintained in response to page faults, uses of INVLPG, and accesses to CR3. The mechanisms described here are the minimum necessary. They may not result in the best performance.

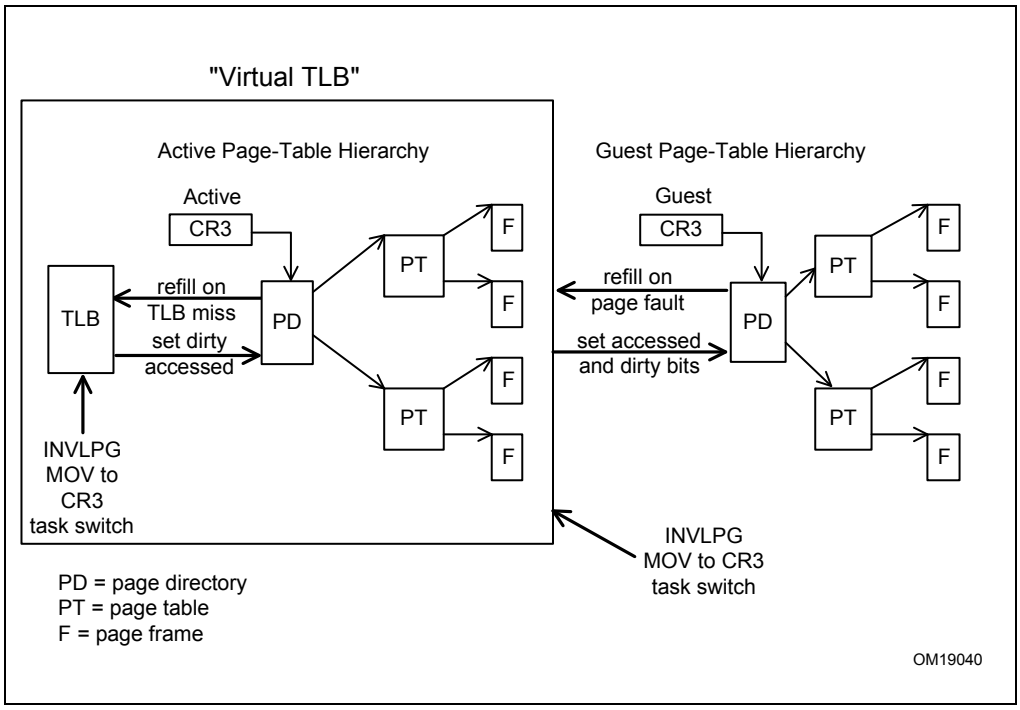

Figure 32-1. Virtual TLB Scheme

As noted above, the VMM maintains an active page-table hierarchy for each virtual machine that it supports. It also maintains, for each machine, values that the machine expects for control registers CR0, CR2, CR3, and CR4 (they control address translation). These values are called the guest control registers.

In general, the VMM selects the physical-address space that is allocated to guest software. The term guest address refers to an address installed by guest software in the guest CR3, in a guest PDE (as a page table base address or a page base address), or in a guest PTE (as a page base address). While guest software considers these to be specific physical addresses, the VMM may map them differently.

### 32.3.5.1 Initialization of Virtual TLB

To enable the Virtual TLB scheme, the VMCS must be set up to trigger VM exits on:

- All writes to CR3 (the CR3-target count should be 0) or the paging-mode bits in CR0 and CR4 (using the CR0 and CR4 guest/host masks)
- Page-fault (#PF) exceptions
- Execution of INVLPG

When guest software first enables paging, the VMM creates an aligned 4-KByte active page directory that is invalid (all entries marked not-present). This invalid directory is analogous to an empty TLB.

### 32.3.5.2 Response to Page Faults

Page faults can occur for a variety of reasons. In some cases, the page fault alerts the VMM to an inconsistency between the active and guest page-table hierarchy. In such cases, the VMM can update the former and re-execute the faulting instruction. In other cases, the hierarchies are already consistent and the fault should be handled by the guest operating system. The VMM can detect this and use an established mechanism for raising a page fault to guest software.

The VMM can handle a page fault by following these steps (The steps below assume the guest is operating in a paging mode without PAE. Analogous steps to handle address translation using PAE or four-level paging mecha-

nisms can be derived by VMM developers according to the paging behavior defined in Chapter 3 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*):

1. First consult the active PDE, which can be located using the upper 10 bits of the faulting address and the current value of CR3. The active PDE is the source of the fault if it is marked not present or if its R/W bit and U/S bits are inconsistent with the attempted guest access (the guest privilege level and the values of CR0.WP and CR4.SMEP should also be taken into account).
2. If the active PDE is the source of the fault, consult the corresponding guest PDE using the same 10 bits from the faulting address and the physical address that corresponds to the guest address in the guest CR3. If the guest PDE would cause a page fault (for example: it is marked not present), then raise a page fault to the guest operating system.

   The following steps assume that the guest PDE would not have caused a page fault.
3. If the active PDE is the source of the fault and the guest PDE contains, as page-table base address (if PS = 0) or page base address (PS = 1), a guest address that the VMM has chosen not to support; then raise a machine check (or some other abort) to the guest operating system.

   The following steps assume that the guest address in the guest PDE is supported for the virtual machine.
4. If the active PDE is marked not-present, then set the active PDE to correspond to guest PDE as follows:
   a. If the active PDE contains a page-table base address (if PS = 0), then allocate an aligned 4-KByte active page table marked completely invalid and set the page-table base address in the active PDE to be the physical address of the newly allocated page table.
   b. If the active PDE contains a page base address (if PS = 1), then set the page base address in the active PDE to be the physical page base address that corresponds to the guest address in the guest PDE.
   c. Set the P, U/S, and PS bits in the active PDE to be identical to those in the guest PDE.
   d. Set the PWT, PCD, and G bits according to the policy of the VMM.
   e. Set A = 1 in the guest PDE.
   f. If D = 1 in the guest PDE or PS = 0 (meaning that this PDE refers to a page table), then set the R/W bit in the active PDE as in the guest PDE.
   g. If D = 0 in the guest PDE, PS = 1 (this is a 4-MByte page), and the attempted access is a write; then set R/W in the active PDE as in the guest PDE and set D = 1 in the guest PDE.
   h. If D = 0 in the guest PDE, PS = 1, and the attempted access is not a write; then set R/W = 0 in the active PDE.
   i. After modifying the active PDE, re-execute the faulting instruction.

   The remaining steps assume that the active PDE is already marked present.
5. If the active PDE is the source of the fault, the active PDE refers to a 4-MByte page (PS = 1), the attempted access is a write; D = 0 in the guest PDE, and the active PDE has caused a fault solely because it has R/W = 0; then set R/W in the active PDE as in the guest PDE; set D = 1 in the guest PDE, and re-execute the faulting instruction.
6. If the active PDE is the source of the fault and none of the above cases apply, then raise a page fault of the guest operating system.

   The remaining steps assume that the source of the original page fault is not the active PDE.

**NOTE**

It is possible that the active PDE might be causing a fault even though the guest PDE would not. However, this can happen only if the guest operating system increased access in the guest PDE and did not take action to ensure that older translations were flushed from the TLB. Such translations might have caused a page fault if the guest software were running on bare hardware.

7. If the active PDE refers to a 4-MByte page (PS = 1) but is not the source of the fault, then the fault resulted from an inconsistency between the active page-table hierarchy and the processor's TLB. Since the transition to

the VMM caused an address-space change and flushed the processor's TLB, the VMM can simply re-execute the faulting instruction.

The remaining steps assume that PS = 0 in the active and guest PDEs.

8. Consult the active PTE, which can be located using the next 10 bits of the faulting address (bits 21–12) and the physical page-table base address in the active PDE. The active PTE is the source of the fault if it is marked not-present or if its R/W bit and U/S bits are inconsistent with the attempted guest access (the guest privilege level and the values of CR0.WP and CR4.SMEP should also be taken into account).
9. If the active PTE is not the source of the fault, then the fault has resulted from an inconsistency between the active page-table hierarchy and the processor's TLB. Since the transition to the VMM caused an address-space change and flushed the processor's TLB, the VMM simply re-executes the faulting instruction.

   The remaining steps assume that the active PTE is the source of the fault.
10. Consult the corresponding guest PTE using the same 10 bits from the faulting address and the physical address that correspond to the guest page-table base address in the guest PDE. If the guest PTE would cause a page fault (it is marked not-present), the raise a page fault to the guest operating system.

    The following steps assume that the guest PTE would not have caused a page fault.
11. If the guest PTE contains, as page base address, a physical address that is not valid for the virtual machine being supported; then raise a machine check (or some other abort) to the guest operating system.

    The following steps assume that the address in the guest PTE is valid for the virtual machine.
12. If the active PTE is marked not-present, then set the active PTE to correspond to guest PTE:
    a. Set the page base address in the active PTE to be the physical address that corresponds to the guest page base address in the guest PTE.
    b. Set the P, U/S, and PS bits in the active PTE to be identical to those in the guest PTE.
    c. Set the PWT, PCD, and G bits according to the policy of the VMM.
    d. Set A = 1 in the guest PTE.
    e. If D = 1 in the guest PTE, then set the R/W bit in the active PTE as in the guest PTE.
    f. If D = 0 in the guest PTE and the attempted access is a write, then set R/W in the active PTE as in the guest PTE and set D = 1 in the guest PTE.
    g. If D = 0 in the guest PTE and the attempted access is not a write, then set R/W = 0 in the active PTE.
    h. After modifying the active PTE, re-execute the faulting instruction.

    The remaining steps assume that the active PTE is already marked present.
13. If the attempted access is a write, D = 0 (not dirty) in the guest PTE and the active PTE has caused a fault solely because it has R/W = 0 (read-only); then set R/W in the active PTE as in the guest PTE, set D = 1 in the guest PTE and re-execute the faulting instruction.
14. If none of the above cases apply, then raise a page fault of the guest operating system.

#### 32.3.5.3 Response to Uses of INVLPG

Operating-systems can use INVLPG to flush entries from the TLB. This instruction takes a linear address as an operand and software expects any cached translations for the address to be flushed. A VMM should set the processor-based VM-execution control "INVLPG exiting" to 1 so that any attempts by a privileged guest to execute INVLPG will trap to the VMM. The VMM can then modify the active page-table hierarchy to emulate the desired effect of the INVLPG.

The following steps are performed. Note that these steps are performed only if the guest invocation of INVLPG would not fault and only if the guest software is running at privilege level 0:

1. Locate the relevant active PDE using the upper 10 bits of the operand address and the current value of CR3. If the PDE refers to a 4-MByte page (PS = 1), then set P = 0 in the PDE.
2. If the PDE is marked present and refers to a page table (PS = 0), locate the relevant active PTE using the next 10 bits of the operand address (bits 21–12) and the page-table base address in the PDE. Set P = 0 in the PTE.

Examine all PTEs in the page table; if they are now all marked not-present, de-allocate the page table and set P = 0 in the PDE (this step may be optional).

#### 32.3.5.4 Response to CR3 Writes

A guest operating system may attempt to write to CR3. Any write to CR3 implies a TLB flush and a possible page table change. The following steps are performed:

1. The VMM notes the new CR3 value (used later to walk guest page tables) and emulates the write.
2. The VMM allocates a new PD page, with all invalid entries.
3. The VMM sets actual processor CR3 register to point to the new PD page.

The VMM may, at this point, speculatively fill in VTLB mappings for performance reasons.

## 32.4 MICROCODE UPDATE FACILITY

The microcode code update facility may be invoked at various points during the operation of a platform. Typically, the BIOS invokes the facility on all processors during the BIOS boot process. This is sufficient to boot the BIOS and operating system. As a microcode update more current than the system BIOS may be available, system software should provide another mechanism for invoking the microcode update facility. The implications of the microcode update mechanism on the design of the VMM are described in this section.

**NOTE**

Microcode updates must not be performed during VMX non-root operation. Updates performed in VMX non-root operation may result in unpredictable system behavior.

### 32.4.1 Early Load of Microcode Updates

The microcode update facility may be invoked early in the VMM or guest OS boot process. Loading the microcode update early provides the opportunity to correct errata affecting the boot process but the technique generally requires a reboot of the software.

A microcode update may be loaded from the OS or VMM image loader. Typically, such image loaders do not run on every logical processor, so this method effects only one logical processor. Later in the VMM or OS boot process, after bringing all application processors on-line, the VMM or OS needs to invoke the microcode update facility for all application processors.

Depending on the order of the VMM and the guest OS boot, the microcode update facility may be invoked by the VMM or the guest OS. For example, if the guest OS boots first and then loads the VMM, the guest OS may invoke the microcode update facility on all the logical processors. If a VMM boots before its guests, then the VMM may invoke the microcode update facility during its boot process. In both cases, the VMM or OS should invoke the microcode update facilities soon after performing the multiprocessor startup.

In the early load scenario, microcode updates may be contained in the VMM or OS image or, the VMM or OS may manage a separate database or file of microcode updates. Maintaining a separate microcode update image database has the advantage of reducing the number of required VMM or OS releases as a result of microcode update releases.

### 32.4.2 Late Load of Microcode Updates

A microcode update may be loaded during normal system operation. This allows system software to activate the microcode update at anytime without requiring a system reboot. This scenario does not allow the microcode update to correct errata which affect the processor's boot process but does allow high-availability systems to activate microcode updates without interrupting the availability of the system. In this late load scenario, either the VMM or a designated guest may load the microcode update. If the guest is loading the microcode update, the VMM must

make sure that the entire guest memory buffer (which contains the microcode update image) will not cause a page fault when accessed.

If the VMM loads the microcode update, then the VMM must have access to the current set of microcode updates. These updates could be part of the VMM image or could be contained in a separate microcode update image database (for example: a database file on disk or in memory). Again, maintaining a separate microcode update image database has the advantage of reducing the number of required VMM or OS releases as a result of microcode update releases.

The VMM may wish to prevent a guest from loading a microcode update or may wish to support the microcode update requested by a guest using emulation (without actually loading the microcode update). To prevent microcode update loading, the VMM may return a microcode update signature value greater than the value of IA32_BIOS_SIGN_ID MSR. A well behaved guest will not attempt to load an older microcode update. The VMM may also drop the guest attempts to write to IA32_BIOS_UPDT_TRIG MSR, preventing the guest from loading any microcode updates. Later, when the guest queries IA32_BIOS_SIGN_ID MSR, the VMM could emulate the microcode update signature that the guest expects.

In general, loading a microcode update later will limit guest software’s visibility of features that may be enhanced by a microcode update.

# CHAPTER 33
# HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

## 33.1 OVERVIEW

This chapter describes what a VMM must consider when handling exceptions, interrupts, error conditions, and transitions between activity states.

## 33.2 INTERRUPT HANDLING IN VMX OPERATION

The following bullets summarize VMX support for handling interrupts:

- **Control of processor exceptions**. The VMM can get control on specific guest exceptions through the exception-bitmap in the guest controlling VMCS. The exception bitmap is a 32-bit field that allows the VMM to specify processor behavior on specific exceptions (including traps, faults, and aborts). Setting a specific bit in the exception bitmap implies VM exits will be generated when the corresponding exception occurs. Any exceptions that are programmed not to cause VM exits are delivered directly to the guest through the guest IDT. The exception bitmap also controls execution of relevant instructions such as BOUND, INTO and INT3. VM exits on page-faults are treated in such a way the page-fault error code is qualified through the page-fault-error-code mask and match fields in the VMCS.
- **Control over triple faults**. If a fault occurs while attempting to call a double-fault handler in the guest and that fault is not configured to cause a VM exit in the exception bitmap, the resulting triple fault causes a VM exit.
- **Control of external interrupts**. VMX allows both host and guest control of external interrupts through the "external-interrupt exiting" VM execution control. If the control is 0, external-interrupts do not cause VM exits and the interrupt delivery is masked by the guest programmed RFLAGS.IF value.[1] If the control is 1, external-interrupts causes VM exits and are not masked by RFLAGS.IF. The VMM can identify VM exits due to external interrupts by checking the exit reason for an "external interrupt" (value = 1).
- **Control of other events**. There is a pin-based VM-execution control that controls system behavior (exit or no-exit) for NMI events. Most VMM usages will need handling of NMI external events in the VMM and hence will specify host control of these events.

  Some processors also support a pin-based VM-execution control called "virtual NMIs." When this control is set, NMIs cause VM exits, but the processor tracks guest readiness for virtual NMIs. This control interacts with the "NMI-window exiting" VM-execution control (see below).

  INIT and SIPI events always cause VM exits.
- **Acknowledge interrupt on exit**. The "acknowledge interrupt on exit" VM-exit control in the controlling VMCS controls processor behavior for external interrupt acknowledgement. If the control is 1, the processor acknowledges the interrupt controller to acquire the interrupt vector upon VM exit, and stores the vector in the VM-exit interruption-information field. If the control is 0, the external interrupt is not acknowledged during VM exit. Since RFLAGS.IF is automatically cleared on VM exits due to external interrupts, VMM re-enabling of interrupts (setting RFLAGS.IF = 1) initiates the external interrupt acknowledgement and vectoring of the external interrupt through the monitor/host IDT.
- **Event-masking Support**. VMX captures the masking conditions of specific events while in VMX non-root operation through the interruptibility-state field in the guest-state area of the VMCS.

  This feature allows proper virtualization of various interrupt blocking states, such as: (a) blocking of external interrupts for the instruction following STI; (b) blocking of interrupts for the instruction following a MOV-SS or POP-SS instruction; (c) SMI blocking of subsequent SMIs until the next execution of RSM; and (d) NMI/SMI blocking of NMIs until the next execution of IRET or RSM.

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.).

INIT and SIPI events are treated specially. INIT assertions are always blocked in VMX root operation and while in SMM, and unblocked otherwise. SIPI events are always blocked in VMX root operation.

The interruptibility state is loaded from the VMCS guest-state area on every VM entry and saved into the VMCS on every VM exit.

- **Event injection**. VMX operation allows injecting interruptions to a guest virtual machine through the use of VM-entry interrupt-information field in VMCS. Injectable interruptions include external interrupts, NMI, processor exceptions, software generated interrupts, and software traps. If the interrupt-information field indicates a valid interrupt, exception or trap event upon the next VM entry; the processor will use the information in the field to vector a virtual interruption through the guest IDT after all guest state and MSRs are loaded. Delivery through the guest IDT emulates vectoring in non-VMX operation by doing the normal privilege checks and pushing appropriate entries to the guest stack (entries may include RFLAGS, EIP and exception error code). A VMM with host control of NMI and external interrupts can use the event-injection facility to forward virtual interruptions to various guest virtual machines.
- **Interrupt-window exiting**. When set to 1, the "interrupt-window exiting" VM-execution control (Section 24.6.2) causes VM exits when guest RFLAGS.IF is 1 and no other conditions block external interrupts. A VM exit occurs at the beginning of any instruction at which RFLAGS.IF = 1 and on which the interruptibility state of the guest would allow delivery of an interrupt. For example: when the guest executes an STI instruction, RFLAGS = 1, and if at the completion of next instruction the interruptibility state masking due to STI is removed; a VM exit occurs if the "interrupt-window exiting" VM-execution control is 1. This feature allows a VMM to queue a virtual interrupt to the guest when the guest is not in an interruptible state. The VMM can set the "interrupt-window exiting" VM-execution control for the guest and depend on a VM exit to know when the guest becomes interruptible (and, therefore, when it can inject a virtual interrupt). The VMM can detect such VM exits by checking for the basic exit reason "interrupt-window" (value = 7). If this feature is not used, the VMM will need to poll and check the interruptibility state of the guest to deliver virtual interrupts.
- **NMI-window exiting**. If the "virtual NMIs" VM-execution is set, the processor tracks virtual-NMI blocking. The "NMI-window exiting" VM-execution control (Section 24.6.2) causes VM exits when there is no virtual-NMI blocking. For example, after execution of the IRET instruction, a VM exit occurs if the "NMI-window exiting" VM-execution control is 1. This feature allows a VMM to queue a virtual NMI to a guest when the guest is not ready to receive NMIs. The VMM can set the "NMI-window exiting" VM-execution control for the guest and depend on a VM exit to know when the guest becomes ready for NMIs (and, therefore, when it can inject a virtual NMI). The VMM can detect such VM exits by checking for the basic exit reason "NMI window" (value = 8). If this feature is not used, the VMM will need to poll and check the interruptibility state of the guest to deliver virtual NMIs.
- **VM-exit information**. The VM-exit information fields provide details on VM exits due to exceptions and interrupts. This information is provided through the exit-qualification, VM-exit-interruption-information, instruction-length and interruption-error-code fields. Also, for VM exits that occur in the course of vectoring through the guest IDT, information about the event that was being vectored through the guest IDT is provided in the IDT-vectoring-information and IDT-vectoring-error-code fields. These information fields allow the VMM to identify the exception cause and to handle it properly.

## 33.3 EXTERNAL INTERRUPT VIRTUALIZATION

VMX operation allows both host and guest control of external interrupts. While guest control of external interrupts might be suitable for partitioned usages (different CPU cores/threads and I/O devices partitioned to independent virtual machines), most VMMs built upon VMX are expected to utilize host control of external interrupts. The rest of this section describes a general host-controlled interrupt virtualization architecture for standard PC platforms through the use of VMX supported features.

With host control of external interrupts, the VMM (or the host OS in a hosted VMM model) manages the physical interrupt controllers in the platform and the interrupts generated through them. The VMM exposes software-emulated virtual interrupt controller devices (such as PIC and APIC) to each guest virtual machine instance.

### 33.3.1 Virtualization of Interrupt Vector Space

The Intel 64 and IA-32 architectures use 8-bit vectors of which 224 (20H – FFH) are available for external interrupts. Vectors are used to select the appropriate entry in the interrupt descriptor table (IDT). VMX operation allows each guest to control its own IDT. Host vectors refer to vectors delivered by the platform to the processor during the interrupt acknowledgement cycle. Guest vectors refer to vectors programmed by a guest to select an entry in its guest IDT. Depending on the I/O resource management models supported by the VMM design, the guest vector space may or may not overlap with the underlying host vector space.

- Interrupts from virtual devices: Guest vector numbers for virtual interrupts delivered to guests on behalf of emulated virtual devices have no direct relation to the host vector numbers of interrupts from physical devices on which they are emulated. A guest-vector assigned for a virtual device by the guest operating environment is saved by the VMM and utilized when injecting virtual interrupts on behalf of the virtual device.
- Interrupts from assigned physical devices: Hardware support for I/O device assignment allows physical I/O devices in the host platform to be assigned (direct-mapped) to VMs. Guest vectors for interrupts from direct-mapped physical devices take up equivalent space from the host vector space, and require the VMM to perform host-vector to guest-vector mapping for interrupts.

Figure 33-1 illustrates the functional relationship between host external interrupts and guest virtual external interrupts. Device A is owned by the host and generates external interrupts with host vector X. The host IDT is set up such that the interrupt service routine (ISR) for device driver A is hooked to host vector X as normal. VMM emulates (over device A) virtual device C in software which generates virtual interrupts to the VM with guest expected vector P. Device B is assigned to a VM and generates external interrupts with host vector Y. The host IDT is programmed to hook the VMM interrupt service routine (ISR) for assigned devices for vector Y, and the VMM handler injects virtual interrupt with guest vector Q to the VM. The guest operating system programs the guest to hook appropriate guest driver’s ISR to vectors P and Q.

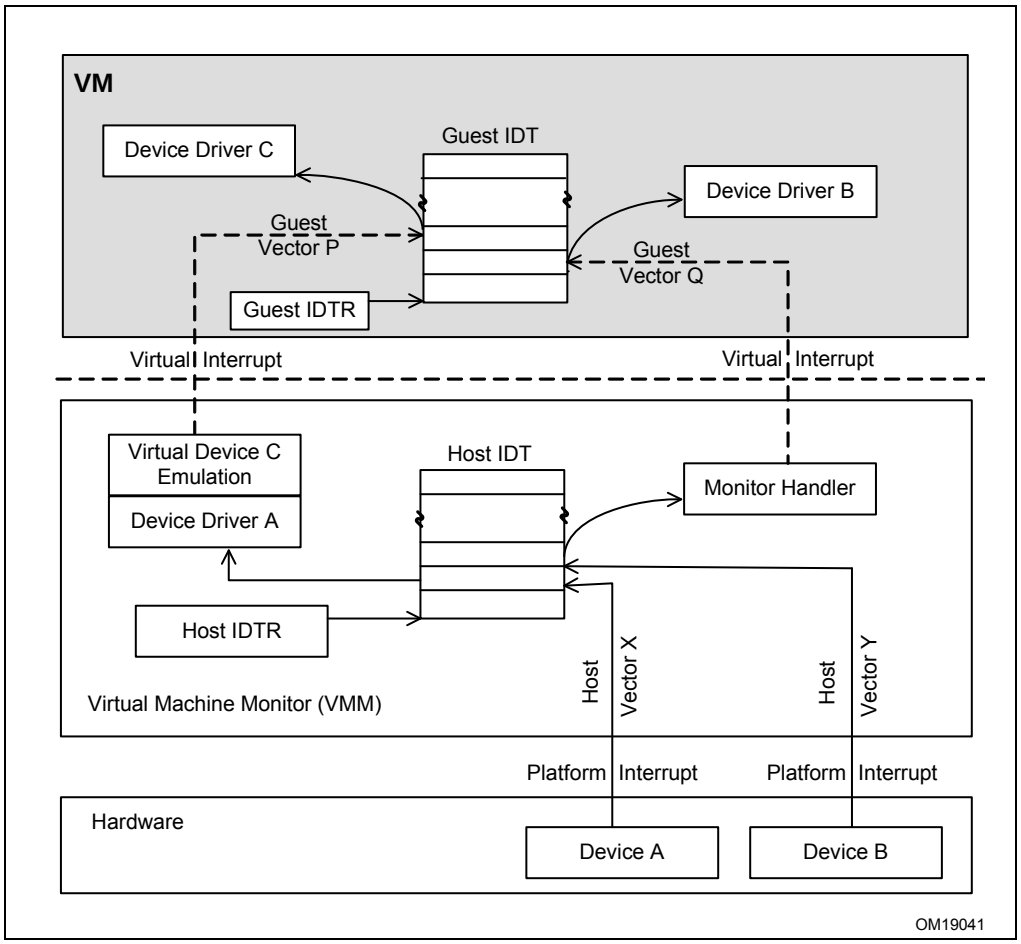

**Figure 33-1. Host External Interrupts and Guest Virtual Interrupts**

## 33.3.2 Control of Platform Interrupts

To meet the interrupt virtualization requirements, the VMM needs to take ownership of the physical interrupts and the various interrupt controllers in the platform. VMM control of physical interrupts may be enabled through the host-control settings of the "external-interrupt exiting" VM-execution control. To take ownership of the platform interrupt controllers, the VMM needs to expose the virtual interrupt controller devices to the virtual machines and restrict guest access to the platform interrupt controllers.

Intel 64 and IA-32 platforms can support three types of external interrupt control mechanisms: Programmable Interrupt Controllers (PIC), Advanced Programmable Interrupt Controllers (APIC), and Message Signaled Interrupts (MSI). The following sections provide information on the virtualization of each of these mechanisms.

### 33.3.2.1 PIC Virtualization

Typical PIC-enabled platform implementations support dual 8259 interrupt controllers cascaded as master and slave controllers. They supporting up to 15 possible interrupt inputs. The 8259 controllers are programmed through initialization command words (ICWx) and operation command words (OCWx) accessed through specific I/O ports. The various interrupt line states are captured in the PIC through interrupt requests, interrupt service routines and interrupt mask registers.

Guest access to the PIC I/O ports can be restricted by activating I/O bitmaps in the guest controlling-VMCS (activate-I/O-bitmap bit in VM-execution control field set to 1) and pointing the I/O-bitmap physical addresses to valid

bitmap regions. Bits corresponding to the PIC I/O ports can be cleared to cause a VM exit on guest access to these ports.

If the VMM is not supporting direct access to any I/O ports from a guest, it can set the unconditional-I/O-exiting in the VM-execution control field instead of activating I/O bitmaps. The exit-reason field in VM-exit information allows identification of VM exits due to I/O access and can provide an exit-qualification to identify details about the guest I/O operation that caused the VM exit.

The VMM PIC virtualization needs to emulate the platform PIC functionality including interrupt priority, mask, request and service states, and specific guest programmed modes of PIC operation.

#### 33.3.2.2 xAPIC Virtualization

Most modern Intel 64 and IA-32 platforms include support for an APIC. While the standard PIC is intended for use on uniprocessor systems, APIC can be used in either uniprocessor or multi-processor systems.

APIC based interrupt control consists of two physical components: the interrupt acceptance unit (Local APIC) which is integrated with the processor, and the interrupt delivery unit (I/O APIC) which is part of the I/O subsystem. APIC virtualization involves protecting the platform's local and I/O APICs and emulating them for the guest.

#### 33.3.2.3 Local APIC Virtualization

The local APIC is responsible for the local interrupt sources, interrupt acceptance, dispensing interrupts to the logical processor, and generating inter-processor interrupts. Software interacts with the local APIC by reading and writing its memory-mapped registers residing within a 4-KByte uncached memory region with base address stored in the IA32_APIC_BASE MSR. Since the local APIC registers are memory-mapped, the VMM can utilize memory virtualization techniques (such as page-table virtualization) to trap guest accesses to the page frame hosting the virtual local APIC registers.

Local APIC virtualization in the VMM needs to emulate the various local APIC operations and registers, such as: APIC identification/format registers, the local vector table (LVT), the interrupt command register (ICR), interrupt capture registers (TMR, IRR and ISR), task and processor priority registers (TPR, PPR), the EOI register and the APIC-timer register. Since local APICs are designed to operate with non-specific EOI, local APIC emulation also needs to emulate broadcast of EOI to the guest's virtual I/O APICs for level triggered virtual interrupts.

A local APIC allows interrupt masking at two levels: (1) mask bit in the local vector table entry for local interrupts and (2) raising processor priority through the TPR registers for masking lower priority external interrupts. The VMM needs to comprehend these virtual local APIC mask settings as programmed by the guest in addition to the guest virtual processor interruptibility state (when injecting APIC routed external virtual interrupts to a guest VM).

VMX provides several features which help the VMM to virtualize the local APIC. These features allow many of guest TPR accesses (using CR8 only) to occur without VM exits to the VMM:

- The VMCS contains a "virtual-APIC address" field. This 64-bit field is the physical address of the 4-KByte virtual APIC page (4-KByte aligned). The virtual-APIC page contains a TPR shadow, which is accessed by the MOV CR8 instruction. The TPR shadow comprises bits 7:4 in byte 80H of the virtual-APIC page.
- The TPR threshold: bits 3:0 of this 32-bit field determine the threshold below which the TPR shadow cannot fall. A VM exit will occur after an execution of MOV CR8 that reduces the TPR shadow below this value.
- The processor-based VM-execution controls field contains a "use TPR shadow" bit and a "CR8-store exiting" bit. If the "use TPR shadow" VM-execution control is 1 and the "CR8-store exiting" VM-execution control is 0, then a MOV from CR8 reads from the TPR shadow. If the "CR8-store exiting" VM-execution control is 1, then MOV from CR8 causes a VM exit; the "use TPR shadow" VM-execution control is ignored in this case.
- The processor-based VM-execution controls field contains a "CR8-load exiting" bit. If the "use TPR shadow" VM-execution control is set and the "CR8-load exiting" VM-execution control is clear, then MOV to CR8 writes to the "TPR shadow". A VM exit will occur after this write if the value written is below the TPR threshold. If the "CR8-load exiting" VM-execution control is set, then MOV to CR8 causes a VM exit; the "use TPR shadow" VM-execution control is ignored in this case.

#### 33.3.2.4 I/O APIC Virtualization

The I/O APIC registers are typically mapped to a 1 MByte region where each I/O APIC is allocated a 4K address window within this range. The VMM may utilize physical memory virtualization to trap guest accesses to the virtual I/O APIC memory-mapped registers. The I/O APIC virtualization needs to emulate the various I/O APIC operations and registers such as identification/version registers, indirect-I/O-access registers, EOI register, and the I/O redirection table. I/O APIC virtualization also need to emulate various redirection table entry settings such as delivery mode, destination mode, delivery status, polarity, masking, and trigger mode programmed by the guest and track remote-IRR state on guest EOI writes to various virtual local APICs.

#### 33.3.2.5 Virtualization of Message Signaled Interrupts

The *PCI Local Bus Specification* (Rev. 2.2) introduces the concept of message signaled interrupts (MSI). MSI enable PCI devices to request service by writing a system-specified message to a system specified address. The transaction address specifies the message destination while the transaction data specifies the interrupt vector, trigger mode and delivery mode. System software is expected to configure the message data and address during MSI device configuration, allocating one or more no-shared messages to MSI capable devices. Chapter 10, "Advanced Programmable Interrupt Controller (APIC)," specifies the MSI message address and data register formats to be followed on Intel 64 and IA-32 platforms. While MSI is optional for conventional PCI devices, it is the preferred interrupt mechanism for PCI-Express devices.

Since the MSI address and data are configured through PCI configuration space, to control these physical interrupts the VMM needs to assume ownership of PCI configuration space. This allows the VMM to capture the guest configuration of message address and data for MSI-capable virtual and assigned guest devices. PCI configuration transactions on PC-compatible systems are generated by software through two different methods:

1. The standard CONFIG_ADDRESS/CONFIG_DATA register mechanism (CFCH/CF8H ports) as defined in the *PCI Local Bus Specification.*
2. The enhanced flat memory-mapped (MEMCFG) configuration mechanism as defined in the *PCI-Express Base Specification* (Rev. 1.0a.).

The CFCH/CF8H configuration access from guests can be trapped by the VMM through use of I/O-bitmap VM-execution controls. The memory-mapped PCI-Express MEMCFG guest configuration accesses can be trapped by VMM through physical memory virtualization.

### 33.3.3 Examples of Handling of External Interrupts

The following sections illustrate interrupt processing in a VMM (when used to support the external interrupt virtualization requirements).

#### 33.3.3.1 Guest Setup

The VMM sets up the guest to cause a VM exit to the VMM on external interrupts. This is done by setting the "external-interrupt exiting" VM-execution control in the guest controlling-VMCS.

#### 33.3.3.2 Processor Treatment of External Interrupt

Interrupts are automatically masked by hardware in the processor on VM exit by clearing RFLAGS.IF. The exit-reason field in VMCS is set to 1 to indicate an external interrupt as the exit reason.

If the VMM is utilizing the acknowledge-on-exit feature (by setting the "acknowledge interrupt on exit" VM-exit control), the processor acknowledges the interrupt, retrieves the host vector, and saves the interrupt in the VM-exit-interruption-information field (in the VM-exit information region of the VMCS) before transitioning control to the VMM.

### 33.3.3.3 Processing of External Interrupts by VMM

Upon VM exit, the VMM can determine the exit cause of an external interrupt by checking the exit-reason field (value = 1) in VMCS. If the acknowledge-interrupt-on-exit control (see Section 24.7.1) is enabled, the VMM can use the saved host vector (in the exit-interruption-information field) to switch to the appropriate interrupt handler. If the "acknowledge interrupt on exit" VM-exit control is 0, the VMM may re-enable interrupts (by setting RFLAGS.IF) to allow vectoring of external interrupts through the monitor/host IDT.

The following steps may need to be performed by the VMM to process an external interrupt:

- **Host Owned I/O Devices:** For host-owned I/O devices, the interrupting device is owned by the VMM (or hosting OS in a hosted VMM). In this model, the interrupt service routine in the VMM/host driver is invoked and, upon ISR completion, the appropriate write sequences (TPR updates, EOI etc.) to respective interrupt controllers are performed as normal. If the work completion indicated by the driver implies virtual device activity, the VMM runs the virtual device emulation. Depending on the device class, physical device activity could imply activity by multiple virtual devices mapped over the device. For each affected virtual device, the VMM injects a virtual external interrupt event to respective guest virtual machines. The guest driver interacts with the emulated virtual device to process the virtual interrupt. The interrupt controller emulation in the VMM supports various guest accesses to the VMM's virtual interrupt controller.
- **Guest Assigned I/O Devices:** For assigned I/O devices, either the VMM uses a software proxy or it can directly map the physical device to the assigned VM. In both cases, servicing of the interrupt condition on the physical device is initiated by the driver running inside the guest VM. With host control of external interrupts, interrupts from assigned physical devices cause VM exits to the VMM and vectoring through the host IDT to the registered VMM interrupt handler. To unblock delivery of other low priority platform interrupts, the VMM interrupt handler must mask the interrupt source (for level triggered interrupts) and issue the appropriate EOI write sequences.

Once the physical interrupt source is masked and the platform EOI generated, the VMM can map the host vector to its corresponding guest vector to inject the virtual interrupt into the assigned VM. The guest software does EOI write sequences to its virtual interrupt controller after completing interrupt processing. For level triggered interrupts, these EOI writes to the virtual interrupt controller may be trapped by the VMM which may in turn unmask the previously masked interrupt source.

### 33.3.3.4 Generation of Virtual Interrupt Events by VMM

The following provides some of the general steps that need to be taken by VMM designs when generating virtual interrupts:

1. Check virtual processor interruptibility state. The virtual processor interruptibility state is reflected in the guest RFLAGS.IF flag and the processor interruptibility-state saved in the guest state area of the controlling-VMCS. If RFLAGS.IF is set and the interruptibility state indicates readiness to take external interrupts (STI-masking and MOV-SS/POP-SS-masking bits are clear), the guest virtual processor is ready to take external interrupts. If the VMM design supports non-active guest sleep states, the VMM needs to make sure the current guest sleep state allows injection of external interrupt events.
2. If the guest virtual processor state is currently not interruptible, a VMM may utilize the "interrupt-window exiting" VM-execution to notify the VM (through a VM exit) when the virtual processor state changes to interruptible state.
3. Check the virtual interrupt controller state. If the guest VM exposes a virtual local APIC, the current value of its processor priority register specifies if guest software allows dispensing an external virtual interrupt with a specific priority to the virtual processor. If the virtual interrupt is routed through the local vector table (LVT) entry of the local APIC, the mask bits in the corresponding LVT entry specifies if the interrupt is currently masked. Similarly, the virtual interrupt controller's current mask (IO-APIC or PIC) and priority settings reflect guest state to accept specific external interrupts. The VMM needs to check both the virtual processor and interrupt controller states to verify its guest interruptibility state. If the guest is currently interruptible, the VMM can inject the virtual interrupt. If the current guest state does not allow injecting a virtual interrupt, the interrupt needs to be queued by the VMM until it can be delivered.
4. Prioritize the use of VM-entry event injection. A VMM may use VM-entry event injection to deliver various virtual events (such as external interrupts, exceptions, traps, and so forth). VMM designs may prioritize use of virtual-interrupt injection between these event types. Since each VM entry allows injection of one event,

depending on the VMM event priority policies, the VMM may need to queue the external virtual interrupt if a higher priority event is to be delivered on the next VM entry. Since the VMM has masked this particular interrupt source (if it was level triggered) and done EOI to the platform interrupt controller, other platform interrupts can be serviced while this virtual interrupt event is queued for later delivery to the VM.

5. Update the virtual interrupt controller state. When the above checks have passed, before generating the virtual interrupt to the guest, the VMM updates the virtual interrupt controller state (Local-APIC, IO-APIC and/or PIC) to reflect assertion of the virtual interrupt. This involves updating the various interrupt capture registers, and priority registers as done by the respective hardware interrupt controllers. Updating the virtual interrupt controller state is required for proper interrupt event processing by guest software.
6. Inject the virtual interrupt on VM entry. To inject an external virtual interrupt to a guest VM, the VMM sets up the VM-entry interruption-information field in the guest controlling-VMCS before entry to guest using VMRESUME. Upon VM entry, the processor will use this vector to access the gate in guest's IDT and the value of RFLAGS and EIP in guest-state area of controlling-VMCS is pushed on the guest stack. If the guest RFLAGS.IF is clear, the STI-masking bit is set, or the MOV- SS/POP-SS-masking bit is set, the VM entry will fail and the processor will load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 26.7).

## 33.4 ERROR HANDLING BY VMM

Error conditions may occur during VM entries and VM exits and a few other situations. This section describes how VMM should handle these error conditions, including triple faults and machine-check exceptions.

### 33.4.1 VM-Exit Failures

All VM exits load processor state from the host-state area of the VMCS that was the controlling VMCS before the VM exit. This state is checked for consistency while being loaded. Because the host-state is checked on VM entry, these checks will generally succeed. Failure is possible only if host software is incorrect or if VMCS data in the VMCS region in memory has been written by guest software (or by I/O DMA) since the last VM entry. VM exits may fail for the following reasons:

- There was a failure on storing guest MSRs.
- There was failure in loading a PDPTR.
- The controlling VMCS has been corrupted (through writes to the corresponding VMCS region) in such a way that the implementation cannot complete the VM exit.
- There was a failure on loading host MSRs.
- A machine-check event occurred.

If one of these problems occurs on a VM exit, a VMX abort results.

### 33.4.2 Machine-Check Considerations

The following sequence determine how machine-check events are handled during VMXON, VMXOFF, VM entries, and VM exits:

- VMXOFF and VMXON:

  If a machine-check event occurs during VMXOFF or VMXON and CR4.MCE = 1, a machine-check exception (#MC) is generated. If CR4.MCE = 0, the processor goes to shutdown state.

- VM entry:

  If a machine-check event occurs during VM entry, one of the following three treatments must occur:

  a. Normal delivery before VM entry. If CR4.MCE = 1 before VM entry, delivery of a machine-check exception (#MC) through the host IDT occurs. If CR4.MCE = 0, the processor goes to shutdown state.

b. Normal delivery after VM entry. If CR4.MCE = 1 after VM entry, delivery of a machine-check exception (#MC) through the guest IDT occurs (alternatively, this exception may cause a VM exit). If CR4.MCE = 0, the processor goes to shutdown state.

c. Load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 26.7). The basic exit reason will be "VM-entry failure due to machine-check event."

If the machine-check event occurs after any guest state has been loaded, option a above will not be used; it may be used if the machine-check event occurs while checking host state and VMX controls (or while reporting a failure due to such checks). An implementation may use option b only if all guest state has been loaded properly.

- VM exit:

  If a machine-check event occurs during VM exit, one of the following three treatments must occur:

  a. Normal delivery before VM exit. If CR4.MCE = 1 before the VM exit, delivery of a machine-check exception (#MC) through the guest IDT (alternatively, this may cause a VM exit). If CR4.MCE = 0, the processor goes to shutdown state.

  b. Normal delivery after VM exit. If CR4.MCE = 1 after the VM exit, delivery of a machine-check exception (#MC) through the host IDT. If CR4.MCE = 0, the processor goes to shutdown state.

  c. Fail the VM exit. If the VM exit is to VMX root operation, a VMX abort will result; it will block events as done normally in VMX abort. The VMX abort indicator will show that a machine-check event induced the abort operation.

  If a machine-check event is induced by an action in VMX non-root operation before any determination is made that the inducing action may cause a VM exit, that machine-check event should be considered as happening during guest execution in VMX non-root operation. This is the case even if the part of the action that caused the machine-check event was VMX-specific (for example, the processor's consulting an I/O bitmap). If a machine-check exception occurs and if bit 12H of the exception bitmap is cleared to 0, the exception is delivered to the guest through gate 12H of its IDT; if the bit is set to 1, the machine-check exception causes a VM exit.

**NOTE**

The state saved in the guest-state area on VM exits due to machine-check exceptions should be considered suspect. A VMM should consult the RIPV and EIPV bits in the IA32_MCG_STATUS MSR before resuming a guest that caused a VM exit due to a machine-check exception.

### 33.4.3 MCA Error Handling Guidelines for VMM

Section 33.4.2 covers general requirements for VMMs to handle machine-check exceptions, when normal operation of the guest machine and/or the VMM is no longer possible. enhancements of machine-check architecture in newer processors may support software recovery of uncorrected MC errors (UCR) signaled through either machine-check exceptions or corrected machine-check interrupt (CMCI). Section 15.5 and Section 15.6 describes details of these more recent enhancements of machine-check architecture.

In general, Virtual Machine Monitor (VMM) error handling should follow the recommendations for OS error handling described in Section 15.3, Section 15.6, Section 15.9, and Section 15.10. This section describes additional guidelines for hosted and native hypervisor-based VMM implementations to support corrected MC errors and recoverable uncorrected MC errors.

Because a hosted VMM provides virtualization services in the context of an existing standard host OS, the host OS controls platform hardware through the host OS services such as the standard OS device drivers. In hosted VMMs. MCA errors will be handled by the host OS error handling software.

In native VMMs, the hypervisor runs on the hardware directly, and may provide only a limited set of platform services for guest VMs. Most platform services may instead be provided by a "control OS". In hypervisor-based VMMs, MCA errors will either be delivered directly to the VMM MCA handler (when the error is signaled while in the VMM context) or cause by a VM exit from a guest VM or be delivered to the MCA intercept handler. There are two general approaches the hypervisor can use to handle the MCA error: either within the hypervisor itself or by forwarding the error to the control OS.

#### 33.4.3.1 VMM Error Handling Strategies

Broadly speaking, there are two strategies that VMMs may take for error handling:

- Basic error handling: in this approach the guest VM is treated as any other thread of execution. If the error recovery action does not support restarting the thread after handling the error, the guest VM should be terminated.
- MCA virtualization: in this approach, the VMM virtualizes the MCA events and hardware. This enables the VMM to intercept MCA events and inject an MCA into the guest VM. The guest VM then has the opportunity to attempt error recovery actions, rather than being terminated by the VMM.

Details of these approaches and implementation considerations for hosted and native VMMs are discussed below.

#### 33.4.3.2 Basic VMM MCA error recovery handling

The simplest approach is for the VMM to treat the guest VM as any other thread of execution:

- MCE's that occur outside the stream of execution of a virtual machine guest will cause an MCE abort and may be handled by the MCA error handler following the recovery actions and guidelines described in Section 15.9, and Section 15.10. This includes logging the error and taking appropriate recovery actions when necessary. The VMM must not resume the interrupted thread of execution or another VM until it has taken the appropriate recovery action or, in the case of fatal MCAs, reset the system.
- MCE's that occur while executing in the context of a virtual machine will be intercepted by the VMM. The MCA intercept handler may follow the error handling guidelines listed in Section 15.9 and Section 15.10 for SRAO and SRAR errors. For SRAR errors, terminating the thread of execution will involve terminating the affected guest VM. For fatal errors the MCA handler should log the error and reset the system -- the VMM should not resume execution of the interrupted VM.

#### 33.4.3.3 Implementation Considerations for the Basic Model

For hosted VMMs, the host OS MCA error handling code will perform error analysis and initiate the appropriate recovery actions. For the basic model this flow does not change when terminating a guest VM although the specific actions needed to terminate a guest VM may be different than terminating an application or user process.

For native, hypervisor-based VMMs, MCA errors will either be delivered directly to the VMM MCA handler (when the error is signaled while in the VMM context) or cause a VM exit from a guest VM or be delivered to the MCA intercept handler. There are two general approaches the hypervisor can use to handle the MCA error: either by forwarding the error to the control OS or within the hypervisor itself. These approaches are described in the following paragraphs.

The hypervisor may forward the error to the control OS for handling errors. This approach simplifies the hypervisor error handling since it relies on the control OS to implement the basic error handling model. The control OS error handling code will be similar to the error handling code in the hosted VMM. Errors can be forwarded to the control OS via an OS callback or by injecting an MCE event into the control OS. Injecting an MCE will cause the control OS MCA error handler to be invoked. The control OS is responsible for terminating the affected guest VM, if necessary, which may require cooperation from the hypervisor.

Alternatively, the error may be handled completely in the hypervisor. The hypervisor error handler is enhanced to implement the basic error handling model and the hypervisor error handler has the capability to fully analyze the error information and take recovery actions based on the guidelines. In this case error handling steps in the hypervisor are similar to those for the hosted VMM described above (where the hypervisor replaces the host OS actions). The hypervisor is responsible for terminating the affected guest VM, if necessary.

In all cases, if a fatal error is detected the VMM error handler should log the error and reset the system. The VMM error handler must ensure that guest VMs are not resumed after a fatal error is detected to ensure error containment is maintained.

#### 33.4.3.4 MCA Virtualization

A more sophisticated approach for handling errors is to virtualize the MCA. This involves virtualizing the MCA hardware and intercepting the MCA event in the VMM when a guest VM is interrupted by an MCA. After analyzing the

error, the VMM error handler may then decide to inject an MCE abort into the guest VM for attempted guest VM error recovery. This would enable the guest OS the opportunity to take recovery actions specific to that guest.

For MCA virtualization, the VMM must provide the guest physical address for memory errors instead of the system physical address when reporting the errors to the guest VM. To compute the guest physical address, the VMM needs to maintain a reverse mapping of system physical page addresses to guest physical page addresses.

When the MCE is injected into the guest VM, the guest OS MCA handler would be invoked. The guest OS implements the MCA handling guidelines and it could potentially terminate the interrupted thread of execution within the guest instead of terminating the VM. The guest OS may also disable use of the affected page by the guest. When disabling the page the VMM error handler may handle the case where a page is shared by the VMM and a guest or by two guests. In these cases the page use must be disabled in both contexts to ensure no subsequent consumption errors are generated.

#### 33.4.3.5 Implementation Considerations for the MCA Virtualization Model

MCA virtualization may be done in either hosted VMMs or hypervisor-based VMMs. The error handling flow is similar to the flow described in the basic handling case. The major difference is that the recovery action includes injecting the MCE abort into the guest VM to enable recovery by the guest OS when the MCA interrupts the execution of a guest VM.

## 33.5 HANDLING ACTIVITY STATES BY VMM

A VMM might place a logic processor in the wait-for-SIPI activity state if supporting certain guest operating system using the multi-processor (MP) start-up algorithm. A guest with direct access to the physical local APIC and using the MP start-up algorithm sends an INIT-SIPI-SIPI IPI sequence to start the application processor. In order to trap the SIPIs, the VMM must start the logic processor which is the target of the SIPIs in wait-for-SIPI mode.

# CHAPTER 34
# SYSTEM MANAGEMENT MODE

This chapter describes aspects of IA-64 and IA-32 architecture used in system management mode (SMM).

SMM provides an alternate operating environment that can be used to monitor and manage various system resources for more efficient energy usage, to control system hardware, and/or to run proprietary code. It was introduced into the IA-32 architecture in the Intel386 SL processor (a mobile specialized version of the Intel386 processor). It is also available in the Pentium M, Pentium 4, Intel Xeon, P6 family, and Pentium and Intel486 processors (beginning with the enhanced versions of the Intel486 SL and Intel486 processors).

## 34.1 SYSTEM MANAGEMENT MODE OVERVIEW

SMM is a special-purpose operating mode provided for handling system-wide functions like power management, system hardware control, or proprietary OEM-designed code. It is intended for use only by system firmware, not by applications software or general-purpose systems software. The main benefit of SMM is that it offers a distinct and easily isolated processor environment that operates transparently to the operating system or executive and software applications.

When SMM is invoked through a system management interrupt (SMI), the processor saves the current state of the processor (the processor's context), then switches to a separate operating environment defined by a new address space. The system management software executive (SMI handler) starts execution in that environment, and the critical code and data of the SMI handler reside in a physical memory region (SMRAM) within that address space. While in SMM, the processor executes SMI handler code to perform operations such as powering down unused disk drives or monitors, executing proprietary code, or placing the whole system in a suspended state. When the SMI handler has completed its operations, it executes a resume (RSM) instruction. This instruction causes the processor to reload the saved context of the processor, switch back to protected or real mode, and resume executing the interrupted application or operating-system program or task.

The following SMM mechanisms make it transparent to applications programs and operating systems:

- The only way to enter SMM is by means of an SMI.
- The processor executes SMM code in a separate address space that can be made inaccessible from the other operating modes.
- Upon entering SMM, the processor saves the context of the interrupted program or task.
- All interrupts normally handled by the operating system are disabled upon entry into SMM.
- The RSM instruction can be executed only in SMM.

Section 34.3 describes transitions into and out of SMM. The execution environment after entering SMM is in real-address mode with paging disabled (CR0.PE = CR0.PG = 0). In this initial execution environment, the SMI handler can address up to 4 GBytes of memory and can execute all I/O and system instructions. Section 34.5 describes in detail the initial SMM execution environment for an SMI handler and operation within that environment. The SMI handler may subsequently switch to other operating modes while remaining in SMM.

**NOTES**

Software developers should be aware that, even if a logical processor was using the physical-address extension (PAE) mechanism (introduced in the P6 family processors) or was in IA-32e mode before an SMI, this will not be the case after the SMI is delivered. This is because delivery of an SMI disables paging (see Table 34-4). (This does not apply if the dual-monitor treatment of SMIs and SMM is active; see Section 34.15.)

### 34.1.1 System Management Mode and VMX Operation

Traditionally, SMM services system management interrupts and then resumes program execution (back to the software stack consisting of executive and application software; see Section 34.2 through Section 34.13).

A virtual machine monitor (VMM) using VMX can act as a host to multiple virtual machines and each virtual machine can support its own software stack of executive and application software. On processors that support VMX, virtual-machine extensions may use system-management interrupts (SMIs) and system-management mode (SMM) in one of two ways:

- **Default treatment.** System firmware handles SMIs. The processor saves architectural states and critical states relevant to VMX operation upon entering SMM. When the firmware completes servicing SMIs, it uses RSM to resume VMX operation.
- **Dual-monitor treatment.** Two VM monitors collaborate to control the servicing of SMIs: one VMM operates outside of SMM to provide basic virtualization in support for guests; the other VMM operates inside SMM (while in VMX operation) to support system-management functions. The former is referred to as **executive monitor**, the latter **SMM-transfer monitor** (**STM**).[1]

The default treatment is described in Section 34.14, "Default Treatment of SMIs and SMM with VMX Operation and SMX Operation". Dual-monitor treatment of SMM is described in Section 34.15, "Dual-Monitor Treatment of SMIs and SMM".

## 34.2 SYSTEM MANAGEMENT INTERRUPT (SMI)

The only way to enter SMM is by signaling an SMI through the SMI# pin on the processor or through an SMI message received through the APIC bus. The SMI is a nonmaskable external interrupt that operates independently from the processor's interrupt- and exception-handling mechanism and the local APIC. The SMI takes precedence over an NMI and a maskable interrupt. SMM is non-reentrant; that is, the SMI is disabled while the processor is in SMM.

### NOTES

In the Pentium 4, Intel Xeon, and P6 family processors, when a processor that is designated as an application processor during an MP initialization sequence is waiting for a startup IPI (SIPI), it is in a mode where SMIs are masked. However if a SMI is received while an application processor is in the wait for SIPI mode, the SMI will be pended. The processor then responds on receipt of a SIPI by immediately servicing the pended SMI and going into SMM before handling the SIPI.

An SMI may be blocked for one instruction following execution of STI, MOV to SS, or POP into SS.

## 34.3 SWITCHING BETWEEN SMM AND THE OTHER PROCESSOR OPERATING MODES

Figure 2-3 shows how the processor moves between SMM and the other processor operating modes (protected, real-address, and virtual-8086). Signaling an SMI while the processor is in real-address, protected, or virtual-8086 modes always causes the processor to switch to SMM. Upon execution of the RSM instruction, the processor always returns to the mode it was in when the SMI occurred.

### 34.3.1 Entering SMM

The processor always handles an SMI on an architecturally defined "interruptible" point in program execution (which is commonly at an IA-32 architecture instruction boundary). When the processor receives an SMI, it waits for all instructions to retire and for all stores to complete. The processor then saves its current context in SMRAM (see Section 34.4), enters SMM, and begins to execute the SMI handler.

Upon entering SMM, the processor signals external hardware that SMI handling has begun. The signaling mechanism used is implementation dependent. For the P6 family processors, an SMI acknowledge transaction is gener-

1. The dual-monitor treatment may not be supported by all processors. Software should consult the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1) to determine whether it is supported.

ated on the system bus and the multiplexed status signal EXF4 is asserted each time a bus transaction is generated while the processor is in SMM. For the Pentium and Intel486 processors, the SMIACT# pin is asserted.

An SMI has a greater priority than debug exceptions and external interrupts. Thus, if an NMI, maskable hardware interrupt, or a debug exception occurs at an instruction boundary along with an SMI, only the SMI is handled. Subsequent SMI requests are not acknowledged while the processor is in SMM. The first SMI interrupt request that occurs while the processor is in SMM (that is, after SMM has been acknowledged to external hardware) is latched and serviced when the processor exits SMM with the RSM instruction. The processor will latch only one SMI while in SMM.

See Section 34.5 for a detailed description of the execution environment when in SMM.

### 34.3.2 Exiting From SMM

The only way to exit SMM is to execute the RSM instruction. The RSM instruction is only available to the SMI handler; if the processor is not in SMM, attempts to execute the RSM instruction result in an invalid-opcode exception (#UD) being generated.

The RSM instruction restores the processor's context by loading the state save image from SMRAM back into the processor's registers. The processor then returns an SMIACK transaction on the system bus and returns program control back to the interrupted program.

Upon successful completion of the RSM instruction, the processor signals external hardware that SMM has been exited. For the P6 family processors, an SMI acknowledge transaction is generated on the system bus and the multiplexed status signal EXF4 is no longer generated on bus cycles. For the Pentium and Intel486 processors, the SMIACT# pin is deserted.

If the processor detects invalid state information saved in the SMRAM, it enters the shutdown state and generates a special bus cycle to indicate it has entered shutdown state. Shutdown happens only in the following situations:

- A reserved bit in control register CR4 is set to 1 on a write to CR4. This error should not happen unless SMI handler code modifies reserved areas of the SMRAM saved state map (see Section 34.4.1). CR4 is saved in the state map in a reserved location and cannot be read or modified in its saved state.
- An illegal combination of bits is written to control register CR0, in particular PG set to 1 and PE set to 0, or NW set to 1 and CD set to 0.
- CR4.PCIDE would be set to 1 and IA32_EFER.LMA to 0.
- (For the Pentium and Intel486 processors only.) If the address stored in the SMBASE register when an RSM instruction is executed is not aligned on a 32-KByte boundary. This restriction does not apply to the P6 family processors.

In the shutdown state, Intel processors stop executing instructions until a RESET#, INIT# or NMI# is asserted. While Pentium family processors recognize the SMI# signal in shutdown state, P6 family and Intel486 processors do not. Intel does not support using SMI# to recover from shutdown states for any processor family; the response of processors in this circumstance is not well defined. On Pentium 4 and later processors, shutdown will inhibit INTR and A20M but will not change any of the other inhibits. On these processors, NMIs will be inhibited if no action is taken in the SMI handler to uninhibit them (see Section 34.8).

If the processor is in the HALT state when the SMI is received, the processor handles the return from SMM slightly differently (see Section 34.10). Also, the SMBASE address can be changed on a return from SMM (see Section 34.11).

## 34.4 SMRAM

Upon entering SMM, the processor switches to a new address space. Because paging is disabled upon entering SMM, this initial address space maps all memory accesses to the low 4 GBytes of the processor's physical address space. The SMI handler's critical code and data reside in a memory region referred to as system-management RAM (SMRAM). The processor uses a pre-defined region within SMRAM to save the processor's pre-SMI context. SMRAM can also be used to store system management information (such as the system configuration and specific information about powered-down devices) and OEM-specific information.

The default SMRAM size is 64 KBytes beginning at a base physical address in physical memory called the SMBASE (see Figure 34-1). The SMBASE default value following a hardware reset is 30000H. The processor looks for the first instruction of the SMI handler at the address [SMBASE + 8000H]. It stores the processor's state in the area from [SMBASE + FE00H] to [SMBASE + FFFFH]. See Section 34.4.1 for a description of the mapping of the state save area.

The system logic is minimally required to decode the physical address range for the SMRAM from [SMBASE + 8000H] to [SMBASE + FFFFH]. A larger area can be decoded if needed. The size of this SMRAM can be between 32 KBytes and 4 GBytes.

The location of the SMRAM can be changed by changing the SMBASE value (see Section 34.11). It should be noted that all processors in a multiple-processor system are initialized with the same SMBASE value (30000H). Initialization software must sequentially place each processor in SMM and change its SMBASE so that it does not overlap those of other processors.

The actual physical location of the SMRAM can be in system memory or in a separate RAM memory. The processor generates an SMI acknowledge transaction (P6 family processors) or asserts the SMIACT# pin (Pentium and Intel486 processors) when the processor receives an SMI (see Section 34.3.1).

System logic can use the SMI acknowledge transaction or the assertion of the SMIACT# pin to decode accesses to the SMRAM and redirect them (if desired) to specific SMRAM memory. If a separate RAM memory is used for SMRAM, system logic should provide a programmable method of mapping the SMRAM into system memory space when the processor is not in SMM. This mechanism will enable start-up procedures to initialize the SMRAM space (that is, load the SMI handler) before executing the SMI handler during SMM.

### 34.4.1 SMRAM State Save Map

When an IA-32 processor that does not support Intel 64 architecture initially enters SMM, it writes its state to the state save area of the SMRAM. The state save area begins at [SMBASE + 8000H + 7FFFH] and extends down to [SMBASE + 8000H + 7E00H]. Table 34-1 shows the state save map. The offset in column 1 is relative to the SMBASE value plus 8000H. Reserved spaces should not be used by software.

Some of the registers in the SMRAM state save area (marked YES in column 3) may be read and changed by the SMI handler, with the changed values restored to the processor registers by the RSM instruction. Some register images are read-only, and must not be modified (modifying these registers will result in unpredictable behavior). An SMI handler should not rely on any values stored in an area that is marked as reserved.

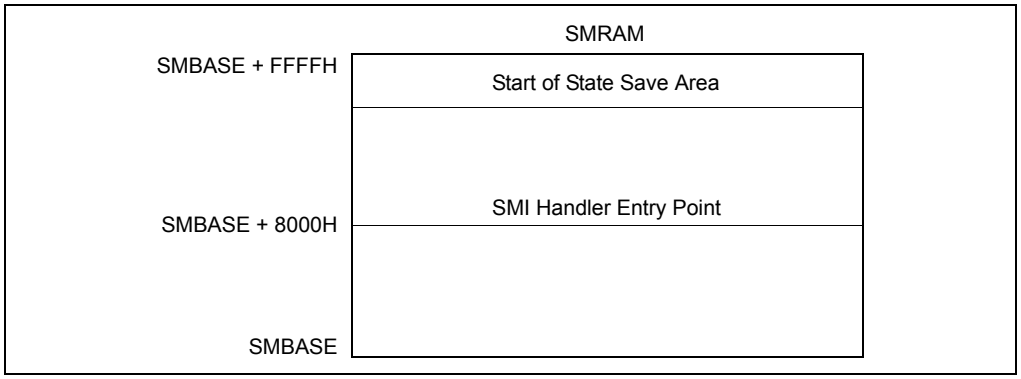

Figure 34-1. SMRAM Usage

**Table 34-1. SMRAM State Save Map**

| Offset (Added to SMBASE + 8000H) | Register | Writable? |
|---|---|---|
| 7FFCH | CR0 | No |
| 7FF8H | CR3 | No |
| 7FF4H | EFLAGS | Yes |
| 7FF0H | EIP | Yes |
| 7FECH | EDI | Yes |
| 7FE8H | ESI | Yes |
| 7FE4H | EBP | Yes |
| 7FE0H | ESP | Yes |
| 7FDCH | EBX | Yes |
| 7FD8H | EDX | Yes |
| 7FD4H | ECX | Yes |
| 7FD0H | EAX | Yes |
| 7FCCH | DR6 | No |
| 7FC8H | DR7 | No |
| 7FC4H | TR[1] | No |
| 7FC0H | Reserved | No |
| 7FBCH | GS[1] | No |
| 7FB8H | FS[1] | No |
| 7FB4H | DS[1] | No |
| 7FB0H | SS[1] | No |
| 7FACH | CS[1] | No |
| 7FA8H | ES[1] | No |
| 7FA4H | I/O State Field, see Section 34.7 | No |
| 7FA0H | I/O Memory Address Field, see Section 34.7 | No |
| 7F9FH-7F03H | Reserved | No |
| 7F02H | Auto HALT Restart Field (Word) | Yes |
| 7F00H | I/O Instruction Restart Field (Word) | Yes |
| 7EFCH | SMM Revision Identifier Field (Doubleword) | No |
| 7EF8H | SMBASE Field (Doubleword) | Yes |
| 7EF7H - 7E00H | Reserved | No |

NOTE:

1. The two most significant bytes are reserved.

The following registers are saved (but not readable) and restored upon exiting SMM:

- Control register CR4. (This register is cleared to all 0s when entering SMM).
- The hidden segment descriptor information stored in segment registers CS, DS, ES, FS, GS, and SS.

If an SMI request is issued for the purpose of powering down the processor, the values of all reserved locations in the SMM state save must be saved to nonvolatile memory.

The following state is not automatically saved and restored following an SMI and the RSM instruction, respectively:

- Debug registers DR0 through DR3.
- The x87 FPU registers.
- The MTRRs.
- Control register CR2.
- The model-specific registers (for the P6 family and Pentium processors) or test registers TR3 through TR7 (for the Pentium and Intel486 processors).
- The state of the trap controller.
- The machine-check architecture registers.
- The APIC internal interrupt state (ISR, IRR, etc.).
- The microcode update state.

If an SMI is used to power down the processor, a power-on reset will be required before returning to SMM, which will reset much of this state back to its default values. So an SMI handler that is going to trigger power down should first read these registers listed above directly, and save them (along with the rest of RAM) to nonvolatile storage. After the power-on reset, the continuation of the SMI handler should restore these values, along with the rest of the system's state. Anytime the SMI handler changes these registers in the processor, it must also save and restore them.

**NOTES**

A small subset of the MSRs (such as, the time-stamp counter and performance-monitoring counters) are not arbitrarily writable and therefore cannot be saved and restored. SMM-based power-down and restoration should only be performed with operating systems that do not use or rely on the values of these registers.

Operating system developers should be aware of this fact and insure that their operating-system assisted power-down and restoration software is immune to unexpected changes in these register values.

#### 34.4.1.1 SMRAM State Save Map and Intel 64 Architecture

When the processor initially enters SMM, it writes its state to the state save area of the SMRAM. The state save area on an Intel 64 processor at [SMBASE + 8000H + 7FFFH] and extends to [SMBASE + 8000H + 7C00H].

Support for Intel 64 architecture is reported by CPUID.80000001:EDX[29] = 1. The layout of the SMRAM state save map is shown in Table 34-3.

Additionally, the SMRAM state save map shown in Table 34-3 also applies to processors with the following CPUID signatures listed in Table 34-2, irrespective of the value in CPUID.80000001:EDX[29].

**Table 34-2. Processor Signatures and 64-bit SMRAM State Save Map Format**

| DisplayFamily_DisplayModel | Processor Families/Processor Number Series |
|---|---|
| **06_17H** | Intel Xeon Processor 5200, 5400 series, Intel Core 2 Quad processor Q9xxx, Intel Core 2 Duo processors E8000, T9000, |
| **06_0FH** | Intel Xeon Processor 3000, 3200, 5100, 5300, 7300 series, Intel Core 2 Quad, Intel Core 2 Extreme, Intel Core 2 Duo processors, Intel Pentium dual-core processors |
| **06_1CH** | Intel® Atom™ processors |

### Table 34-3. SMRAM State Save Map for Intel 64 Architecture

| Offset (Added to SMBASE + 8000H) | Register | Writable? |
|---|---|---|
| 7FF8H | CR0 | No |
| 7FF0H | CR3 | No |
| 7FE8H | RFLAGS | Yes |
| 7FE0H | IA32_EFER | Yes |

| 7E8BH - 7E44H | Reserved | No |
| 7E40H | CR4 | No |
| 7E3FH - 7DF0H | Reserved | No |
| 7DE8H | IO_RIP | Yes |
| 7DE7H - 7DDCH | Reserved | No |
| 7DD8H | IDT Base (Upper 32 bits) | No |
| 7DD4H | LDT Base (Upper 32 bits) | No |
| 7DD0H | GDT Base (Upper 32 bits) | No |
| 7DCFH - 7C00H | Reserved | No |

NOTE:

1. The two most significant bytes are reserved.

## 34.4.2 SMRAM Caching

An IA-32 processor does not automatically write back and invalidate its caches before entering SMM or before exiting SMM. Because of this behavior, care must be taken in the placement of the SMRAM in system memory and in the caching of the SMRAM to prevent cache incoherence when switching back and forth between SMM and protected mode operation. Either of the following three methods of locating the SMRAM in system memory will guarantee cache coherency:

- Place the SRAM in a dedicated section of system memory that the operating system and applications are prevented from accessing. Here, the SRAM can be designated as cacheable (WB, WT, or WC) for optimum processor performance, without risking cache incoherence when entering or exiting SMM.
- Place the SRAM in a section of memory that overlaps an area used by the operating system (such as the video memory), but designate the SMRAM as uncacheable (UC). This method prevents cache access when in SMM to maintain cache coherency, but the use of uncacheable memory reduces the performance of SMM code.
- Place the SRAM in a section of system memory that overlaps an area used by the operating system and/or application code, but explicitly flush (write back and invalidate) the caches upon entering and exiting SMM mode. This method maintains cache coherency, but incurs the overhead of two complete cache flushes.

For Pentium 4, Intel Xeon, and P6 family processors, a combination of the first two methods of locating the SMRAM is recommended. Here the SMRAM is split between an overlapping and a dedicated region of memory. Upon entering SMM, the SMRAM space that is accessed overlaps video memory (typically located in low memory). This SMRAM section is designated as UC memory. The initial SMM code then jumps to a second SMRAM section that is located in a dedicated region of system memory (typically in high memory). This SMRAM section can be cached for optimum processor performance.

For systems that explicitly flush the caches upon entering SMM (the third method described above), the cache flush can be accomplished by asserting the FLUSH# pin at the same time as the request to enter SMM (generally initiated by asserting the SMI# pin). The priorities of the FLUSH# and SMI# pins are such that the FLUSH# is serviced first. To guarantee this behavior, the processor requires that the following constraints on the interaction of FLUSH# and SMI# be met. In a system where the FLUSH# and SMI# pins are synchronous and the set up and hold times are met, then the FLUSH# and SMI# pins may be asserted in the same clock. In asynchronous systems, the FLUSH# pin must be asserted at least one clock before the SMI# pin to guarantee that the FLUSH# pin is serviced first.

Upon leaving SMM (for systems that explicitly flush the caches), the WBINVD instruction should be executed prior to leaving SMM to flush the caches.

**NOTES**

In systems based on the Pentium processor that use the FLUSH# pin to write back and invalidate cache contents before entering SMM, the processor will prefetch at least one cache line in between when the Flush Acknowledge cycle is run and the subsequent recognition of SMI# and the assertion of SMIACT#.

It is the obligation of the system to ensure that these lines are not cached by returning KEN# inactive to the Pentium processor.

#### 34.4.2.1 System Management Range Registers (SMRR)

SMI handler code and data stored by SMM code resides in SMRAM. The SMRR interface is an enhancement in Intel 64 architecture to limit cacheable reference of addresses in SMRAM to code running in SMM. The SMRR interface can be configured only by code running in SMM. Details of SMRR is described in Section 11.11.2.4.

## 34.5 SMI HANDLER EXECUTION ENVIRONMENT

Section 34.5.1 describes the initial execution environment for an SMI handler. An SMI handler may re-configure its execution environment to other supported operating modes. Section 34.5.2 discusses modifications an SMI handler can make to its execution environment.

### 34.5.1 Initial SMM Execution Environment

After saving the current context of the processor, the processor initializes its core registers to the values shown in Table 34-4. Upon entering SMM, the PE and PG flags in control register CR0 are cleared, which places the processor in an environment similar to real-address mode. The differences between the SMM execution environment and the real-address mode execution environment are as follows:

- The addressable address space ranges from 0 to FFFFFFFFH (4 GBytes).
- The normal 64-KByte segment limit for real-address mode is increased to 4 GBytes.
- The default operand and address sizes are set to 16 bits, which restricts the addressable SMRAM address space to the 1-MByte real-address mode limit for native real-address-mode code. However, operand-size and address-size override prefixes can be used to access the address space beyond the 1-MByte.

**Table 34-4. Processor Register Initialization in SMM**

| Register | Contents |
|---|---|
| General-purpose registers | Undefined |
| EFLAGS | 00000002H |
| EIP | 00008000H |
| CS selector | SMM Base shifted right 4 bits (default 3000H) |
| CS base | SMM Base (default 30000H) |
| DS, ES, FS, GS, SS Selectors | 0000H |

Table 34-4. Processor Register Initialization in SMM

| | |
|---|---|
| DS, ES, FS, GS, SS Bases | 000000000H |
| DS, ES, FS, GS, SS Limits | 0FFFFFFFFH |
| CR0 | PE, EM, TS, and PG flags set to 0; others unmodified |
| CR4 | Cleared to zero |
| DR6 | Undefined |
| DR7 | 00000400H |

- Near jumps and calls can be made to anywhere in the 4-GByte address space if a 32-bit operand-size override prefix is used. Due to the real-address-mode style of base-address formation, a far call or jump cannot transfer control to a segment with a base address of more than 20 bits (1 MByte). However, since the segment limit in SMM is 4 GBytes, offsets into a segment that go beyond the 1-MByte limit are allowed when using 32-bit operand-size override prefixes. Any program control transfer that does not have a 32-bit operand-size override prefix truncates the EIP value to the 16 low-order bits.
- Data and the stack can be located anywhere in the 4-GByte address space, but can be accessed only with a 32-bit address-size override if they are located above 1 MByte. As with the code segment, the base address for a data or stack segment cannot be more than 20 bits.

The value in segment register CS is automatically set to the default of 30000H for the SMBASE shifted 4 bits to the right; that is, 3000H. The EIP register is set to 8000H. When the EIP value is added to shifted CS value (the SMBASE), the resulting linear address points to the first instruction of the SMI handler.

The other segment registers (DS, SS, ES, FS, and GS) are cleared to 0 and their segment limits are set to 4 GBytes. In this state, the SMRAM address space may be treated as a single flat 4-GByte linear address space. If a segment register is loaded with a 16-bit value, that value is then shifted left by 4 bits and loaded into the segment base (hidden part of the segment register). The limits and attributes are not modified.

Maskable hardware interrupts, exceptions, NMI interrupts, SMI interrupts, A20M interrupts, single-step traps, breakpoint traps, and INIT operations are inhibited when the processor enters SMM. Maskable hardware interrupts, exceptions, single-step traps, and breakpoint traps can be enabled in SMM if the SMM execution environment provides and initializes an interrupt table and the necessary interrupt and exception handlers (see Section 34.6).

### 34.5.2 SMI Handler Operating Mode Switching

Within SMM, an SMI handler may change the processor's operating mode (e.g., to enable PAE paging, enter 64-bit mode, etc.) after it has made proper preparation and initialization to do so. For example, if switching to 32-bit protected mode, the SMI handler should follow the guidelines provided in Chapter 9, "Processor Management and Initialization". If the SMI handler does wish to change operating mode, it is responsible for executing the appropriate mode-transition code after each SMI.

It is recommended that the SMI handler make use of all means available to protect the integrity of its critical code and data. In particular, it should use the system-management range register (SMRR) interface if it is available (see Section 11.11.2.4). The SMRR interface can protect only the first 4 GBytes of the physical address space. The SMI handler should take that fact into account if it uses operating modes that allow access to physical addresses beyond that 4-GByte limit (e.g. PAE paging or 64-bit mode).

Execution of the RSM instruction restores the pre-SMI processor state from the SMRAM state-state map (see Section 34.4.1) into which it was stored when the processor entered SMM. (The SMBASE field in the SMRAM state-save map does not determine the state following RSM but rather the initial environment following the next entry to SMM.) Any required change to operating mode is performed by the RSM instruction; there is no need for the SMI handler to change modes explicitly prior to executing RSM.

## 34.6 EXCEPTIONS AND INTERRUPTS WITHIN SMM

When the processor enters SMM, all hardware interrupts are disabled in the following manner:

- The IF flag in the EFLAGS register is cleared, which inhibits maskable hardware interrupts from being generated.
- The TF flag in the EFLAGS register is cleared, which disables single-step traps.
- Debug register DR7 is cleared, which disables breakpoint traps. (This action prevents a debugger from accidentally breaking into an SMI handler if a debug breakpoint is set in normal address space that overlays code or data in SMRAM.)
- NMI, SMI, and A20M interrupts are blocked by internal SMM logic. (See Section 34.8 for more information about how NMIs are handled in SMM.)

Software-invoked interrupts and exceptions can still occur, and maskable hardware interrupts can be enabled by setting the IF flag. Intel recommends that SMM code be written in so that it does not invoke software interrupts (with the INT *n*, INTO, INT 3, or BOUND instructions) or generate exceptions.

If the SMI handler requires interrupt and exception handling, an SMM interrupt table and the necessary exception and interrupt handlers must be created and initialized from within SMM. Until the interrupt table is correctly initialized (using the LIDT instruction), exceptions and software interrupts will result in unpredictable processor behavior.

The following restrictions apply when designing SMM interrupt and exception-handling facilities:

- The interrupt table should be located at linear address 0 and must contain real-address mode style interrupt vectors (4 bytes containing CS and IP).
- Due to the real-address mode style of base address formation, an interrupt or exception cannot transfer control to a segment with a base address of more that 20 bits.
- An interrupt or exception cannot transfer control to a segment offset of more than 16 bits (64 KBytes).
- When an exception or interrupt occurs, only the 16 least-significant bits of the return address (EIP) are pushed onto the stack. If the offset of the interrupted procedure is greater than 64 KBytes, it is not possible for the interrupt/exception handler to return control to that procedure. (One solution to this problem is for a handler to adjust the return address on the stack.)
- The SMBASE relocation feature affects the way the processor will return from an interrupt or exception generated while the SMI handler is executing. For example, if the SMBASE is relocated to above 1 MByte, but the exception handlers are below 1 MByte, a normal return to the SMI handler is not possible. One solution is to provide the exception handler with a mechanism for calculating a return address above 1 MByte from the 16-bit return address on the stack, then use a 32-bit far call to return to the interrupted procedure.
- If an SMI handler needs access to the debug trap facilities, it must insure that an SMM accessible debug handler is available and save the current contents of debug registers DR0 through DR3 (for later restoration). Debug registers DR0 through DR3 and DR7 must then be initialized with the appropriate values.
- If an SMI handler needs access to the single-step mechanism, it must insure that an SMM accessible single-step handler is available, and then set the TF flag in the EFLAGS register.
- If the SMI design requires the processor to respond to maskable hardware interrupts or software-generated interrupts while in SMM, it must ensure that SMM accessible interrupt handlers are available and then set the IF flag in the EFLAGS register (using the STI instruction). Software interrupts are not blocked upon entry to SMM, so they do not need to be enabled.

## 34.7 MANAGING SYNCHRONOUS AND ASYNCHRONOUS SYSTEM MANAGEMENT INTERRUPTS

When coding for a multiprocessor system or a system with Intel HT Technology, it was not always possible for an SMI handler to distinguish between a synchronous SMI (triggered during an I/O instruction) and an asynchronous SMI. To facilitate the discrimination of these two events, incremental state information has been added to the SMM state save map.

Processors that have an SMM revision ID of 30004H or higher have the incremental state information described below.

### 34.7.1 I/O State Implementation

Within the extended SMM state save map, a bit (IO_SMI) is provided that is set only when an SMI is either taken immediately after a *successful* I/O instruction or is taken after a *successful* iteration of a REP I/O instruction (the *successful* notion pertains to the processor point of view; not necessarily to the corresponding platform function). When set, the IO_SMI bit provides a strong indication that the corresponding SMI was synchronous. In this case, the SMM State Save Map also supplies the port address of the I/O operation. The IO_SMI bit and the I/O Port Address may be used in conjunction with the information logged by the platform to confirm that the SMI was indeed synchronous.

The IO_SMI bit by itself is a strong indication, not a guarantee, that the SMI is synchronous. This is because an asynchronous SMI might coincidentally be taken after an I/O instruction. In such a case, the IO_SMI bit would still be set in the SMM state save map.

Information characterizing the I/O instruction is saved in two locations in the SMM State Save Map (Table 34-5). The IO_SMI bit also serves as a valid bit for the rest of the I/O information fields. The contents of these I/O information fields are not defined when the IO_SMI bit is not set.

**Table 34-5. I/O Instruction Information in the SMM State Save Map**

| State (SMM Rev. ID: 30004H or higher) | Format | | | | |
|---|---|---|---|---|---|
| | 31 16 | 15 8 | 7 4 | 3 1 | 0 |
| I/O State Field<br>SMRAM offset 7FA4 | I/O Port | Reserved | I/O Type | I/O Length | IO_SMI |
| | 31 | | | | 0 |
| I/O Memory Address Field<br>SMRAM offset 7FA0 | I/O Memory Address | | | | |

When IO_SMI is set, the other fields may be interpreted as follows:

- I/O length:
  - 001 – Byte
  - 010 – Word
  - 100 – Dword
- I/O instruction type (Table 34-6)

**Table 34-6. I/O Instruction Type Encodings**

| Instruction | Encoding |
|---|---|
| IN Immediate | 1001 |
| IN DX | 0001 |
| OUT Immediate | 1000 |
| OUT DX | 0000 |
| INS | 0011 |
| OUTS | 0010 |
| REP INS | 0111 |
| REP OUTS | 0110 |

## 34.8 NMI HANDLING WHILE IN SMM

NMI interrupts are blocked upon entry to the SMI handler. If an NMI request occurs during the SMI handler, it is latched and serviced after the processor exits SMM. Only one NMI request will be latched during the SMI handler. If an NMI request is pending when the processor executes the RSM instruction, the NMI is serviced before the next instruction of the interrupted code sequence. This assumes that NMIs were not blocked before the SMI occurred. If NMIs were blocked before the SMI occurred, they are blocked after execution of RSM.

Although NMI requests are blocked when the processor enters SMM, they may be enabled through software by executing an IRET instruction. If the SMI handler requires the use of NMI interrupts, it should invoke a dummy interrupt service routine for the purpose of executing an IRET instruction. Once an IRET instruction is executed, NMI interrupt requests are serviced in the same "real mode" manner in which they are handled outside of SMM.

A special case can occur if an SMI handler nests inside an NMI handler and then another NMI occurs. During NMI interrupt handling, NMI interrupts are disabled, so normally NMI interrupts are serviced and completed with an IRET instruction one at a time. When the processor enters SMM while executing an NMI handler, the processor saves the SMRAM state save map but does not save the attribute to keep NMI interrupts disabled. Potentially, an NMI could be latched (while in SMM or upon exit) and serviced upon exit of SMM even though the previous NMI handler has still not completed. One or more NMIs could thus be nested inside the first NMI handler. The NMI interrupt handler should take this possibility into consideration.

Also, for the Pentium processor, exceptions that invoke a trap or fault handler will enable NMI interrupts from inside of SMM. This behavior is implementation specific for the Pentium processor and is not part of the IA-32 architecture.

## 34.9 SMM REVISION IDENTIFIER

The SMM revision identifier field is used to indicate the version of SMM and the SMM extensions that are supported by the processor (see Figure 34-2). The SMM revision identifier is written during SMM entry and can be examined in SMRAM space at offset 7EFCH. The lower word of the SMM revision identifier refers to the version of the base SMM architecture.

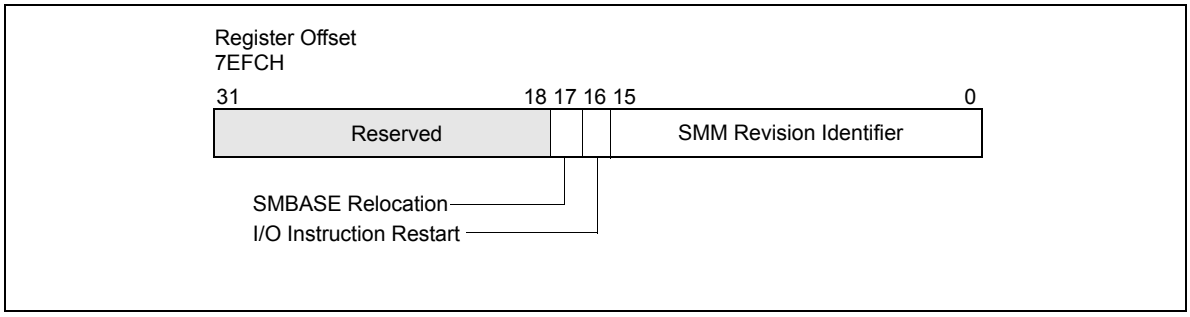

**Figure 34-2. SMM Revision Identifier**

The upper word of the SMM revision identifier refers to the extensions available. If the I/O instruction restart flag (bit 16) is set, the processor supports the I/O instruction restart (see Section 34.12); if the SMBASE relocation flag (bit 17) is set, SMRAM base address relocation is supported (see Section 34.11).

## 34.10 AUTO HALT RESTART

If the processor is in a HALT state (due to the prior execution of a HLT instruction) when it receives an SMI, the processor records the fact in the auto HALT restart flag in the saved processor state (see Figure 34-3). (This flag is located at offset 7F02H and bit 0 in the state save area of the SMRAM.)

If the processor sets the auto HALT restart flag upon entering SMM (indicating that the SMI occurred when the processor was in the HALT state), the SMI handler has two options:

- It can leave the auto HALT restart flag set, which instructs the RSM instruction to return program control to the HLT instruction. This option in effect causes the processor to re-enter the HALT state after handling the SMI. (This is the default operation.)
- It can clear the auto HALT restart flag, which instructs the RSM instruction to return program control to the instruction following the HLT instruction.

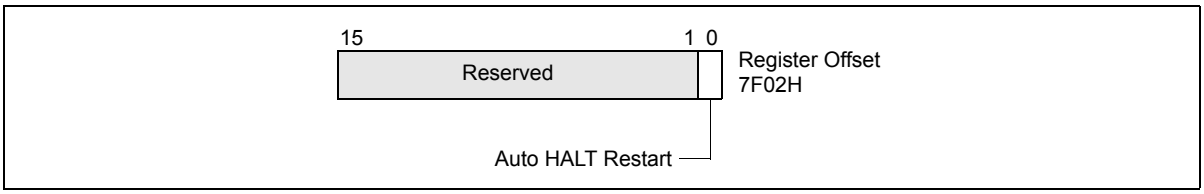

**Figure 34-3. Auto HALT Restart Field**

These options are summarized in Table 34-7. If the processor was not in a HALT state when the SMI was received (the auto HALT restart flag is cleared), setting the flag to 1 will cause unpredictable behavior when the RSM instruction is executed.

**Table 34-7. Auto HALT Restart Flag Values**

| Value of Flag After Entry to SMM | Value of Flag When Exiting SMM | Action of Processor When Exiting SMM |
|---|---|---|
| 0 | 0 | Returns to next instruction in interrupted program or task. |
| 0 | 1 | Unpredictable. |
| 1 | 0 | Returns to next instruction after HLT instruction. |
| 1 | 1 | Returns to HALT state. |

If the HLT instruction is restarted, the processor will generate a memory access to fetch the HLT instruction (if it is not in the internal cache), and execute a HLT bus transaction. This behavior results in multiple HLT bus transactions for the same HLT instruction.

### 34.10.1 Executing the HLT Instruction in SMM

The HLT instruction should not be executed during SMM, unless interrupts have been enabled by setting the IF flag in the EFLAGS register. If the processor is halted in SMM, the only event that can remove the processor from this state is a maskable hardware interrupt or a hardware reset.

## 34.11 SMBASE RELOCATION

The default base address for the SMRAM is 30000H. This value is contained in an internal processor register called the SMBASE register. The operating system or executive can relocate the SMRAM by setting the SMBASE field in the saved state map (at offset 7EF8H) to a new value (see Figure 34-4). The RSM instruction reloads the internal SMBASE register with the value in the SMBASE field each time it exits SMM. All subsequent SMI requests will use the new SMBASE value to find the starting address for the SMI handler (at SMBASE + 8000H) and the SMRAM state save area (from SMBASE + FE00H to SMBASE + FFFFH). (The processor resets the value in its internal SMBASE register to 30000H on a RESET, but does not change it on an INIT.)

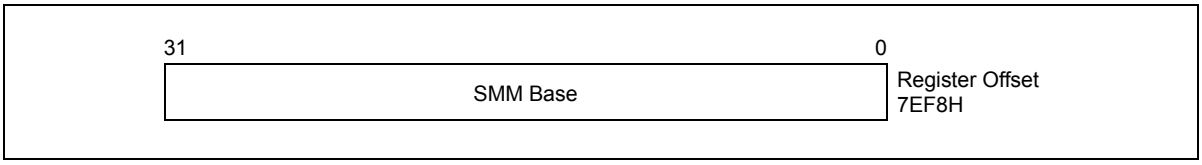

Figure 34-4. SMBASE Relocation Field

In multiple-processor systems, initialization software must adjust the SMBASE value for each processor so that the SMRAM state save areas for each processor do not overlap. (For Pentium and Intel486 processors, the SMBASE values must be aligned on a 32-KByte boundary or the processor will enter shutdown state during the execution of a RSM instruction.)

If the SMBASE relocation flag in the SMM revision identifier field is set, it indicates the ability to relocate the SMBASE (see Section 34.9).

## 34.12 I/O INSTRUCTION RESTART

If the I/O instruction restart flag in the SMM revision identifier field is set (see Section 34.9), the I/O instruction restart mechanism is present on the processor. This mechanism allows an interrupted I/O instruction to be re-executed upon returning from SMM mode. For example, if an I/O instruction is used to access a powered-down I/O device, a chip set supporting this device can intercept the access and respond by asserting SMI#. This action invokes the SMI handler to power-up the device. Upon returning from the SMI handler, the I/O instruction restart mechanism can be used to re-execute the I/O instruction that caused the SMI.

The I/O instruction restart field (at offset 7F00H in the SMM state-save area, see Figure 34-5) controls I/O instruction restart. When an RSM instruction is executed, if this field contains the value FFH, then the EIP register is modified to point to the I/O instruction that received the SMI request. The processor will then automatically re-execute the I/O instruction that the SMI trapped. (The processor saves the necessary machine state to insure that re-execution of the instruction is handled coherently.)

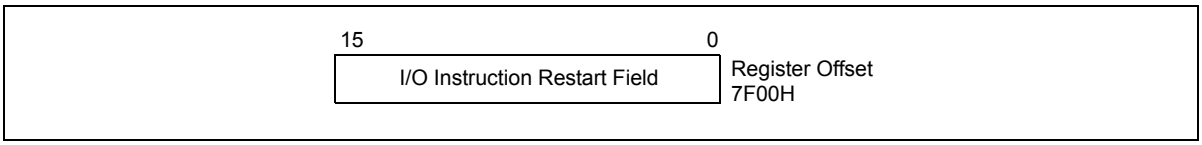

Figure 34-5. I/O Instruction Restart Field

If the I/O instruction restart field contains the value 00H when the RSM instruction is executed, then the processor begins program execution with the instruction following the I/O instruction. (When a repeat prefix is being used, the next instruction may be the next I/O instruction in the repeat loop.) Not re-executing the interrupted I/O instruction is the default behavior; the processor automatically initializes the I/O instruction restart field to 00H upon entering SMM. Table 34-8 summarizes the states of the I/O instruction restart field.

Table 34-8. I/O Instruction Restart Field Values

| Value of Flag After Entry to SMM | Value of Flag When Exiting SMM | Action of Processor When Exiting SMM |
|---|---|---|
| 00H | 00H | Does not re-execute trapped I/O instruction. |
| 00H | FFH | Re-executes trapped I/O instruction. |

The I/O instruction restart mechanism does not indicate the cause of the SMI. It is the responsibility of the SMI handler to examine the state of the processor to determine the cause of the SMI and to determine if an I/O instruction was interrupted and should be restarted upon exiting SMM. If an SMI interrupt is signaled on a non-I/O instruction boundary, setting the I/O instruction restart field to FFH prior to executing the RSM instruction will likely result in a program error.

### 34.12.1 Back-to-Back SMI Interrupts When I/O Instruction Restart Is Being Used

If an SMI interrupt is signaled while the processor is servicing an SMI interrupt that occurred on an I/O instruction boundary, the processor will service the new SMI request before restarting the originally interrupted I/O instruction. If the I/O instruction restart field is set to FFH prior to returning from the second SMI handler, the EIP will point to an address different from the originally interrupted I/O instruction, which will likely lead to a program error. To avoid this situation, the SMI handler must be able to recognize the occurrence of back-to-back SMI interrupts when I/O instruction restart is being used and insure that the handler sets the I/O instruction restart field to 00H prior to returning from the second invocation of the SMI handler.

## 34.13 SMM MULTIPLE-PROCESSOR CONSIDERATIONS

The following should be noted when designing multiple-processor systems:

- Any processor in a multiprocessor system can respond to an SMM.
- Each processor needs its own SMRAM space. This space can be in system memory or in a separate RAM.
- The SMRAMs for different processors can be overlapped in the same memory space. The only stipulation is that each processor needs its own state save area and its own dynamic data storage area. (Also, for the Pentium and Intel486 processors, the SMBASE address must be located on a 32-KByte boundary.) Code and static data can be shared among processors. Overlapping SMRAM spaces can be done more efficiently with the P6 family processors because they do not require that the SMBASE address be on a 32-KByte boundary.
- The SMI handler will need to initialize the SMBASE for each processor.
- Processors can respond to local SMIs through their SMI# pins or to SMIs received through the APIC interface. The APIC interface can distribute SMIs to different processors.
- Two or more processors can be executing in SMM at the same time.
- When operating Pentium processors in dual processing (DP) mode, the SMIACT# pin is driven only by the MRM processor and should be sampled with ADS#. For additional details, see Chapter 14 of the *Pentium Processor Family User's Manual, Volume 1*.

SMM is not re-entrant, because the SMRAM State Save Map is fixed relative to the SMBASE. If there is a need to support two or more processors in SMM mode at the same time then each processor should have dedicated SMRAM spaces. This can be done by using the SMBASE Relocation feature (see Section 34.11).

## 34.14 DEFAULT TREATMENT OF SMIS AND SMM WITH VMX OPERATION AND SMX OPERATION

Under the default treatment, the interactions of SMIs and SMM with VMX operation are few. This section details those interactions. It also explains how this treatment affects SMX operation.

### 34.14.1 Default Treatment of SMI Delivery

Ordinary SMI delivery saves processor state into SMRAM and then loads state based on architectural definitions. Under the default treatment, processors that support VMX operation perform SMI delivery as follows:

```
enter SMM;
save the following internal to the processor:
    CR4.VMXE
    an indication of whether the logical processor was in VMX operation (root or non-root)
IF the logical processor is in VMX operation
    THEN
        save current VMCS pointer internal to the processor;
        leave VMX operation;
        save VMX-critical state defined below;
```

```
FI;
IF the logical processor supports SMX operation
    THEN
        save internal to the logical processor an indication of whether the Intel® TXT private space is locked;
        IF the TXT private space is unlocked
            THEN lock the TXT private space;
        FI;
FI;
CR4.VMXE ← 0;
perform ordinary SMI delivery:
    save processor state in SMRAM;
    set processor state to standard SMM values;[1]
    invalidate linear mappings and combined mappings associated with VPID 0000H (for all PCIDs); combined mappings for VPID 0000H
are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 28.3);
```

The pseudocode above makes reference to the saving of **VMX-critical state**. This state consists of the following: (1) SS.DPL (the current privilege level); (2) RFLAGS.VM[2]; (3) the state of blocking by STI and by MOV SS (see Table 24-3 in Section 24.4.2); (4) the state of virtual-NMI blocking (only if the processor is in VMX non-root operation and the "virtual NMIs" VM-execution control is 1); and (5) an indication of whether an MTF VM exit is pending (see Section 25.5.2). These data may be saved internal to the processor or in the VMCS region of the current VMCS. Processors that do not support SMI recognition while there is blocking by STI or by MOV SS need not save the state of such blocking.

If the logical processor supports the 1-setting of the "enable EPT" VM-execution control and the logical processor was in VMX non-root operation at the time of an SMI, it saves the value of that control into bit 0 of the 32-bit field at offset SMBASE + 8000H + 7EE0H (SMBASE + FEE0H; see Table 34-3).[3] If the logical processor was not in VMX non-root operation at the time of the SMI, it saves 0 into that bit. If the logical processor saves 1 into that bit (it was in VMX non-root operation and the "enable EPT" VM-execution control was 1), it saves the value of the EPT pointer (EPTP) into the 64-bit field at offset SMBASE + 8000H + 7ED8H (SMBASE + FED8H).

Because SMI delivery causes a logical processor to leave VMX operation, all the controls associated with VMX non-root operation are disabled in SMM and thus cannot cause VM exits while the logical processor in SMM.

## 34.14.2 Default Treatment of RSM

Ordinary execution of RSM restores processor state from SMRAM. Under the default treatment, processors that support VMX operation perform RSM as follows:

```
IF VMXE = 1 in CR4 image in SMRAM
    THEN fail and enter shutdown state;
    ELSE
        restore state normally from SMRAM;
        invalidate linear mappings and combined mappings associated with all VPIDs and all PCIDs; combined mappings are invalidated
for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 28.3);
        IF the logical processor supports SMX operation andthe Intel® TXT private space was unlocked at the time of the last SMI (as
saved)
            THEN unlock the TXT private space;
        FI;
        CR4.VMXE ← value stored internally;
```

1. This causes the logical processor to block INIT signals, NMIs, and SMIs.
2. Section 34.14 and Section 34.15 use the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of these registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to the lower 32 bits of the register.
3. "Enable EPT" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, SMI functions as the "enable EPT" VM-execution control were 0. See Section 24.6.2.

```
        IF internal storage indicates that the logical processor
        had been in VMX operation (root or non-root)
            THEN
                enter VMX operation (root or non-root);
                restore VMX-critical state as defined in Section 34.14.1;
                set to their fixed values any bits in CR0 and CR4 whose values must be fixed in VMX operation (see Section 23.8);[1]
                IF RFLAGS.VM = 0 AND (in VMX root operation OR the "unrestricted guest" VM-execution control is 0)[2]
                    THEN
                        CS.RPL ← SS.DPL;
                        SS.RPL ← SS.DPL;
                FI;
                restore current VMCS pointer;
        FI;
        leave SMM;
        IF logical processor will be in VMX operation or in SMX operation after RSM
            THEN block A20M and leave A20M mode;
        FI;
FI;
```

RSM unblocks SMIs. It restores the state of blocking by NMI (see Table 24-3 in Section 24.4.2) as follows:

- If the RSM is not to VMX non-root operation or if the "virtual NMIs" VM-execution control will be 0, the state of NMI blocking is restored normally.
- If the RSM is to VMX non-root operation and the "virtual NMIs" VM-execution control will be 1, NMIs are not blocked after RSM. The state of virtual-NMI blocking is restored as part of VMX-critical state.

INIT signals are blocked after RSM if and only if the logical processor will be in VMX root operation.

If RSM returns a logical processor to VMX non-root operation, it re-establishes the controls associated with the current VMCS. If the "interrupt-window exiting" VM-execution control is 1, a VM exit occurs immediately after RSM if the enabling conditions apply. The same is true for the "NMI-window exiting" VM-execution control. Such VM exits occur with their normal priority. See Section 25.2.

If an MTF VM exit was pending at the time of the previous SMI, an MTF VM exit is pending on the instruction boundary following execution of RSM. The following items detail the treatment of MTF VM exits that may be pending following RSM:

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over these MTF VM exits. These MTF VM exits take priority over debug-trap exceptions and lower priority events.
- These MTF VM exits wake the logical processor if RSM caused the logical processor to enter the HLT state (see Section 34.10). They do not occur if the logical processor just entered the shutdown state.

### 34.14.3 Protection of CR4.VMXE in SMM

Under the default treatment, CR4.VMXE is treated as a reserved bit while a logical processor is in SMM. Any attempt by software running in SMM to set this bit causes a general-protection exception. In addition, software cannot use VMX instructions or enter VMX operation while in SMM.

### 34.14.4 VMXOFF and SMI Unblocking

The VMXOFF instruction can be executed only with the default treatment (see Section 34.15.1) and only outside SMM. If SMIs are blocked when VMXOFF is executed, VMXOFF unblocks them unless

1. If the RSM is to VMX non-root operation and both the "unrestricted guest" VM-execution control and bit 31 of the primary processor-based VM-execution controls will be 1, CR0.PE and CR0.PG retain the values that were loaded from SMRAM regardless of what is reported in the capability MSR IA32_VMX_CR0_FIXED0.
2. "Unrestricted guest" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "unrestricted guest" VM-execution control were 0. See Section 24.6.2.

IA32_SMM_MONITOR_CTL[bit 2] is 1 (see Section 34.15.5 for details regarding this MSR).[1] Section 34.15.7 identifies a case in which SMIs may be blocked when VMXOFF is executed.

Not all processors allow this bit to be set to 1. Software should consult the VMX capability MSR IA32_VMX_MISC (see Appendix A.6) to determine whether this is allowed.

## 34.15 DUAL-MONITOR TREATMENT OF SMIs AND SMM

Dual-monitor treatment is activated through the cooperation of the **executive monitor** (the VMM that operates outside of SMM to provide basic virtualization) and the **SMM-transfer monitor** (**STM**; the VMM that operates inside SMM—while in VMX operation—to support system-management functions). Control is transferred to the STM through VM exits; VM entries are used to return from SMM.

The dual-monitor treatment may not be supported by all processors. Software should consult the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1) to determine whether it is supported.

### 34.15.1 Dual-Monitor Treatment Overview

The dual-monitor treatment uses an executive monitor and an SMM-transfer monitor (STM). Transitions from the executive monitor or its guests to the STM are called **SMM VM exits** and are discussed in Section 34.15.2. SMM VM exits are caused by SMIs as well as executions of VMCALL in VMX root operation. The latter allow the executive monitor to call the STM for service.

The STM runs in VMX root operation and uses VMX instructions to establish a VMCS and perform VM entries to its own guests. This is done all inside SMM (see Section 34.15.3). The STM returns from SMM, not by using the RSM instruction, but by using a VM entry that returns from SMM. Such VM entries are described in Section 34.15.4.

Initially, there is no STM and the default treatment (Section 34.14) is used. The dual-monitor treatment is not used until it is enabled and activated. The steps to do this are described in Section 34.15.5 and Section 34.15.6.

It is not possible to leave VMX operation under the dual-monitor treatment; VMXOFF will fail if executed. The dual-monitor treatment must be deactivated first. The STM deactivates dual-monitor treatment using a VM entry that returns from SMM with the "deactivate dual-monitor treatment" VM-entry control set to 1 (see Section 34.15.7).

The executive monitor configures any VMCS that it uses for VM exits to the executive monitor. SMM VM exits, which transfer control to the STM, use a different VMCS. Under the dual-monitor treatment, each logical processor uses a separate VMCS called the **SMM-transfer VMCS**. When the dual-monitor treatment is active, the logical processor maintains another VMCS pointer called the **SMM-transfer VMCS pointer**. The SMM-transfer VMCS pointer is established when the dual-monitor treatment is activated.

### 34.15.2 SMM VM Exits

An SMM VM exit is a VM exit that begins outside SMM and that ends in SMM.

Unlike other VM exits, SMM VM exits can begin in VMX root operation. SMM VM exits result from the arrival of an SMI outside SMM or from execution of VMCALL in VMX root operation outside SMM. Execution of VMCALL in VMX root operation causes an SMM VM exit only if the valid bit is set in the IA32_SMM_MONITOR_CTL MSR (see Section 34.15.5).

Execution of VMCALL in VMX root operation causes an SMM VM exit even under the default treatment. This SMM VM exit activates the dual-monitor treatment (see Section 34.15.6).

Differences between SMM VM exits and other VM exits are detailed in Sections 34.15.2.1 through 34.15.2.5. Differences between SMM VM exits that activate the dual-monitor treatment and other SMM VM exits are described in Section 34.15.6.

1. Setting IA32_SMM_MONITOR_CTL[bit 2] to 1 prevents VMXOFF from unblocking SMIs regardless of the value of the register's valid bit (bit 0).

### 34.15.2.1 Architectural State Before a VM Exit

System-management interrupts (SMIs) that cause SMM VM exits always do so directly. They do not save state to SMRAM as they do under the default treatment.

### 34.15.2.2 Updating the Current-VMCS and Executive-VMCS Pointers

SMM VM exits begin by performing the following steps:

1. The executive-VMCS pointer field in the SMM-transfer VMCS is loaded as follows:
   — If the SMM VM exit commenced in VMX non-root operation, it receives the current-VMCS pointer.
   — If the SMM VM exit commenced in VMX root operation, it receives the VMXON pointer.
2. The current-VMCS pointer is loaded with the value of the SMM-transfer VMCS pointer.

The last step ensures that the current VMCS is the SMM-transfer VMCS. VM-exit information is recorded in that VMCS, and VM-entry control fields in that VMCS are updated. State is saved into the guest-state area of that VMCS. The VM-exit controls and host-state area of that VMCS determine how the VM exit operates.

### 34.15.2.3 Recording VM-Exit Information

SMM VM exits differ from other VM exit with regard to the way they record VM-exit information. The differences follow.

- **Exit reason**.
  — Bits 15:0 of this field contain the basic exit reason. The field is loaded with the reason for the SMM VM exit: I/O SMI (an SMI arrived immediately after retirement of an I/O instruction), other SMI, or VMCALL. See Appendix C, “VMX Basic Exit Reasons”.
  — SMM VM exits are the only VM exits that may occur in VMX root operation. Because the SMM-transfer monitor may need to know whether it was invoked from VMX root or VMX non-root operation, this information is stored in bit 29 of the exit-reason field (see Table 24-14 in Section 24.9.1). The bit is set by SMM VM exits from VMX root operation.
  — If the SMM VM exit occurred in VMX non-root operation and an MTF VM exit was pending, bit 28 of the exit-reason field is set; otherwise, it is cleared.
  — Bits 27:16 and bits 31:30 are cleared.
- **Exit qualification.** For an SMM VM exit due an SMI that arrives immediately after the retirement of an I/O instruction, the exit qualification contains information about the I/O instruction that retired immediately before the SMI.It has the format given in Table 34-9.

**Table 34-9. Exit Qualification for SMIs That Arrive Immediately After the Retirement of an I/O Instruction**

| Bit Position(s) | Contents |
|---|---|
| 2:0 | Size of access:<br>0 = 1-byte<br>1 = 2-byte<br>3 = 4-byte<br><br>Other values not used. |
| 3 | Direction of the attempted access (0 = OUT, 1 = IN) |
| 4 | String instruction (0 = not string; 1 = string) |
| 5 | REP prefixed (0 = not REP; 1 = REP) |
| 6 | Operand encoding (0 = DX, 1 = immediate) |

**Table 34-9. Exit Qualification for SMIs That Arrive Immediately After the Retirement of an I/O Instruction (Contd.)**

| Bit Position(s) | Contents |
|---|---|
| 15:7 | Reserved (cleared to 0) |
| 31:16 | Port number (as specified in the I/O instruction) |
| 63:32 | Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture. |

- **Guest linear address.** This field is used for VM exits due to SMIs that arrive immediately after the retirement of an INS or OUTS instruction for which the relevant segment (ES for INS; DS for OUTS unless overridden by an instruction prefix) is usable. The field receives the value of the linear address generated by ES:(E)DI (for INS) or segment:(E)SI (for OUTS; the default segment is DS but can be overridden by a segment override prefix) at the time the instruction started. If the relevant segment is not usable, the value is undefined. On processors that support Intel 64 architecture, bits 63:32 are clear if the logical processor was not in 64-bit mode before the VM exit.
- **I/O RCX, I/O RSI, I/O RDI, and I/O RIP.** For an SMM VM exit due an SMI that arrives immediately after the retirement of an I/O instruction, these fields receive the values that were in RCX, RSI, RDI, and RIP, respectively, before the I/O instruction executed. Thus, the value saved for I/O RIP addresses the I/O instruction.

### 34.15.2.4 Saving Guest State

SMM VM exits save the contents of the SMBASE register into the corresponding field in the guest-state area.

The value of the VMX-preemption timer is saved into the corresponding field in the guest-state area if the "save VMX-preemption timer value" VM-exit control is 1. That field becomes undefined if, in addition, either the SMM VM exit is from VMX root operation or the SMM VM exit is from VMX non-root operation and the "activate VMX-preemption timer" VM-execution control is 0.

### 34.15.2.5 Updating Non-Register State

SMM VM exits affect the non-register state of a logical processor as follows:

- SMM VM exits cause non-maskable interrupts (NMIs) to be blocked; they may be unblocked through execution of IRET or through a VM entry (depending on the value loaded for the interruptibility state and the setting of the "virtual NMIs" VM-execution control).
- SMM VM exits cause SMIs to be blocked; they may be unblocked by a VM entry that returns from SMM (see Section 34.15.4).

SMM VM exits invalidate linear mappings and combined mappings associated with VPID 0000H for all PCIDs. Combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 28.3). (Ordinary VM exits are not required to perform such invalidation if the "enable VPID" VM-execution control is 1; see Section 27.5.5.)

## 34.15.3 Operation of the SMM-Transfer Monitor

Once invoked, the SMM-transfer monitor (STM) is in VMX root operation and can use VMX instructions to configure VMCSs and to cause VM entries to virtual machines supported by those structures. As noted in Section 34.15.1, the VMXOFF instruction cannot be used under the dual-monitor treatment and thus cannot be used by the STM.

The RSM instruction also cannot be used under the dual-monitor treatment. As noted in Section 25.1.3, it causes a VM exit if executed in SMM in VMX non-root operation. If executed in VMX root operation, it causes an invalid-opcode exception. The STM uses VM entries to return from SMM (see Section 34.15.4).

### 34.15.4 VM Entries that Return from SMM

The SMM-transfer monitor (STM) returns from SMM using a VM entry with the "entry to SMM" VM-entry control clear. VM entries that return from SMM reverse the effects of an SMM VM exit (see Section 34.15.2).

VM entries that return from SMM may differ from other VM entries in that they do not necessarily enter VMX non-root operation. If the executive-VMCS pointer field in the current VMCS contains the VMXON pointer, the logical processor remains in VMX root operation after VM entry.

For differences between VM entries that return from SMM and other VM entries see Sections 34.15.4.1 through 34.15.4.10.

#### 34.15.4.1 Checks on the Executive-VMCS Pointer Field

VM entries that return from SMM perform the following checks on the executive-VMCS pointer field in the current VMCS:

- Bits 11:0 must be 0.
- The pointer must not set any bits beyond the processor's physical-address width.[1,2]
- The 32 bits located in memory referenced by the physical address in the pointer must contain the processor's VMCS revision identifier (see Section 24.2).

The checks above are performed before the checks described in Section 34.15.4.2 and before any of the following checks:

- 'If the "deactivate dual-monitor treatment" VM-entry control is 0 and the executive-VMCS pointer field does not contain the VMXON pointer, the launch state of the executive VMCS (the VMCS referenced by the executive-VMCS pointer field) must be launched (see Section 24.11.3).
- If the "deactivate dual-monitor treatment" VM-entry control is 1, the executive-VMCS pointer field must contain the VMXON pointer (see Section 34.15.7).[3]

#### 34.15.4.2 Checks on VM-Execution Control Fields

VM entries that return from SMM differ from other VM entries with regard to the checks performed on the VM-execution control fields specified in Section 26.2.1.1. They do not apply the checks to the current VMCS. Instead, VM-entry behavior depends on whether the executive-VMCS pointer field contains the VMXON pointer:

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the checks are not performed at all.
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), the checks are performed on the VM-execution control fields in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field in the current VMCS). These checks are performed after checking the executive-VMCS pointer field itself (for proper alignment).

Other VM entries ensure that, if "activate VMX-preemption timer" VM-execution control is 0, the "save VMX-preemption timer value" VM-exit control is also 0. This check is not performed by VM entries that return from SMM.

#### 34.15.4.3 Checks on VM-Entry Control Fields

VM entries that return from SMM differ from other VM entries with regard to the checks performed on the VM-entry control fields specified in Section 26.2.1.3.

Specifically, if the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the following must **not** all hold for the VM-entry interruption-information field:

---

1. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
2. If IA32_VMX_BASIC[48] is read as 1, this pointer must not set any bits in the range 63:32; see Appendix A.1.
3. The STM can determine the VMXON pointer by reading the executive-VMCS pointer field in the current VMCS after the SMM VM exit that activates the dual-monitor treatment.

- the valid bit (bit 31) in the VM-entry interruption-information field is 1
- the interruption type (bits 10:8) is not 7 (other event); and
- the vector (bits 7:0) is not 0 (pending MTF VM exit).

### 34.15.4.4 Checks on the Guest State Area

Section 26.3.1 specifies checks performed on fields in the guest-state area of the VMCS. Some of these checks are conditioned on the settings of certain VM-execution controls (e.g., "virtual NMIs" or "unrestricted guest").
VM entries that return from SMM modify these checks based on whether the executive-VMCS pointer field contains the VMXON pointer:[1]

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the checks are performed as all relevant VM-execution controls were 0. (As a result, some checks may not be performed at all.)
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), this check is performed based on the settings of the VM-execution controls in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field in the current VMCS).

For VM entries that return from SMM, the activity-state field must not indicate the wait-for-SIPI state if the executive-VMCS pointer field contains the VMXON pointer (the VM entry is to VMX root operation).

### 34.15.4.5 Loading Guest State

VM entries that return from SMM load the SMBASE register from the SMBASE field.

VM entries that return from SMM invalidate linear mappings and combined mappings associated with all VPIDs. Combined mappings are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 28.3). (Ordinary VM entries are required to perform such invalidation only for VPID 0000H and are not required to do even that if the "enable VPID" VM-execution control is 1; see Section 26.3.2.5.)

### 34.15.4.6 VMX-Preemption Timer

A VM entry that returns from SMM activates the VMX-preemption timer only if the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation) and the "activate VMX-preemption timer" VM-execution control is 1 in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field). In this case, VM entry starts the VMX-preemption timer with the value in the VMX-preemption timer-value field in the current VMCS.

### 34.15.4.7 Updating the Current-VMCS and SMM-Transfer VMCS Pointers

Successful VM entries (returning from SMM) load the SMM-transfer VMCS pointer with the current-VMCS pointer. Following this, they load the current-VMCS pointer from a field in the current VMCS:

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the current-VMCS pointer is loaded from the VMCS-link pointer field.
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), the current-VMCS pointer is loaded with the value of the executive-VMCS pointer field.

If the VM entry successfully enters VMX non-root operation, the VM-execution controls in effect after the VM entry are those from the new current VMCS. This includes any structures external to the VMCS referenced by VM-execution control fields.

The updating of these VMCS pointers occurs before event injection. Event injection is determined, however, by the VM-entry control fields in the VMCS that was current when the VM entry commenced.

---

1. The STM can determine the VMXON pointer by reading the executive-VMCS pointer field in the current VMCS after the SMM VM exit that activates the dual-monitor treatment.

### 34.15.4.8 VM Exits Induced by VM Entry

Section 26.5.1.2 describes how the event-delivery process invoked by event injection may lead to a VM exit. Section 26.6.3 to Section 26.6.7 describe other situations that may cause a VM exit to occur immediately after a VM entry.

Whether these VM exits occur is determined by the VM-execution control fields in the current VMCS. For VM entries that return from SMM, they can occur only if the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation).

In this case, determination is based on the VM-execution control fields in the VMCS that is current after the VM entry. This is the VMCS referenced by the value of the executive-VMCS pointer field at the time of the VM entry (see Section 34.15.4.7). This VMCS also controls the delivery of such VM exits. Thus, VM exits induced by a VM entry returning from SMM are to the executive monitor and not to the STM.

### 34.15.4.9 SMI Blocking

VM entries that return from SMM determine the blocking of system-management interrupts (SMIs) as follows:

- If the "deactivate dual-monitor treatment" VM-entry control is 0, SMIs are blocked after VM entry if and only if the bit 2 in the interruptibility-state field is 1.
- If the "deactivate dual-monitor treatment" VM-entry control is 1, the blocking of SMIs depends on whether the logical processor is in SMX operation:[1]
  - — If the logical processor is in SMX operation, SMIs are blocked after VM entry.
  - — If the logical processor is outside SMX operation, SMIs are unblocked after VM entry.

VM entries that return from SMM and that do not deactivate the dual-monitor treatment may leave SMIs blocked. This feature exists to allow the STM to invoke functionality outside of SMM without unblocking SMIs.

### 34.15.4.10 Failures of VM Entries That Return from SMM

Section 26.7 describes the treatment of VM entries that fail during or after loading guest state. Such failures record information in the VM-exit information fields and load processor state as would be done on a VM exit. The VMCS used is the one that was current before the VM entry commenced. Control is thus transferred to the STM and the logical processor remains in SMM.

## 34.15.5 Enabling the Dual-Monitor Treatment

Code and data for the SMM-transfer monitor (STM) reside in a region of SMRAM called the **monitor segment** (MSEG). Code running in SMM determines the location of MSEG and establishes its content. This code is also responsible for enabling the dual-monitor treatment.

SMM code enables the dual-monitor treatment and specifies the location of MSEG by writing to the IA32_SMM_MONITOR_CTL MSR (index 9BH). The MSR has the following format:

- Bit 0 is the register's valid bit. The STM may be invoked using VMCALL only if this bit is 1. Because VMCALL is used to activate the dual-monitor treatment (see Section 34.15.6), the dual-monitor treatment cannot be activated if the bit is 0. This bit is cleared when the logical processor is reset.
- Bit 1 is reserved.
- Bit 2 determines whether executions of VMXOFF unblock SMIs under the default treatment of SMIs and SMM. Executions of VMXOFF unblock SMIs unless bit 2 is 1 (the value of bit 0 is irrelevant). See Section 34.14.4.

  Certain leaf functions of the GETSEC instruction clear this bit (see Chapter 5, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2C*)

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.

- Bits 11:3 are reserved.
- Bits 31:12 contain a value that, when shifted right 12 bits, is the physical address of MSEG (the MSEG base address).
- Bits 63:32 are reserved.

The following items detail use of this MSR:

- The IA32_SMM_MONITOR_CTL MSR is supported only on processors that support the dual-monitor treatment.[1] On other processors, accesses to the MSR using RDMSR or WRMSR generate a general-protection fault (#GP(0)).
- A write to the IA32_SMM_MONITOR_CTL MSR using WRMSR generates a general-protection fault (#GP(0)) if executed outside of SMM or if an attempt is made to set any reserved bit. An attempt to write to the IA32_SMM_MONITOR_CTL MSR fails if made as part of a VM exit that does not end in SMM or part of a VM entry that does not begin in SMM.
- Reads from the IA32_SMM_MONITOR_CTL MSR using RDMSR are allowed any time RDMSR is allowed. The MSR may be read as part of any VM exit.
- The dual-monitor treatment can be activated only if the valid bit in the MSR is set to 1.

The 32 bytes located at the MSEG base address are called the **MSEG header**. The format of the MSEG header is given in Table 34-10 (each field is 32 bits).

### Table 34-10. Format of MSEG Header

| Byte Offset | Field |
|---|---|
| 0 | MSEG-header revision identifier |
| 4 | SMM-transfer monitor features |
| 8 | GDTR limit |
| 12 | GDTR base offset |
| 16 | CS selector |
| 20 | EIP offset |
| 24 | ESP offset |
| 28 | CR3 offset |

To ensure proper behavior in VMX operation, software should maintain the MSEG header in writeback cacheable memory. Future implementations may allow or require a different memory type.[2] Software should consult the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1).

SMM code should enable the dual-monitor treatment (by setting the valid bit in IA32_SMM_MONITOR_CTL MSR) only after establishing the content of the MSEG header as follows:

- Bytes 3:0 contain the **MSEG revision identifier**. Different processors may use different MSEG revision identifiers. These identifiers enable software to avoid using an MSEG header formatted for one processor on a processor that uses a different format. Software can discover the MSEG revision identifier that a processor uses by reading the VMX capability MSR IA32_VMX_MISC (see Appendix A.6).

1. Software should consult the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1) to determine whether the dual-monitor treatment is supported.
2. Alternatively, software may map the MSEG header with the UC memory type; this may be necessary, depending on how memory is organized. Doing so is strongly discouraged unless necessary as it will cause the performance of transitions using those structures to suffer significantly. In addition, the processor will continue to use the memory type reported in the VMX capability MSR IA32_VMX_BASIC with exceptions noted in Appendix A.1.

- Bytes 7:4 contain the **SMM-transfer monitor features** field. Bits 31:1 of this field are reserved and must be zero. Bit 0 of the field is the **IA-32e mode SMM feature bit**. It indicates whether the logical processor will be in IA-32e mode after the STM is activated (see Section 34.15.6).
- Bytes 31:8 contain fields that determine how processor state is loaded when the STM is activated (see Section 34.15.6.6). SMM code should establish these fields so that activating of the STM invokes the STM's initialization code.

## 34.15.6 Activating the Dual-Monitor Treatment

The dual-monitor treatment may be enabled by SMM code as described in Section 34.15.5. The dual-monitor treatment is activated only if it is enabled and only by the executive monitor. The executive monitor activates the dual-monitor treatment by executing VMCALL in VMX root operation.

When VMCALL activates the dual-monitor treatment, it causes an SMM VM exit. Differences between this SMM VM exit and other SMM VM exits are discussed in Sections 34.15.6.1 through 34.15.6.7. See also "VMCALL—Call to VM Monitor" in Chapter 30.

### 34.15.6.1 Initial Checks

An execution of VMCALL attempts to activate the dual-monitor treatment if (1) the processor supports the dual-monitor treatment;[1] (2) the logical processor is in VMX root operation; (3) the logical processor is outside SMM and the valid bit is set in the IA32_SMM_MONITOR_CTL MSR; (4) the logical processor is not in virtual-8086 mode and not in compatibility mode; (5) CPL = 0; and (6) the dual-monitor treatment is not active.

The VMCS that manages SMM VM exit caused by this VMCALL is the current VMCS established by the executive monitor. The VMCALL performs the following checks on the current VMCS in the order indicated:

1. There must be a current VMCS pointer.
2. The launch state of the current VMCS must be clear.
3. Reserved bits in the VM-exit controls in the current VMCS must be set properly. Software may consult the VMX capability MSR IA32_VMX_EXIT_CTLS to determine the proper settings (see Appendix A.4).

If any of these checks fail, subsequent checks are skipped and VMCALL fails. If all these checks succeed, the logical processor uses the IA32_SMM_MONITOR_CTL MSR to determine the base address of MSEG. The following checks are performed in the order indicated:

1. The logical processor reads the 32 bits at the base of MSEG and compares them to the processor's MSEG revision identifier.
2. The logical processor reads the SMM-transfer monitor features field:
   - Bit 0 of the field is the IA-32e mode SMM feature bit, and it indicates whether the logical processor will be in IA-32e mode after the SMM-transfer monitor (STM) is activated.
     - If the VMCALL is executed on a processor that does not support Intel 64 architecture, the IA-32e mode SMM feature bit must be 0.
     - If the VMCALL is executed in 64-bit mode, the IA-32e mode SMM feature bit must be 1.
   - Bits 31:1 of this field are currently reserved and must be zero.

If any of these checks fail, subsequent checks are skipped and the VMCALL fails.

### 34.15.6.2 MSEG Checking

SMM VM exits that activate the dual-monitor treatment check the following before updating the current-VMCS pointer and the executive-VMCS pointer field (see Section 34.15.2.2):

1. Software should consult the VMX capability MSR IA32_VMX_BASIC (see Appendix A.1) to determine whether the dual-monitor treatment is supported.

- The 32 bits at the MSEG base address (used as a physical address) must contain the processor's MSEG revision identifier.
- Bits 31:1 of the SMM-transfer monitor features field in the MSEG header (see Table 34-10) must be 0. Bit 0 of the field (the IA-32e mode SMM feature bit) must be 0 if the processor does not support Intel 64 architecture.

If either of these checks fail, execution of VMCALL fails.

### 34.15.6.3 Updating the Current-VMCS and Executive-VMCS Pointers

Before performing the steps in Section 34.15.2.2, SMM VM exits that activate the dual-monitor treatment begin by loading the SMM-transfer VMCS pointer with the value of the current-VMCS pointer.

### 34.15.6.4 Saving Guest State

As noted in Section 34.15.2.4, SMM VM exits save the contents of the SMBASE register into the corresponding field in the guest-state area. While this is true also for SMM VM exits that activate the dual-monitor treatment, the VMCS used for those VM exits exists outside SMRAM.

The SMM-transfer monitor (STM) can also discover the current value of the SMBASE register by using the RDMSR instruction to read the IA32_SMBASE MSR (MSR address 9EH). The following items detail use of this MSR:

- The MSR is supported only if IA32_VMX_MISC[15] = 1 (see Appendix A.6).
- A write to the IA32_SMBASE MSR using WRMSR generates a general-protection fault (#GP(0)). An attempt to write to the IA32_SMBASE MSR fails if made as part of a VM exit or part of a VM entry.
- A read from the IA32_SMBASE MSR using RDMSR generates a general-protection fault (#GP(0)) if executed outside of SMM. An attempt to read from the IA32_SMBASE MSR fails if made as part of a VM exit that does not end in SMM.

### 34.15.6.5 Saving MSRs

The VM-exit MSR-store area is not used by SMM VM exits that activate the dual-monitor treatment. No MSRs are saved into that area.

### 34.15.6.6 Loading Host State

The VMCS that is current during an SMM VM exit that activates the dual-monitor treatment was established by the executive monitor. It does not contain the VM-exit controls and host state required to initialize the STM. For this reason, such SMM VM exits do not load processor state as described in Section 27.5. Instead, state is set to fixed values or loaded based on the content of the MSEG header (see Table 34-10):

- CR0 is set to as follows:
  - PG, NE, ET, MP, and PE are all set to 1.
  - CD and NW are left unchanged.
  - All other bits are cleared to 0.
- CR3 is set as follows:
  - Bits 63:32 are cleared on processors that supports IA-32e mode.
  - Bits 31:12 are set to bits 31:12 of the sum of the MSEG base address and the CR3-offset field in the MSEG header.
  - Bits 11:5 and bits 2:0 are cleared (the corresponding bits in the CR3-offset field in the MSEG header are ignored).
  - Bits 4:3 are set to bits 4:3 of the CR3-offset field in the MSEG header.
- CR4 is set as follows:
  - MCE and PGE are cleared.
  - PAE is set to the value of the IA-32e mode SMM feature bit.

  - If the IA-32e mode SMM feature bit is clear, PSE is set to 1 if supported by the processor; if the bit is set, PSE is cleared.
  - All other bits are unchanged.
- DR7 is set to 400H.
- The IA32_DEBUGCTL MSR is cleared to 00000000_00000000H.
- The registers CS, SS, DS, ES, FS, and GS are loaded as follows:
  - All registers are usable.
  - CS.selector is loaded from the corresponding field in the MSEG header (the high 16 bits are ignored), with bits 2:0 cleared to 0. If the result is 0000H, CS.selector is set to 0008H.
  - The selectors for SS, DS, ES, FS, and GS are set to CS.selector+0008H. If the result is 0000H (if the CS selector was FFF8H), these selectors are instead set to 0008H.
  - The base addresses of all registers are cleared to zero.
  - The segment limits for all registers are set to FFFFFFFFH.
  - The AR bytes for the registers are set as follows:
    - CS.Type is set to 11 (execute/read, accessed, non-conforming code segment).
    - For SS, DS, FS, and GS, the Type is set to 3 (read/write, accessed, expand-up data segment).
    - The S bits for all registers are set to 1.
    - The DPL for each register is set to 0.
    - The P bits for all registers are set to 1.
    - On processors that support Intel 64 architecture, CS.L is loaded with the value of the IA-32e mode SMM feature bit.
    - CS.D is loaded with the inverse of the value of the IA-32e mode SMM feature bit.
    - For each of SS, DS, FS, and GS, the D/B bit is set to 1.
    - The G bits for all registers are set to 1.
- LDTR is unusable. The LDTR selector is cleared to 0000H, and the register is otherwise undefined (although the base address is always canonical)
- GDTR.base is set to the sum of the MSEG base address and the GDTR base-offset field in the MSEG header (bits 63:32 are always cleared on processors that supports IA-32e mode). GDTR.limit is set to the corresponding field in the MSEG header (the high 16 bits are ignored).
- IDTR.base is unchanged. IDTR.limit is cleared to 0000H.
- RIP is set to the sum of the MSEG base address and the value of the RIP-offset field in the MSEG header (bits 63:32 are always cleared on logical processors that support IA-32e mode).
- RSP is set to the sum of the MSEG base address and the value of the RSP-offset field in the MSEG header (bits 63:32 are always cleared on logical processor that supports IA-32e mode).
- RFLAGS is cleared, except bit 1, which is always set.
- The logical processor is left in the active state.
- Event blocking after the SMM VM exit is as follows:
  - There is no blocking by STI or by MOV SS.
  - There is blocking by non-maskable interrupts (NMIs) and by SMIs.
- There are no pending debug exceptions after the SMM VM exit.
- For processors that support IA-32e mode, the IA32_EFER MSR is modified so that LME and LMA both contain the value of the IA-32e mode SMM feature bit.

If any of CR3[63:5], CR4.PAE, CR4.PSE, or IA32_EFER.LMA is changing, the TLBs are updated so that, after VM exit, the logical processor does not use translations that were cached before the transition. This is not neces-

sary for changes that would not affect paging due to the settings of other bits (for example, changes to CR4.PSE if IA32_EFER.LMA was 1 before and after the transition).

### 34.15.6.7 Loading MSRs

The VM-exit MSR-load area is not used by SMM VM exits that activate the dual-monitor treatment. No MSRs are loaded from that area.

## 34.15.7 Deactivating the Dual-Monitor Treatment

The SMM-transfer monitor may deactivate the dual-monitor treatment and return the processor to default treatment of SMIs and SMM (see Section 34.14). It does this by executing a VM entry with the "deactivate dual-monitor treatment" VM-entry control set to 1.

As noted in Section 26.2.1.3 and Section 34.15.4.1, an attempt to deactivate the dual-monitor treatment fails in the following situations: (1) the processor is not in SMM; (2) the "entry to SMM" VM-entry control is 1; or (3) the executive-VMCS pointer does not contain the VMXON pointer (the VM entry is to VMX non-root operation).

As noted in Section 34.15.4.9, VM entries that deactivate the dual-monitor treatment ignore the SMI bit in the interruptibility-state field of the guest-state area. Instead, the blocking of SMIs following such a VM entry depends on whether the logical processor is in SMX operation:[1]

- If the logical processor is in SMX operation, SMIs are blocked after VM entry. SMIs may later be unblocked by the VMXOFF instruction (see Section 34.14.4) or by certain leaf functions of the GETSEC instruction (see Chapter 5, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2C*).
- If the logical processor is outside SMX operation, SMIs are unblocked after VM entry.

# 34.16 SMI AND PROCESSOR EXTENDED STATE MANAGEMENT

On processors that support processor extended states using XSAVE/XRSTOR (see Chapter 13, "Managing State Using the XSAVE Feature Set" of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*), the processor does not save any XSAVE/XRSTOR related state on an SMI. It is the responsibility of the SMI handler code to properly preserve the state information (including CR4.OSXSAVE, XCR0, and possibly processor extended states using XSAVE/XRSTOR). Therefore, the SMI handler must follow the rules described in Chapter 13, "Managing State Using the XSAVE Feature Set" of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*.

# 34.17 MODEL-SPECIFIC SYSTEM MANAGEMENT ENHANCEMENT

This section describes enhancement of system management features that apply only to the 4th generation Intel Core processors. These features are model-specific. BIOS and SMM handler must use CPUID to enumerate DisplayFamily_DisplayModel signature when programming with these interfaces.

## 34.17.1 SMM Handler Code Access Control

The BIOS may choose to restrict the address ranges of code that SMM handler executes. When SMM handler code execution check is enabled, an attempt by the SMM handler to execute outside the ranges specified by SMRR (see Section 34.4.2.1) will cause the assertion of an unrecoverable machine check exception (MCE).

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENTER]. A logical processor is outside SMX operation if GETSEC[SENTER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENTER]. See Chapter 6, "Safer Mode Extensions Reference," in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*.

The interface to enable SMM handler code access check resides in a per-package scope model-specific register MSR_SMM_FEATURE_CONTROL at address 4E0H. An attempt to access MSR_SMM_FEATURE_CONTROL outside of SMM will cause a #GP. Writes to MSR_SMM_FEATURE_CONTROL is further protected by configuration interface of MSR_SMM_MCA_CAP at address 17DH.

Details of the interface of MSR_SMM_FEATURE_CONTROL and MSR_SMM_MCA_CAP are described in Table 35-21.

### 34.17.2 SMI Delivery Delay Reporting

Entry into the system management mode occurs at instruction boundary. In situations where a logical processor is executing an instruction involving a long flow of internal operations, servicing an SMI by that logical processor will be delayed. Delayed servicing of SMI of each logical processor due to executing long flows of internal operation in a physical processor can be queried via a package-scope register MSR_SMM_DELAYED at address 4E2H.

The interface to enable reporting of SMI delivery delay due to long internal flows resides in a per-package scope model-specific register MSR_SMM_DELAYED. An attempt to access MSR_SMM_DELAYED outside of SMM will cause a #GP. Availability to MSR_SMM_DELAYED is protected by configuration interface of MSR_SMM_MCA_CAP at address 17DH.

Details of the interface of MSR_SMM_DELAYED and MSR_SMM_MCA_CAP are described in Table 35-21.

### 34.17.3 Blocked SMI Reporting

A logical processor may have entered into a state and blocked from servicing other interrupts (including SMI). Logical processors in a physical processor that are blocked in serving SMI can be queried in a package-scope register MSR_SMM_BLOCKED at address 4E3H. An attempt to access MSR_SMM_BLOCKED outside of SMM will cause a #GP.

Details of the interface of MSR_SMM_BLOCKED is described in Table 35-21.

# CHAPTER 35
# MODEL-SPECIFIC REGISTERS (MSRS)

This chapter list MSRs across Intel processor families. All MSRs listed can be read with the RDMSR and written with the WRMSR instructions.

Register addresses are given in both hexadecimal and decimal. The register name is the mnemonic register name and the bit description describes individual bits in registers.

Model specific registers and its bit-fields may be supported for a finite range of processor families/models. To distinguish between different processor family and/or models, software must use CPUID.01H leaf function to query the combination of DisplayFamily and DisplayModel to determine model-specific availability of MSRs (see CPUID instruction in Chapter 3, "Instruction Set Reference, A-M" in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*). Table 35-1 lists the signature values of DisplayFamily and DisplayModel for various processor families or processor number series.

**Table 35-1. CPUID Signature Values of DisplayFamily_DisplayModel**

| DisplayFamily_DisplayModel | Processor Families/Processor Number Series |
|---|---|
| **06_4EH** | Future Generation Intel Core Processor |
| **06_56H** | Future Generation Intel Xeon Processor |
| **06_3DH** | Intel Core M-5xxx Processor based on Broadwell microarchitecture |
| **06_3FH** | Intel Xeon processor E5-2600/1600 v3 product families based on Haswell-E microarchitecture, Intel Core i7-59xx Processor Extreme Edition |
| **06_3CH, 06_45H, 06_46H** | 4th Generation Intel Core processor and Intel Xeon processor E3-1200 v3 product family based on Haswell microarchitecture |
| **06_3EH** | Intel Xeon processor E7-8800/4800/2800 v2 product families based on Ivy Bridge-E microarchitecture |
| **06_3EH** | Intel Xeon processor E5-2600/1600 v2 product families and Intel Xeon processor E5-2400 v2 product family based on Ivy Bridge-E microarchitecture, Intel Core i7-49xx Processor Extreme Edition |
| **06_3AH** | 3rd Generation Intel Core Processor and Intel Xeon processor E3-1200 v2 product family based on Ivy Bridge microarchitecture |
| **06_2DH** | Intel Xeon processor E5 Family based on Intel microarchitecture code name Sandy Bridge, Intel Core i7-39xx Processor Extreme Edition |
| **06_2FH** | Intel Xeon Processor E7 Family |
| **06_2AH** | Intel Xeon processor E3-1200 product family; 2nd Generation Intel Core i7, i5, i3 Processors 2xxx Series |
| **06_2EH** | Intel Xeon processor 7500, 6500 series |
| **06_25H, 06_2CH** | Intel Xeon processors 3600, 5600 series, Intel Core i7, i5 and i3 Processors |
| **06_1EH, 06_1FH** | Intel Core i7 and i5 Processors |
| **06_1AH** | Intel Core i7 Processor, Intel Xeon processor 3400, 3500, 5500 series |
| **06_1DH** | Intel Xeon processor MP 7400 series |
| **06_17H** | Intel Xeon processor 3100, 3300, 5200, 5400 series, Intel Core 2 Quad processors 8000, 9000 series |
| **06_0FH** | Intel Xeon processor 3000, 3200, 5100, 5300, 7300 series, Intel Core 2 Quad processor 6000 series, Intel Core 2 Extreme 6000 series, Intel Core 2 Duo 4000, 5000, 6000, 7000 series processors, Intel Pentium dual-core processors |
| **06_0EH** | Intel Core Duo, Intel Core Solo processors |
| **06_0DH** | Intel Pentium M processor |

Table 35-1. CPUID Signature (Contd.)Values of DisplayFamily_DisplayModel (Contd.)

| DisplayFamily_DisplayModel | Processor Families/Processor Number Series |
|---|---|
| **06_4AH, 06_5AH, 06_5DH** | Future Intel Atom Processor Based on Silvermont Microarchitecture |
| **06_37H** | Intel Atom Processor E3000 series, Z3000 series |
| **06_4DH** | Intel Atom Processor C2000 series |
| **06_36H** | Intel Atom Processor S1000 Series |
| **06_1CH, 06_26H, 06_27H, 06_35H, 06_36H** | Intel Atom Processor family, Intel Atom processor D2000, N2000, E2000, Z2000, C1000 series |
| **0F_06H** | Intel Xeon processor 7100, 5000 Series, Intel Xeon Processor MP, Intel Pentium 4, Pentium D processors |
| **0F_03H, 0F_04H** | Intel Xeon Processor, Intel Xeon Processor MP, Intel Pentium 4, Pentium D processors |
| **06_09H** | Intel Pentium M processor |
| **0F_02H** | Intel Xeon Processor, Intel Xeon Processor MP, Intel Pentium 4 processors |
| **0F_0H, 0F_01H** | Intel Xeon Processor, Intel Xeon Processor MP, Intel Pentium 4 processors |
| **06_7H, 06_08H, 06_0AH, 06_0BH** | Intel Pentium III Xeon Processor, Intel Pentium III Processor |
| **06_03H, 06_05H** | Intel Pentium II Xeon Processor, Intel Pentium II Processor |
| **06_01H** | Intel Pentium Pro Processor |
| **05_01H, 05_02H, 05_04H** | Intel Pentium Processor, Intel Pentium Processor with MMX Technology |

## 35.1 ARCHITECTURAL MSRS

Many MSRs have carried over from one generation of IA-32 processors to the next and to Intel 64 processors. A subset of MSRs and associated bit fields, which do not change on future processor generations, are now considered architectural MSRs. For historical reasons (beginning with the Pentium 4 processor), these "architectural MSRs" were given the prefix "IA32_". Table 35-2 lists the architectural MSRs, their addresses, their current names, their names in previous IA-32 processors, and bit fields that are considered architectural. MSR addresses outside Table 35-2 and certain bit fields in an MSR address that may overlap with architectural MSR addresses are model-specific. Code that accesses a machine specified MSR and that is executed on a processor that does not support that MSR will generate an exception.

Architectural MSR or individual bit fields in an architectural MSR may be introduced or transitioned at the granularity of certain processor family/model or the presence of certain CPUID feature flags. The right-most column of Table 35-2 provides information on the introduction of each architectural MSR or its individual fields. This information is expressed either as signature values of "DF_DM" (see Table 35-1) or via CPUID flags.

Certain bit field position may be related to the maximum physical address width, the value of which is expressed as "MAXPHYWID" in Table 35-2. "MAXPHYWID" is reported by CPUID.8000_0008H leaf.

MSR address range between 40000000H - 400000FFH is marked as a specially reserved range. All existing and future processors will not implement any features using any MSR in this range.

Table 35-2. IA-32 Architectural MSRs

| Register Address | | Architectural MSR Name and bit fields (Former MSR Name) | MSR/Bit Description | Comment |
|---|---|---|---|---|
| Hex | Decimal | | | |
| 0H | 0 | IA32_P5_MC_ADDR (P5_MC_ADDR) | See Section 35.19, "MSRs in Pentium Processors." | **Pentium Processor (05_01H)** |
| 1H | 1 | IA32_P5_MC_TYPE (P5_MC_TYPE) | See Section 35.19, "MSRs in Pentium Processors." | DF_DM = 05_01H |

## Table 35-2. IA-32 Architectural MSRs (Contd.)

| Register Address | | Architectural MSR Name and bit fields (Former MSR Name) | MSR/Bit Description | Comment |

## Table 35-2. IA-32 Architectural MSRs (Contd.)

| Register Address | | Architectural MSR Name and bit fields (Former MSR Name) | MSR/Bit Description | Comment |
|---|---|---|---|---|
| Hex | Decimal | | | |
| 4000_0000H - 4000_00FFH | | Reserved MSR Address Space | **All existing and future processors will not implement MSR in this range.** | |
| C000_0080H | | IA32_EFER | **Extended Feature Enables** | If ( CPUID.80000001.EDX.[bit 20] or CPUID.80000001.EDX.[bit 29]) |
| | | 0 | **SYSCALL Enable: IA32_EFER.SCE (R/W)** Enables SYSCALL/SYSRET instructions in 64-bit mode. | |
| | | 7:1 | Reserved. | |
| | | 8 | **IA-32e Mode Enable: IA32_EFER.LME (R/W)** Enables IA-32e mode operation. | |
| | | 9 | Reserved. | |
| | | 10 | **IA-32e Mode Active: IA32_EFER.LMA (R)** Indicates IA-32e mode is active when set. | |
| | | 11 | **Execute Disable Bit Enable: IA32_EFER.NXE (R/W)** | |
| | | 63:12 | Reserved. | |
| C000_0081H | | IA32_STAR | **System Call Target Address (R/W)** | If CPUID.80000001.EDX.[bit 29] = 1 |
| C000_0082H | | IA32_LSTAR | **IA-32e Mode System Call Target Address (R/W)** | If CPUID.80000001.EDX.[bit 29] = 1 |
| C000_0084H | | IA32_FMASK | **System Call Flag Mask (R/W)** | If CPUID.80000001.EDX.[bit 29] = 1 |
| C000_0100H | | IA32_FS_BASE | **Map of BASE Address of FS (R/W)** | If CPUID.80000001.EDX.[bit 29] = 1 |
| C000_0101H | | IA32_GS_BASE | **Map of BASE Address of GS (R/W)** | If CPUID.80000001.EDX.[bit 29] = 1 |
| C000_0102H | | IA32_KERNEL_GS_BASE | **Swap Target of BASE Address of GS (R/W)** | If CPUID.80000001.EDX.[bit 29] = 1 |
| C000_0103H | | IA32_TSC_AUX | Auxiliary TSC (RW) | If CPUID.80000001H: EDX[27] = 1 |
| | | 31:0 | AUX: Auxiliary signature of TSC | |
| | | 63:32 | Reserved. | |

**NOTES:**

1. In processors based on Intel NetBurst® microarchitecture, MSR addresses 180H-197H are supported, software must treat them as model-specific. Starting with Intel Core Duo processors, MSR addresses 180H-185H, 188H-197H are reserved.
2. The *_ADDR MSRs may or may not be present; this depends on flag settings in IA32_MC*i*_STATUS. See Section 15.3.2.3 and Section 15.3.2.4 for more information.
3. MAXPHYADDR is reported by CPUID.80000008H:EAX[7:0].

## 35.2 MSRS IN THE INTEL® CORE™ 2 PROCESSOR FAMILY

Table 35-3 lists model-specific registers (MSRs) for Intel Core 2 processor family and for Intel Xeon processors based on Intel Core microarchitecture, architectural MSR addresses are also included in Table 35-3. These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_0FH, see Table 35-1.

MSRs listed in Table 35-2 and Table 35-3 are also supported by processors based on the Enhanced Intel Core microarchitecture. Processors based on the Enhanced Intel Core microarchitecture have the CPUID signature DisplayFamily_DisplayModel of 06_17H.

The column "Shared/Unique" applies to multi-core processors based on Intel Core microarchitecture. "Unique" means each processor core has a separate MSR, or a bit field in an MSR governs only a core independently. "Shared" means the MSR or the bit field in an MSR address governs the operation of both processor cores.

**Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture**

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 0H | 0 | IA32_P5_MC_ADDR | Unique | See Section 35.19, "MSRs in Pentium Processors." |
| 1H | 1 | IA32_P5_MC_TYPE | Unique | See Section 35.19, "MSRs in Pentium Processors." |
| 6H | 6 | IA32_MONITOR_FILTER_SIZE | Unique | See Section 8.10.5, "Monitor/Mwait Address Range Determination." andTable 35-2. |
| 10H | 16 | IA32_TIME_STAMP_COUNTER | Unique | See Section 17.13, "Time-Stamp Counter," and see Table 35-2. |

| | | 10 | Shared | **FERR# Multiplexing Enable (R/W)**<br>1 = FERR# asserted by the processor to indicate a pending break event within the processor<br>0 = Indicates compatible FERR# signaling behavior<br>This bit must be set to 1 to support XAPIC interrupt model usage. |
| | | 11 | Shared | **Branch Trace Storage Unavailable (RO)**<br>See Table 35-2. |
| | | 12 | Shared | **Precise Event Based Sampling Unavailable (RO)**<br>See Table 35-2. |

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| | | 13 | Shared | **TM2 Enable (R/W)**<br>When this bit is set (1) and the thermal sensor indicates that the die temperature is at the pre-determined threshold, the Thermal Monitor 2 mechanism is engaged. TM2 will reduce the bus to core ratio and voltage according to the value last written to MSR_THERM2_CTL bits 15:0. |
| | | | | When this bit is clear (0, default), the processor does not change the VID signals or the bus to core ratio when the processor enters a thermally managed state.<br>The BIOS must enable this feature if the TM2 feature flag (CPUID.1:ECX[8]) is set; if the TM2 feature flag is not set, this feature is not supported and BIOS must not alter the contents of the TM2 bit location.<br>The processor is operating out of specification if both this bit and the TM1 bit are set to 0. |
| | | 15:14 | | Reserved. |
| | | 16 | Shared | **Enhanced Intel SpeedStep Technology Enable (R/W)**<br>See Table 35-2. |
| | | 18 | Shared | **ENABLE MONITOR FSM (R/W)**<br>See Table 35-2. |
| | | 19 | Shared | **Adjacent Cache Line Prefetch Disable (R/W)**<br>When set to 1, the processor fetches the cache line that contains data currently required by the processor. When set to 0, the processor fetches cache lines that comprise a cache line pair (128 bytes).<br>Single processor platforms should not set this bit. Server platforms should set or clear this bit based on platform performance observed in validation and testing.<br>BIOS may contain a setup option that controls the setting of this bit. |
| | | 20 | Shared | **Enhanced Intel SpeedStep Technology Select Lock (R/WO)**<br>When set, this bit causes the following bits to become read-only:<br>▪ Enhanced Intel SpeedStep Technology Select Lock (this bit),<br>▪ Enhanced Intel SpeedStep Technology Enable bit.<br><br>The bit must be set before an Enhanced Intel SpeedStep Technology transition is requested. This bit is cleared on reset. |
| | | 21 | | Reserved. |
| | | 22 | Shared | **Limit CPUID Maxval (R/W)**<br>See Table 35-2. |
| | | 23 | Shared | **xTPR Message Disable (R/W)**<br>See Table 35-2. |
| | | 33:24 | | Reserved. |

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| | | 34 | Unique | **XD Bit Disable (R/W)**<br>See Table 35-2. |
| | | 36:35 | | Reserved. |
| | | 37 | Unique | **DCU Prefetcher Disable (R/W)**<br>When set to 1, The DCU L1 data cache prefetcher is disabled. The default value after reset is 0. BIOS may write '1' to disable this feature.<br>The DCU prefetcher is an L1 data cache prefetcher. When the DCU prefetcher detects multiple loads from the same line done within a time limit, the DCU prefetcher assumes the next line will be required. The next line is prefetched in to the L1 data cache from memory or L2. |
| | | 38 | Shared | **IDA Disable (R/W)**<br>When set to 1 on processors that support IDA, the Intel Dynamic Acceleration feature (IDA) is disabled and the IDA_Enable feature flag will be clear (CPUID.06H: EAX[1]=0).<br>When set to a 0 on processors that support IDA, CPUID.06H: EAX[1] reports the processor's support of IDA is enabled.<br>**Note:** the power-on default value is used by BIOS to detect hardware support of IDA. If power-on default value is 1, IDA is available in the processor. If power-on default value is 0, IDA is not available. |
| | | 39 | Unique | **IP Prefetcher Disable (R/W)**<br>When set to 1, The IP prefetcher is disabled. The default value after reset is 0. BIOS may write '1' to disable this feature.<br>The IP prefetcher is an L1 data cache prefetcher. The IP prefetcher looks for sequential load history to determine whether to prefetch the next expected data into the L1 cache from memory or L2. |
| | | 63:40 | | Reserved. |

| 1DEH | 478 | MSR_LER_TO_LIP | Unique | **Last Exception Record To Linear IP (R)**<br>This area contains a pointer to the target of the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled. |

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 200H | 512 | IA32_MTRR_PHYSBASE0 | Unique | See Table 35-2. |
| 201H | 513 | IA32_MTRR_PHYSMASK0 | Unique | See Table 35-2. |
| 202H | 514 | IA32_MTRR_PHYSBASE1 | Unique | See Table 35-2. |
| 203H | 515 | IA32_MTRR_PHYSMASK1 | Unique | See Table 35-2. |
| 204H | 516 | IA32_MTRR_PHYSBASE2 | Unique | See Table 35-2. |
| 205H | 517 | IA32_MTRR_PHYSMASK2 | Unique | See Table 35-2. |
| 206H | 518 | IA32_MTRR_PHYSBASE3 | Unique | See Table 35-2. |
| 207H | 519 | IA32_MTRR_PHYSMASK3 | Unique | See Table 35-2. |
| 208H | 520 | IA32_MTRR_PHYSBASE4 | Unique | See Table 35-2. |
| 209H | 521 | IA32_MTRR_PHYSMASK4 | Unique | See Table 35-2. |
| 20AH | 522 | IA32_MTRR_PHYSBASE5 | Unique | See Table 35-2. |
| 20BH | 523 | IA32_MTRR_PHYSMASK5 | Unique | See Table 35-2. |
| 20CH | 524 | IA32_MTRR_PHYSBASE6 | Unique | See Table 35-2. |
| 20DH | 525 | IA32_MTRR_PHYSMASK6 | Unique | See Table 35-2. |
| 20EH | 526 | IA32_MTRR_PHYSBASE7 | Unique | See Table 35-2. |
| 20FH | 527 | IA32_MTRR_PHYSMASK7 | Unique | See Table 35-2. |
| 250H | 592 | IA32_MTRR_FIX64K_ 00000 | Unique | See Table 35-2. |
| 258H | 600 | IA32_MTRR_FIX16K_ 80000 | Unique | See Table 35-2. |
| 259H | 601 | IA32_MTRR_FIX16K_ A0000 | Unique | See Table 35-2. |
| 268H | 616 | IA32_MTRR_FIX4K_C0000 | Unique | See Table 35-2. |
| 269H | 617 | IA32_MTRR_FIX4K_C8000 | Unique | See Table 35-2. |
| 26AH | 618 | IA32_MTRR_FIX4K_D0000 | Unique | See Table 35-2. |
| 26BH | 619 | IA32_MTRR_FIX4K_D8000 | Unique | See Table 35-2. |
| 26CH | 620 | IA32_MTRR_FIX4K_E0000 | Unique | See Table 35-2. |
| 26DH | 621 | IA32_MTRR_FIX4K_E8000 | Unique | See Table 35-2. |
| 26EH | 622 | IA32_MTRR_FIX4K_F0000 | Unique | See Table 35-2. |
| 26FH | 623 | IA32_MTRR_FIX4K_F8000 | Unique | See Table 35-2. |
| 277H | 631 | IA32_PAT | Unique | See Table 35-2. |
| 2FFH | 767 | IA32_MTRR_DEF_TYPE | Unique | **Default Memory Types (R/W)** See Table 35-2. |
| 309H | 777 | IA32_FIXED_CTR0 | Unique | **Fixed-Function Performance Counter Register 0 (R/W)** See Table 35-2. |
| 309H | 777 | MSR_PERF_FIXED_CTR0 | Unique | **Fixed-Function Performance Counter Register 0 (R/W)** |

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 30AH | 778 | IA32_FIXED_CTR1 | Unique | **Fixed-Function Performance Counter Register 1 (R/W)**<br>See Table 35-2. |
| 30AH | 778 | MSR_PERF_FIXED_CTR1 | Unique | **Fixed-Function Performance Counter Register 1 (R/W)** |
| 30BH | 779 | IA32_FIXED_CTR2 | Unique | **Fixed-Function Performance Counter Register 2 (R/W)**<br>See Table 35-2. |
| 30BH | 779 | MSR_PERF_FIXED_CTR2 | Unique | **Fixed-Function Performance Counter Register 2 (R/W)** |
| 345H | 837 | IA32_PERF_CAPABILITIES | Unique | See Table 35-2. See Section 17.4.1, "IA32_DEBUGCTL MSR." |
| 345H | 837 | MSR_PERF_CAPABILITIES | Unique | RO. This applies to processors that do not support architectural perfmon version 2. |
| | | 5:0 | | LBR Format. See Table 35-2. |
| | | 6 | | PEBS Record Format. |
| | | 7 | | PEBSSaveArchRegs. See Table 35-2. |
| | | 63:8 | | Reserved. |
| 38DH | 909 | IA32_FIXED_CTR_CTRL | Unique | **Fixed-Function-Counter Control Register (R/W)**<br>See Table 35-2. |
| 38DH | 909 | MSR_PERF_FIXED_CTR_ CTRL | Unique | **Fixed-Function-Counter Control Register (R/W)** |
| 38EH | 910 | IA32_PERF_GLOBAL_ STAUS | Unique | See Table 35-2. See Section 18.4.2, "Global Counter Control Facilities." |
| 38EH | 910 | MSR_PERF_GLOBAL_STAUS | Unique | See Section 18.4.2, "Global Counter Control Facilities." |
| 38FH | 911 | IA32_PERF_GLOBAL_CTRL | Unique | See Table 35-2. See Section 18.4.2, "Global Counter Control Facilities." |
| 38FH | 911 | MSR_PERF_GLOBAL_CTRL | Unique | See Section 18.4.2, "Global Counter Control Facilities." |
| 390H | 912 | IA32_PERF_GLOBAL_OVF_ CTRL | Unique | See Table 35-2. See Section 18.4.2, "Global Counter Control Facilities." |
| 390H | 912 | MSR_PERF_GLOBAL_OVF_ CTRL | Unique | See Section 18.4.2, "Global Counter Control Facilities." |
| 3F1H | 1009 | MSR_PEBS_ENABLE | Unique | See Table 35-2. See Section 18.4.4, "Precise Event Based Sampling (PEBS)." |
| | | 0 | | Enable PEBS on IA32_PMC0. (R/W) |
| 400H | 1024 | IA32_MC0_CTL | Unique | See Section 15.3.2.1, "IA32_MCi_CTL MSRs." |
| 401H | 1025 | IA32_MC0_STATUS | Unique | See Section 15.3.2.2, "IA32_MCi_STATUS MSRS." |
| 402H | 1026 | IA32_MC0_ADDR | Unique | See Section 15.3.2.3, "IA32_MCi_ADDR MSRs."<br>The IA32_MC0_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC0_STATUS register is clear.<br>When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception. |
| 404H | 1028 | IA32_MC1_CTL | Unique | See Section 15.3.2.1, "IA32_MCi_CTL MSRs." |

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 405H | 1029 | IA32_MC1_STATUS | Unique | See Section 15.3.2.2, "IA32_MCi_STATUS MSRS." |
| 406H | 1030 | IA32_MC1_ADDR | Unique | See Section 15.3.2.3, "IA32_MCi_ADDR MSRs."<br>The IA32_MC1_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC1_STATUS register is clear.<br>When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception. |
| 408H | 1032 | IA32_MC2_CTL | Unique | See Section 15.3.2.1, "IA32_MCi_CTL MSRs." |
| 409H | 1033 | IA32_MC2_STATUS | Unique | See Section 15.3.2.2, "IA32_MCi_STATUS MSRS." |
| 40AH | 1034 | IA32_MC2_ADDR | Unique | See Section 15.3.2.3, "IA32_MCi_ADDR MSRs."<br>The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC2_STATUS register is clear.<br>When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception. |
| 40CH | 1036 | MSR_MC4_CTL | Unique | See Section 15.3.2.1, "IA32_MCi_CTL MSRs." |
| 40DH | 1037 | MSR_MC4_STATUS | Unique | See Section 15.3.2.2, "IA32_MCi_STATUS MSRS." |
| 40EH | 1038 | MSR_MC4_ADDR | Unique | See Section 15.3.2.3, "IA32_MCi_ADDR MSRs."<br>The MSR_MC4_ADDR register is either not implemented or contains no address if the ADDRV flag in the MSR_MC4_STATUS register is clear.<br>When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception. |
| 410H | 1040 | MSR_MC3_CTL | | See Section 15.3.2.1, "IA32_MCi_CTL MSRs." |
| 411H | 1041 | MSR_MC3_STATUS | | See Section 15.3.2.2, "IA32_MCi_STATUS MSRS." |
| 412H | 1042 | MSR_MC3_ADDR | Unique | See Section 15.3.2.3, "IA32_MCi_ADDR MSRs."<br>The MSR_MC3_ADDR register is either not implemented or contains no address if the ADDRV flag in the MSR_MC3_STATUS register is clear.<br>When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception. |
| 413H | 1043 | MSR_MC3_MISC | Unique | |
| 414H | 1044 | MSR_MC5_CTL | Unique | |
| 415H | 1045 | MSR_MC5_STATUS | Unique | |
| 416H | 1046 | MSR_MC5_ADDR | Unique | |
| 417H | 1047 | MSR_MC5_MISC | Unique | |
| 419H | 1045 | MSR_MC6_STATUS | Unique | Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 15.3.2.2, "IA32_MCi_STATUS MSRS." and Chapter 23. |

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 480H | 1152 | IA32_VMX_BASIC | Unique | **Reporting Register of Basic VMX Capabilities (R/O)**<br>See Table 35-2.<br>See Appendix A.1, "Basic VMX Information." |
| 481H | 1153 | IA32_VMX_PINBASED_ CTLS | Unique | **Capability Reporting Register of Pin-based VM-execution Controls (R/O)**<br>See Table 35-2.<br>See Appendix A.3, "VM-Execution Controls." |
| 482H | 1154 | IA32_VMX_PROCBASED_ CTLS | Unique | **Capability Reporting Register of Primary Processor-based VM-execution Controls (R/O)**<br>See Appendix A.3, "VM-Execution Controls." |
| 483H | 1155 | IA32_VMX_EXIT_CTLS | Unique | **Capability Reporting Register of VM-exit Controls (R/O)**<br>See Table 35-2.<br>See Appendix A.4, "VM-Exit Controls." |
| 484H | 1156 | IA32_VMX_ENTRY_CTLS | Unique | **Capability Reporting Register of VM-entry Controls (R/O)**<br>See Table 35-2.<br>See Appendix A.5, "VM-Entry Controls." |
| 485H | 1157 | IA32_VMX_MISC | Unique | **Reporting Register of Miscellaneous VMX Capabilities (R/O)**<br>See Table 35-2.<br>See Appendix A.6, "Miscellaneous Data." |
| 486H | 1158 | IA32_VMX_CR0_FIXED0 | Unique | **Capability Reporting Register of CR0 Bits Fixed to 0 (R/O)**<br>See Table 35-2.<br>See Appendix A.7, "VMX-Fixed Bits in CR0." |
| 487H | 1159 | IA32_VMX_CR0_FIXED1 | Unique | **Capability Reporting Register of CR0 Bits Fixed to 1 (R/O)**<br>See Table 35-2.<br>See Appendix A.7, "VMX-Fixed Bits in CR0." |
| 488H | 1160 | IA32_VMX_CR4_FIXED0 | Unique | **Capability Reporting Register of CR4 Bits Fixed to 0 (R/O)**<br>See Table 35-2.<br>See Appendix A.8, "VMX-Fixed Bits in CR4." |
| 489H | 1161 | IA32_VMX_CR4_FIXED1 | Unique | **Capability Reporting Register of CR4 Bits Fixed to 1 (R/O)**<br>See Table 35-2.<br>See Appendix A.8, "VMX-Fixed Bits in CR4." |
| 48AH | 1162 | IA32_VMX_VMCS_ENUM | Unique | **Capability Reporting Register of VMCS Field Enumeration (R/O)**<br>See Table 35-2.<br>See Appendix A.9, "VMCS Enumeration." |
| 48BH | 1163 | IA32_VMX_PROCBASED_ CTLS2 | Unique | **Capability Reporting Register of Secondary Processor-based VM-execution Controls (R/O)**<br>See Appendix A.3, "VM-Execution Controls." |

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 600H | 1536 | IA32_DS_AREA | Unique | **DS Save Area (R/W)**<br>See Table 35-2.<br>See Section 18.13.4, "Debug Store (DS) Mechanism." |
| 107CC H | | MSR_EMON_L3_CTR_CTL0 | Unique | **GBUSQ Event Control/Counter Register (R/W)**<br>Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2 |
| 107CD H | | MSR_EMON_L3_CTR_CTL1 | Unique | **GBUSQ Event Control/Counter Register (R/W)**<br>Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2 |
| 107CE H | | MSR_EMON_L3_CTR_CTL2 | Unique | **GSNPQ Event Control/Counter Register (R/W)**<br>Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2 |
| 107CF H | | MSR_EMON_L3_CTR_CTL3 | Unique | **GSNPQ Event Control/Counter Register (R/W)**<br>Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2 |
| 107D0 H | | MSR_EMON_L3_CTR_CTL4 | Unique | **FSB Event Control/Counter Register (R/W)**<br>Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2 |
| 107D1 H | | MSR_EMON_L3_CTR_CTL5 | Unique | **FSB Event Control/Counter Register (R/W)**<br>Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2 |
| 107D2 H | | MSR_EMON_L3_CTR_CTL6 | Unique | **FSB Event Control/Counter Register (R/W)**<br>Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2 |
| 107D3 H | | MSR_EMON_L3_CTR_CTL7 | Unique | **FSB Event Control/Counter Register (R/W)**<br>Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2 |
| 107D8 H | | MSR_EMON_L3_GL_CTL | Unique | **L3/FSB Common Control Register (R/W)**<br>Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2 |
| C000_ 0080H | | IA32_EFER | Unique | **Extended Feature Enables**<br>See Table 35-2. |
| C000_ 0081H | | IA32_STAR | Unique | **System Call Target Address (R/W)**<br>See Table 35-2. |
| C000_ 0082H | | IA32_LSTAR | Unique | **IA-32e Mode System Call Target Address (R/W)**<br>See Table 35-2. |
| C000_ 0084H | | IA32_FMASK | Unique | **System Call Flag Mask (R/W)**<br>See Table 35-2. |
| C000_ 0100H | | IA32_FS_BASE | Unique | **Map of BASE Address of FS (R/W)**<br>See Table 35-2. |

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| C000_ 0101H | | IA32_GS_BASE | Unique | **Map of BASE Address of GS (R/W)** See Table 35-2. |
| C000_ 0102H | | IA32_KERNEL_GSBASE | Unique | **Swap Target of BASE Address of GS (R/W)** See Table 35-2. |

## 35.3 MSRS IN THE INTEL® ATOM™ PROCESSOR FAMILY

Table 35-4 lists model-specific registers (MSRs) for Intel Atom processor family, architectural MSR addresses are also included in Table 35-4. These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_1CH, 06_26H, 06_27H, 06_35H and 06_36H, see Table 35-1.

The column "Shared/Unique" applies to logical processors sharing the same core in processors based on the Intel Atom microarchitecture. "Unique" means each logical processor has a separate MSR, or a bit field in an MSR governs only a logical processor. "Shared" means the MSR or the bit field in an MSR address governs the operation of both logical processors in the same core.

Table 35-4. MSRs in Intel® Atom™ Processor Family

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 0H | 0 | IA32_P5_MC_ADDR | Shared | See Section 35.19, "MSRs in Pentium Processors." |
| 1H | 1 | IA32_P5_MC_TYPE | Shared | See Section 35.19, "MSRs in Pentium Processors." |
| 6H | 6 | IA32_MONITOR_FILTER_ SIZE | Unique | See Section 8.10.5, "Monitor/Mwait Address Range Determination." andTable 35-2 |
| 10H | 16 | IA32_TIME_STAMP_ COUNTER | Unique | See Section 17.13, "Time-Stamp Counter," and see Table 35-2. |
| 17H | 23 | IA32_PLATFORM_ID | Shared | **Platform ID (R)** See Table 35-2. |
| 17H | 23 | MSR_PLATFORM_ID | Shared | **Model Specific Platform ID (R)** |
| | | 7:0 | | Reserved. |
| | | 12:8 | | **Maximum Qualified Ratio (R)** The maximum allowed bus ratio. |
| | | 63:13 | | Reserved. |
| 1BH | 27 | IA32_APIC_BASE | Unique | See Section 10.4.4, "Local APIC Status and Location," and Table 35-2. |
| 2AH | 42 | MSR_EBL_CR_POWERON | Shared | **Processor Hard Power-On Configuration (R/W)** Enables and disables processor features; **(R)** indicates current processor configuration. |
| | | 0 | | Reserved. |

Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| | | 1 | | **Data Error Checking Enable (R/W)**<br>1 = Enabled; 0 = Disabled<br>Always 0. |
| | | 2 | | **Response Error Checking Enable (R/W)**<br>1 = Enabled; 0 = Disabled<br>Always 0. |
| | | 3 | | **AERR# Drive Enable (R/W)**<br>1 = Enabled; 0 = Disabled<br>Always 0. |
| | | 4 | | **BERR# Enable for initiator bus requests (R/W)**<br>1 = Enabled; 0 = Disabled<br>Always 0. |
| | | 5 | | Reserved. |
| | | 6 | | Reserved. |
| | | 7 | | **BINIT# Driver Enable (R/W)**<br>1 = Enabled; 0 = Disabled<br>Always 0. |
| | | 8 | | Reserved. |
| | | 9 | | **Execute BIST (R/O)**<br>1 = Enabled; 0 = Disabled |
| | | 10 | | **AERR# Observation Enabled (R/O)**<br>1 = Enabled; 0 = Disabled<br>Always 0. |
| | | 11 | | Reserved. |
| | | 12 | | **BINIT# Observation Enabled (R/O)**<br>1 = Enabled; 0 = Disabled<br>Always 0. |
| | | 13 | | **Reserved.** |
| | | 14 | | **1 MByte Power on Reset Vector (R/O)**<br>1 = 1 MByte; 0 = 4 GBytes |
| | | 15 | | Reserved |
| | | 17:16 | | **APIC Cluster ID (R/O)**<br>Always 00B. |
| | | 19: 18 | | Reserved. |
| | | 21: 20 | | **Symmetric Arbitration ID (R/O)**<br>Always 00B. |
| | | 26:22 | | **Integer Bus Frequency Ratio (R/O)** |
| 3AH | 58 | IA32_FEATURE_CONTROL | Unique | **Control Features in Intel 64Processor (R/W)**<br>See Table 35-2. |

Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 40H | 64 | MSR_ LASTBRANCH_0_FROM_IP | Unique | **Last Branch Record 0 From IP (R/W)**<br>One of eight pairs of last branch record registers on the last branch record stack. This part of the stack contains pointers to the **source instruction** for one of the last eight branches, exceptions, or interrupts taken by the processor. See also:<br>▪ Last Branch Record Stack TOS at 1C9H<br>▪ Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)." |
| 41H | 65 | MSR_ LASTBRANCH_1_FROM_IP | Unique | **Last Branch Record 1 From IP (R/W)**<br>See description of MSR_LASTBRANCH_0_FROM_IP. |
| 42H | 66 | MSR_ LASTBRANCH_2_FROM_IP | Unique | **Last Branch Record 2 From IP (R/W)**<br>See description of MSR_LASTBRANCH_0_FROM_IP. |
| 43H | 67 | MSR_ LASTBRANCH_3_FROM_IP | Unique | **Last Branch Record 3 From IP (R/W)**<br>See description of MSR_LASTBRANCH_0_FROM_IP. |
| 44H | 68 | MSR_ LASTBRANCH_4_FROM_IP | Unique | **Last Branch Record 4 From IP (R/W)**<br>See description of MSR_LASTBRANCH_0_FROM_IP. |
| 45H | 69 | MSR_ LASTBRANCH_5_FROM_IP | Unique | **Last Branch Record 5 From IP (R/W)**<br>See description of MSR_LASTBRANCH_0_FROM_IP. |
| 46H | 70 | MSR_ LASTBRANCH_6_FROM_IP | Unique | **Last Branch Record 6 From IP (R/W)**<br>See description of MSR_LASTBRANCH_0_FROM_IP. |
| 47H | 71 | MSR_ LASTBRANCH_7_FROM_IP | Unique | **Last Branch Record 7 From IP (R/W)**<br>See description of MSR_LASTBRANCH_0_FROM_IP. |
| 60H | 96 | MSR_ LASTBRANCH_0_TO_IP | Unique | **Last Branch Record 0 To IP (R/W)**<br>One of eight pairs of last branch record registers on the last branch record stack. This part of the stack contains pointers to the destination instruction for one of the last eight branches, exceptions, or interrupts taken by the processor. |
| 61H | 97 | MSR_ LASTBRANCH_1_TO_IP | Unique | **Last Branch Record 1 To IP (R/W)**<br>See description of MSR_LASTBRANCH_0_TO_IP. |
| 62H | 98 | MSR_ LASTBRANCH_2_TO_IP | Unique | **Last Branch Record 2 To IP (R/W)**<br>See description of MSR_LASTBRANCH_0_TO_IP. |
| 63H | 99 | MSR_ LASTBRANCH_3_TO_IP | Unique | **Last Branch Record 3 To IP (R/W)**<br>See description of MSR_LASTBRANCH_0_TO_IP. |
| 64H | 100 | MSR_ LASTBRANCH_4_TO_IP | Unique | **Last Branch Record 4 To IP (R/W)**<br>See description of MSR_LASTBRANCH_0_TO_IP. |
| 65H | 101 | MSR_ LASTBRANCH_5_TO_IP | Unique | **Last Branch Record 5 To IP (R/W)**<br>See description of MSR_LASTBRANCH_0_TO_IP. |
| 66H | 102 | MSR_ LASTBRANCH_6_TO_IP | Unique | **Last Branch Record 6 To IP (R/W)**<br>See description of MSR_LASTBRANCH_0_TO_IP. |
| 67H | 103 | MSR_ LASTBRANCH_7_TO_IP | Unique | **Last Branch Record 7 To IP (R/W)**<br>See description of MSR_LASTBRANCH_0_TO_IP. |

Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 79H | 121 | IA32_BIOS_UPDT_TRIG | Shared | **BIOS Update Trigger Register (W)**<br>See Table 35-2. |
| 8BH | 139 | IA32_BIOS_SIGN_ID | Unique | **BIOS Update Signature ID (RO)**<br>See Table 35-2. |
| C1H | 193 | IA32_PMC0 | Unique | **Performance counter register**<br>See Table 35-2. |
| C2H | 194 | IA32_PMC1 | Unique | **Performance Counter Register**<br>See Table 35-2. |
| CDH | 205 | MSR_FSB_FREQ | Shared | **Scaleable Bus Speed(RO)**<br>This field indicates the intended scaleable bus clock speed for processors based on Intel Atom microarchitecture: |
| | | 2:0 | | ▪ 111B: 083 MHz (FSB 333)<br>▪ 101B: 100 MHz (FSB 400)<br>▪ 001B: 133 MHz (FSB 533)<br>▪ 011B: 167 MHz (FSB 667)<br>133.33 MHz should be utilized if performing calculation with System Bus Speed when encoding is 001B.<br>166.67 MHz should be utilized if performing calculation with System Bus Speed when encoding is 011B. |

Table 35-5 lists model-specific registers (MSRs) that are specific to Intel® Atom™ processor with the CPUID signature with DisplayFamily_DisplayModel of 06_27H.

**Table 35-5. MSRs Supported by Intel® Atom™ Processors with CPUID Signature 06_27H**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 3F8H | 1016 | MSR_PKG_C2_RESIDENCY | Package | **Package C2 Residency**<br>Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States |
| | | 63:0 | Package | Package C2 Residency Counter. (R/O)<br>Time that this package is in processor-specific C2 states since last reset. Counts at 1 Mhz frequency. |
| 3F9H | 1017 | MSR_PKG_C4_RESIDENCY | Package | **Package C4 Residency**<br>Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States |
| | | 63:0 | Package | Package C4 Residency Counter. (R/O)<br>Time that this package is in processor-specific C4 states since last reset. Counts at 1 Mhz frequency. |
| 3FAH | 1018 | MSR_PKG_C6_RESIDENCY | Package | **Package C6 Residency**<br>Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States |
| | | 63:0 | Package | Package C6 Residency Counter. (R/O)<br>Time that this package is in processor-specific C6 states since last reset. Counts at 1 Mhz frequency. |

## 35.4 MSRS IN THE PROCESSORS BASED ON SILVERMONT MICROARCHITECTURE

Table 35-6 lists model-specific registers (MSRs) for Intel processors based on the Silvermont microarchitecture These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_37H, 06_4AH, 06_4DH, 06_5AH, and 06_5DH, see Table 35-1.

The column "Scope" lists the core/shared/package granularity of sharing in the Silvermont microarchitecture. "Core" means each processor core has a separate MSR, or a bit field not shared with another processor core. "Shared" means the MSR or the bit field is shared by more than one processor cores in the physical package. "Package" means all processor cores in the physical package share the same MSR or bit interface.

**Table 35-6. Common MSRs in Intel Processors Based on the Silvermont Microarchitecture**

| Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 0H | 0 | IA32_P5_MC_ADDR | Shared | See Section 35.19, "MSRs in Pentium Processors." |
| 1H | 1 | IA32_P5_MC_TYPE | Shared | See Section 35.19, "MSRs in Pentium Processors." |
| 6H | 6 | IA32_MONITOR_FILTER_SIZE | Core | See Section 8.10.5, "Monitor/Mwait Address Range Determination." andTable 35-2 |
| 10H | 16 | IA32_TIME_STAMP_COUNTER | Core | See Section 17.13, "Time-Stamp Counter," and see Table 35-2. |
| 17H | 23 | IA32_PLATFORM_ID | Shared | **Platform ID (R)**<br>See Table 35-2. |

**Table 35-6. Common MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)**

| Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 17H | 23 | MSR_PLATFORM_ID | Shared | **Model Specific Platform ID (R)** |
| | | 7:0 | | Reserved. |
| | | 12:8 | | **Maximum Qualified Ratio (R)**<br>The maximum allowed bus ratio. |
| | | 49:13 | | Reserved. |
| | | 52:50 | | **See** Table 35-2 |
| | | 63:33 | | Reserved. |

| | | 14:0 | | Thermal Spec Power. (R/O)<br>The unsigned integer value is the equivalent of thermal specification power of the package domain. The unit of this field is specified by the "Power Units" field of MSR_RAPL_POWER_UNIT |
| | | 63:15 | | Reserved |

## 35.5 MSRS IN THE INTEL® MICROARCHITECTURE CODE NAME NEHALEM

Table 35-10 lists model-specific registers (MSRs) that are common for Intel® microarchitecture code name Nehalem. These include Intel Core i7 and i5 processor family. Architectural MSR addresses are also included in Table 35-10. These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_1AH, 06_1EH, 06_1FH, 06_2EH, see Table 35-1. Additional MSRs specific to 06_1AH, 06_1EH, 06_1FH are listed in Table 35-11. Some MSRs listed in these tables are used by BIOS. More information about these MSR can be found at http://bios-bits.org.

The column "Scope" represents the package/core/thread scope of individual bit field of an MSR. "Thread" means this bit field must be programmed on each logical processor independently. "Core" means the bit field must be programmed on each processor core independently, logical processors in the same core will be affected by change of this bit on the other logical processor in the same core. "Package" means the bit field must be programmed once for each physical package. Change of a bit filed with a package scope will affect all logical processors in that physical package.

## Table 35-10. MSRs in Processors Based on Intel® Microarchitecture Code Name Nehalem

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 0H | 0 | IA32_P5_MC_ADDR | Thread | See Section 35.19, "MSRs in Pentium Processors." |
| 1H | 1 | IA32_P5_MC_TYPE | Thread | See Section 35.19, "MSRs in Pentium Processors." |
| 6H | 6 | IA32_MONITOR_FILTER_ SIZE | Thread | See Section 8.10.5, "Monitor/Mwait Address Range Determination," and Table 35-2. |
| 10H | 16 | IA32_TIME_ STAMP_COUNTER | Thread | See Section 17.13, "Time-Stamp Counter," and see Table 35-2. |
| 17H | 23 | IA32_PLATFORM_ID | Package | **Platform ID (R)**<br>See Table 35-2. |
| 17H | 23 | MSR_PLATFORM_ID | Package | **Model Specific Platform ID (R)** |
| | | 49:0 | | Reserved. |
| | | 52:50 | | See Table 35-2. |
| | | 63:53 | | Reserved. |
| 1BH | 27 | IA32_APIC_BASE | Thread | See Section 10.4.4, "Local APIC Status and Location," and Table 35-2. |
| 34H | 52 | MSR_SMI_COUNT | Thread | **SMI Counter (R/O)** |
| | | 31:0 | | **SMI Count (R/O)**<br>Running count of SMI events since last RESET. |
| | | 63:32 | | Reserved. |
| 3AH | 58 | IA32_FEATURE_CONTROL | Thread | **Control Features in Intel 64Processor (R/W)**<br>See Table 35-2. |
| 79H | 121 | IA32_BIOS_ UPDT_TRIG | Core | **BIOS Update Trigger Register (W)**<br>See Table 35-2. |
| 8BH | 139 | IA32_BIOS_ SIGN_ID | Thread | **BIOS Update Signature ID (RO)**<br>See Table 35-2. |
| C1H | 193 | IA32_PMC0 | Thread | **Performance Counter Register**<br>See Table 35-2. |
| C2H | 194 | IA32_PMC1 | Thread | **Performance Counter Register**<br>See Table 35-2. |
| C3H | 195 | IA32_PMC2 | Thread | **Performance Counter Register**<br>See Table 35-2. |
| C4H | 196 | IA32_PMC3 | Thread | **Performance Counter Register**<br>See Table 35-2. |
| CEH | 206 | MSR_PLATFORM_INFO | Package | see http://biosbits.org. |
| | | 7:0 | | Reserved. |

## Table 35-10. MSRs in Processors Based on Intel® Microarchitecture Code Name Nehalem (Contd.)

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| | | 15:8 | Package | **Maximum Non-Turbo Ratio (R/O)**<br>The is the ratio of the frequency that invariant TSC runs at. The invariant TSC frequency can be computed by multiplying this ratio by 133.33 MHz. |
| | | 27:16 | | Reserved. |
| | | 28 | Package | **Programmable Ratio Limit for Turbo Mode (R/O)**<br>When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled. |
| | | 29 | Package | **Programmable TDC-TDP Limit for Turbo Mode (R/O)**<br>When set to 1, indicates that TDC/TDP Limits for Turbo mode are programmable, and when set to 0, indicates TDC and TDP Limits for Turbo mode are not programmable. |
| | | 39:30 | | Reserved. |
| | | 47:40 | Package | **Maximum Efficiency Ratio (R/O)**<br>The is the minimum ratio (maximum efficiency) that the processor can operates, in units of 133.33MHz. |
| | | 63:48 | | Reserved. |
| E2H | 226 | MSR_PKG_CST_CONFIG_ CONTROL | Core | **C-State Configuration Control (R/W)**<br>Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States. See http://biosbits.org. |
| | | 2:0 | | **Package C-State Limit (R/W)**<br>Specifies the lowest processor-specific C-state code name (consuming the least power). for the package. The default is set as factory-configured package C-state limit.<br>The following C-state code name encodings are supported:<br>000b: C0 (no package C-sate support)<br>001b: C1 (Behavior is the same as 000b)<br>010b: C3<br>011b: C6<br>100b: C7<br>101b and 110b: Reserved<br>111: No package C-state limit.<br>Note: This field cannot be used to limit package C-state to C3. |
| | | 9:3 | | Reserved. |
| | | 10 | | **I/O MWAIT Redirection Enable (R/W)**<br>When set, will map IO_read instructions sent to IO register specified by MSR_PMG_IO_CAPTURE_BASE to MWAIT instructions. |
| | | 14:11 | | Reserved. |
| | | 15 | | **CFG Lock (R/WO)**<br>When set, lock bits 15:0 of this register until next reset. |

## Table 35-10. MSRs in Processors Based on Intel® Microarchitecture Code Name Nehalem (Contd.)

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| | | 23:16 | | Reserved. |
| | | 24 | | **Interrupt filtering enable (R/W)**<br>When set, processor cores in a deep C-State will wake only when the event message is destined for that core. When 0, all processor cores in a deep C-State will wake for an event message. |
| | | 25 | | **C3 state auto demotion enable (R/W)**<br>When set, the processor will conditionally demote C6/C7 requests to C3 based on uncore auto-demote information. |
| | | 26 | | **C1 state auto demotion enable (R/W)**<br>When set, the processor will conditionally demote C3/C6/C7 requests to C1 based on uncore auto-demote information. |
| | | 63:27 | | Reserved. |
| E4H | 228 | MSR_PMG_IO_CAPTURE_BASE | Core | **Power Management IO Redirection in C-state (R/W)**<br>See http://biosbits.org. |
| | | 15:0 | | **LVL_2 Base Address (R/W)**<br>Specifies the base address visible to software for IO redirection. If IO MWAIT Redirection is enabled, reads to this address will be consumed by the power management logic and decoded to MWAIT instructions. When IO port address redirection is enabled, this is the IO port address reported to the OS/software. |
| | | 18:16 | | **C-state Range (R/W)**<br>Specifies the encoding value of the maximum C-State code name to be included when IO read to MWAIT redirection is enabled by MSR_PKG_CST_CONFIG_CONTROL[bit10]:<br>000b - C3 is the max C-State to include<br>001b - C6 is the max C-State to include<br>010b - C7 is the max C-State to include |
| | | 63:19 | | Reserved. |
| E7H | 231 | IA32_MPERF | Thread | **Maximum Performance Frequency Clock Count (RW)**<br>See Table 35-2. |
| E8H | 232 | IA32_APERF | Thread | **Actual Performance Frequency Clock Count (RW)**<br>See Table 35-2. |
| FEH | 254 | IA32_MTRRCAP | Thread | See Table 35-2. |
| 174H | 372 | IA32_SYSENTER_CS | Thread | See Table 35-2. |
| 175H | 373 | IA32_SYSENTER_ESP | Thread | See Table 35-2. |
| 176H | 374 | IA32_SYSENTER_EIP | Thread | See Table 35-2. |
| 179H | 377 | IA32_MCG_CAP | Thread | See Table 35-2. |
| 17AH | 378 | IA32_MCG_STATUS | Thread | |

## Table 35-10. MSRs in Processors Based on Intel® Microarchitecture Code Name Nehalem (Contd.)

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| | | 0 | | **RIPV**<br>When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If cleared, the program cannot be reliably restarted. |
| | | 1 | | **EIPV**<br>When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error. |
| | | 2 | | **MCIP**<br>When set, bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception. |
| | | 63:3 | | Reserved. |
| 186H | 390 | IA32_PERFEVTSEL0 | Thread | See Table 35-2. |

## 35.5.1 Additional MSRs in the Intel® Xeon® Processor 5500 and 3400 Series

Intel Xeon Processor 5500 and 3400 series support additional model-specific registers listed in Table 35-11. These MSRs also apply to Intel Core i7 and i5 processor family CPUID signature with DisplayFamily_DisplayModel of 06_1AH, 06_1EH and 06_1FH, see Table 35-1.

### Table 35-11. Additional MSRs in Intel® Xeon® Processor 5500 and 3400 Series

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 1ADH | 429 | MSR_TURBO_RATIO_LIMIT | Package | Actual maximum turbo frequency is multiplied by 133.33MHz. (not available to model 06_2EH) |
| | | 7:0 | | **Maximum Turbo Ratio Limit 1C (R/O)**<br>Maximum Turbo mode ratio limit with 1 core active. |
| | | 15:8 | | **Maximum Turbo Ratio Limit 2C (R/O)**<br>Maximum Turbo mode ratio limit with 2cores active. |
| | | 23:16 | | **Maximum Turbo Ratio Limit 3C (R/O)**<br>Maximum Turbo mode ratio limit with 3cores active. |
| | | 31:24 | | **Maximum Turbo Ratio Limit 4C (R/O)**<br>Maximum Turbo mode ratio limit with 4 cores active. |
| | | 63:32 | | Reserved. |
| 301H | 769 | MSR_GQ_SNOOP_MESF | Package | |
| | | 0 | | **From M to S (R/W)** |
| | | 1 | | **From E to S (R/W)** |

## 35.5.2 Additional MSRs in the Intel® Xeon® Processor 7500 Series

Intel Xeon Processor 7500 series support MSRs listed in Table 35-10 (except MSR address 1ADH) and additional model-specific registers listed in Table 35-12.

Table 35-12. Additional MSRs in Intel® Xeon® Processor 7500 Series

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 1ADH | 429 | MSR_TURBO_RATIO_LIMIT | Package | **Reserved**<br>Attempt to read/write will cause #UD. |
| 289H | 649 | IA32_MC9_CTL2 | Package | See Table 35-2. |
| 28AH | 650 | IA32_MC10_CTL2 | Package | See Table 35-2. |
| 28BH | 651 | IA32_MC11_CTL2 | Package | See Table 35-2. |
| 28CH | 652 | IA32_MC12_CTL2 | Package | See Table 35-2. |

**Table 35-12. Additional MSRs in Intel® Xeon® Processor 7500 Series (Contd.)**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 28DH | 653 | IA32_MC13_CTL2 | Package | See Table 35-2. |
| 28EH | 654 | IA32_MC14_CTL2 | Package | See Table 35-2. |
| 28FH | 655 | IA32_MC15_CTL2 | Package | See Table 35-2. |

## 35.6 MSRS IN THE INTEL® XEON® PROCESSOR 5600 SERIES (BASED ON INTEL® MICROARCHITECTURE CODE NAME WESTMERE)

Intel® Xeon® Processor 5600 Series (based on Intel® microarchitecture code name Westmere) supports the MSR interfaces listed in Table 35-10, Table 35-11, plus additional MSR listed in Table 35-13. These MSRs also apply to Intel Core i7, i5 and i3 processor family with CPUID signature DisplayFamily_DisplayModel of 06_25H and 06_2CH, see Table 35-1.

## 35.7 MSRS IN THE INTEL® XEON® PROCESSOR E7 FAMILY (BASED ON INTEL® MICROARCHITECTURE CODE NAME WESTMERE)

Intel® Xeon® Processor E7 Family (based on Intel® microarchitecture code name Westmere) supports the MSR interfaces listed in Table 35-10 (except MSR address 1ADH), Table 35-11, plus additional MSR listed in Table 35-14.

## 35.8 MSRS IN INTEL® PROCESSOR FAMILY BASED ON INTEL® MICROARCHITECTURE CODE NAME SANDY BRIDGE

Table 35-15 lists model-specific registers (MSRs) that are common to Intel® processor family based on Intel micro-architecture code name Sandy Bridge. All architectural MSRs listed in Table 35-2 are supported. These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_2AH, 06_2DH, see Table 35-1. Additional MSRs specific to 06_2AH are listed in Table 35-16.

**Table 35-15. MSRs Supported by Intel® Processors based on Intel® microarchitecture code name Sandy Bridge**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 0H | 0 | IA32_P5_MC_ADDR | Thread | See Section 35.19, "MSRs in Pentium Processors." |
| 1H | 1 | IA32_P5_MC_TYPE | Thread | See Section 35.19, "MSRs in Pentium Processors." |
| 6H | 6 | IA32_MONITOR_FILTER_SIZE | Thread | See Section 8.10.5, "Monitor/Mwait Address Range Determination," and Table 35-2. |
| 10H | 16 | IA32_TIME_STAMP_COUNTER | Thread | See Section 17.13, "Time-Stamp Counter," and see Table 35-2. |
| 17H | 23 | IA32_PLATFORM_ID | Package | **Platform ID (R)**<br>See Table 35-2. |

| CEH | 206 | MSR_PLATFORM_INFO | Package | See http://biosbits.org. |
| | | 7:0 | | Reserved. |
| | | 15:8 | Package | **Maximum Non-Turbo Ratio (R/O)**<br>The is the ratio of the frequency that invariant TSC runs at. Frequency = ratio * 100 MHz. |
| | | 27:16 | | Reserved. |
| | | 28 | Package | **Programmable Ratio Limit for Turbo Mode (R/O)**<br>When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled. |
| | | 29 | Package | **Programmable TDP Limit for Turbo Mode (R/O)**<br>When set to 1, indicates that TDP Limits for Turbo mode are programmable, and when set to 0, indicates TDP Limit for Turbo mode is not programmable. |
| | | 39:30 | | Reserved. |
| | | 47:40 | Package | **Maximum Efficiency Ratio (R/O)**<br>The is the minimum ratio (maximum efficiency) that the processor can operates, in units of 100MHz. |
| | | 63:48 | | Reserved. |

## Table 35-15. MSRs Supported by Intel® Processors based on Intel® microarchitecture code name Sandy Bridge (Contd.)

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| E2H | 226 | MSR_PKG_CST_CONFIG_ CONTROL | Core | **C-State Configuration Control (R/W)**<br>Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.<br>See http://biosbits.org. |
| | | 2:0 | | **Package C-State Limit (R/W)**<br>Specifies the lowest processor-specific C-state code name (consuming the least power). for the package. The default is set as factory-configured package C-state limit.<br>The following C-state code name encodings are supported:<br>000b: C0/C1 (no package C-sate support)<br>001b: C2<br>010b: C6 no retention<br>011b: C6 retention<br>100b: C7<br>101b: C7s<br>111: No package C-state limit.<br>Note: This field cannot be used to limit package C-state to C3. |
| | | 9:3 | | Reserved. |
| | | 10 | | **I/O MWAIT Redirection Enable (R/W)**<br>When set, will map IO_read instructions sent to IO register specified by MSR_PMG_IO_CAPTURE_BASE to MWAIT instructions |
| | | 14:11 | | Reserved. |
| | | 15 | | **CFG Lock (R/WO)**<br>When set, lock bits 15:0 of this register until next reset. |
| | | 24:16 | | Reserved. |
| | | 25 | | **C3 state auto demotion enable (R/W)**<br>When set, the processor will conditionally demote C6/C7 requests to C3 based on uncore auto-demote information. |
| | | 26 | | **C1 state auto demotion enable (R/W)**<br>When set, the processor will conditionally demote C3/C6/C7 requests to C1 based on uncore auto-demote information. |
| | | 27 | | **Enable C3 undemotion (R/W)**<br>When set, enables undemotion from demoted C3. |
| | | 28 | | **Enable C1 undemotion (R/W)**<br>When set, enables undemotion from demoted C1. |
| | | 63:29 | | Reserved. |
| E4H | 228 | MSR_PMG_IO_CAPTURE_ BASE | Core | **Power Management IO Redirection in C-state (R/W)**<br>See http://biosbits.org. |

**Table 35-15. MSRs Supported by Intel® Processors based on Intel® microarchitecture code name Sandy Bridge (Contd.)**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| | | 15:0 | | **LVL_2 Base Address (R/W)**<br>Specifies the base address visible to software for IO redirection. If IO MWAIT Redirection is enabled, reads to this address will be consumed by the power management logic and decoded to MWAIT instructions. When IO port address redirection is enabled, this is the IO port address reported to the OS/software. |
| | | 18:16 | | **C-state Range (R/W)**<br>Specifies the encoding value of the maximum C-State code name to be included when IO read to MWAIT redirection is enabled by MSR_PKG_CST_CONFIG_CONTROL[bit10]:<br>000b - C3 is the max C-State to include<br>001b - C6 is the max C-State to include<br>010b - C7 is the max C-State to include |

## 35.8.1 MSRs In 2nd Generation Intel® Core™ Processor Family (Based on Intel® Microarchitecture Code Name Sandy Bridge)

Table 35-16 lists model-specific registers (MSRs) that are specific to the 2nd generation Intel® Core™ processor family (based on Intel microarchitecture code name Sandy Bridge). These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_2AH, see Table 35-1.

### Table 35-16. MSRs Supported by 2nd Generation Intel® Core™ Processors (Intel® microarchitecture code name Sandy Bridge)

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 1ADH | 429 | MSR_TURBO_RATIO_LIMIT | Package | **Maximum Ratio Limit of Turbo Mode**<br>RO if MSR_PLATFORM_INFO.[28] = 0,<br>RW if MSR_PLATFORM_INFO.[28] = 1 |
| | | 7:0 | Package | **Maximum Ratio Limit for 1C**<br>Maximum turbo ratio limit of 1 core active. |
| | | 15:8 | Package | **Maximum Ratio Limit for 2C**<br>Maximum turbo ratio limit of 2 core active. |
| | | 23:16 | Package | **Maximum Ratio Limit for 3C**<br>Maximum turbo ratio limit of 3 core active. |
| | | 31:24 | Package | **Maximum Ratio Limit for 4C**<br>Maximum turbo ratio limit of 4 core active. |
| | | 63:32 | | Reserved. |
| 391H | 913 | MSR_UNC_PERF_GLOBAL_CTRL | Package | Uncore PMU global control |
| | | 0 | | Core 0 select |
| | | 1 | | Core 1 select |
| | | 2 | | Core 2 select |
| | | 3 | | Core 3 select |
| | | 18:4 | | Reserved. |
| | | 29 | | Enable all uncore counters |
| | | 30 | | Enable wake on PMI |
| | | 31 | | Enable Freezing counter when overflow |
| | | 63:32 | | Reserved. |
| 392H | 914 | MSR_UNC_PERF_GLOBAL_STATUS | Package | Uncore PMU main status |
| | | 0 | | Fixed counter overflowed |
| | | 1 | | An ARB counter overflowed |
| | | 2 | | Reserved |
| | | 3 | | A CBox counter overflowed (on any slice) |
| | | 63:4 | | Reserved. |
| 394H | 916 | MSR_UNC_PERF_FIXED_CTRL | Package | Uncore fixed counter control (R/W) |
| | | 19:0 | | Reserved |
| | | 20 | | Enable overflow propagation |
| | | 21 | | Reserved |
| | | 22 | | Enable counting |
| | | 63:23 | | Reserved. |

**Table 35-16. MSRs Supported by 2nd Generation Intel® Core™ Processors (Intel® microarchitecture code name Sandy Bridge) (Contd.)**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 395H | 917 | MSR_UNC_PERF_FIXED_ CTR | Package | Uncore fixed counter |
| | | 47:0 | | Current count |
| | | 63:48 | | Reserved. |
| 396H | 918 | MSR_UNC_CBO_CONFIG | Package | Uncore C-Box configuration information (R/O) |
| | | 3:0 | | Encoded number of C-Box, derive value by "-1" |
| | | 63:4 | | Reserved. |
| 3B0H | 946 | MSR_UNC_ARB_PER_CTR0 | Package | Uncore Arb unit, performance counter 0 |
| 3B1H | 947 | MSR_UNC_ARB_PER_CTR1 | Package | Uncore Arb unit, performance counter 1 |
| 3B2H | 944 | MSR_UNC_ARB_ PERFEVTSEL0 | Package | Uncore Arb unit, counter 0 event select MSR |
| 3B3H | 945 | MSR_UNC_ARB_ PERFEVTSEL1 | Package | Uncore Arb unit, counter 1 event select MSR |
| 60CH | 1548 | MSR_PKGC7_IRTL | Package | **Package C7 Interrupt Response Limit (R/W)**<br>This MSR defines the budget allocated for the package to exit from C7 to a C0 state, where interrupt request can be delivered to the core and serviced. Additional core-exit latency amy be applicable depending on the actual C-state the core is in.<br>Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States. |
| | | 9:0 | | **Interrupt response time limit (R/W)**<br>Specifies the limit that should be used to decide if the package should be put into a package C7 state. |
| | | 12:10 | | **Time Unit (R/W)**<br>Specifies the encoding value of time unit of the interrupt response time limit. The following time unit encodings are supported:<br>000b: 1 ns<br>001b: 32 ns<br>010b: 1024 ns<br>011b: 32768 ns<br>100b: 1048576 ns<br>101b: 33554432 ns |
| | | 14:13 | | Reserved. |
| | | 15 | | **Valid (R/W)**<br>Indicates whether the values in bits 12:0 are valid and can be used by the processor for package C-sate management. |
| | | 63:16 | | Reserved. |
| 63AH | 1594 | MSR_PP0_POLICY | Package | **PP0 Balance Policy (R/W)**<br>See Section 14.9.4, "PP0/PP1 RAPL Domains." |

## Table 35-16. MSRs Supported by 2nd Generation Intel® Core™ Processors (Intel® microarchitecture code name Sandy Bridge) (Contd.)

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 63BH | 1595 | MSR_PP0_PERF_STATUS | Package | **PP0 Performance Throttling Status (R/O)** See Section 14.9.4, "PP0/PP1 RAPL Domains." |
| 640H | 1600 | MSR_PP1_POWER_LIMIT | Package | **PP1 RAPL Power Limit Control (R/W)** See Section 14.9.4, "PP0/PP1 RAPL Domains." |
| 641H | 1601 | MSR_PP1_ENERGY_STATUS | Package | **PP1 Energy Status (R/O)** See Section 14.9.4, "PP0/PP1 RAPL Domains." |
| 642H | 1602 | MSR_PP1_POLICY | Package | **PP1 Balance Policy (R/W)** See Section 14.9.4, "PP0/PP1 RAPL Domains." |
| 700H | 1792 | MSR_UNC_CBO_0_ PERFEVTSEL0 | Package | Uncore C-Box 0, counter 0 event select MSR |
| 701H | 1793 | MSR_UNC_CBO_0_ PERFEVTSEL1 | Package | Uncore C-Box 0, counter 1 event select MSR |
| 706H | 1798 | MSR_UNC_CBO_0_PER_ CTR0 | Package | Uncore C-Box 0, performance counter 0 |
| 707H | 1799 | MSR_UNC_CBO_0_PER_ CTR1 | Package | Uncore C-Box 0, performance counter 1 |
| 710H | 1808 | MSR_UNC_CBO_1_ PERFEVTSEL0 | Package | Uncore C-Box 1, counter 0 event select MSR |
| 711H | 1809 | MSR_UNC_CBO_1_ PERFEVTSEL1 | Package | Uncore C-Box 1, counter 1 event select MSR |
| 716H | 1814 | MSR_UNC_CBO_1_PER_ CTR0 | Package | Uncore C-Box 1, performance counter 0 |
| 717H | 1815 | MSR_UNC_CBO_1_PER_ CTR1 | Package | Uncore C-Box 1, performance counter 1 |
| 720H | 1824 | MSR_UNC_CBO_2_ PERFEVTSEL0 | Package | Uncore C-Box 2, counter 0 event select MSR |
| 721H | 1824 | MSR_UNC_CBO_2_ PERFEVTSEL1 | Package | Uncore C-Box 2, counter 1 event select MSR |
| 726H | 1830 | MSR_UNC_CBO_2_PER_ CTR0 | Package | Uncore C-Box 2, performance counter 0 |
| 727H | 1831 | MSR_UNC_CBO_2_PER_ CTR1 | Package | Uncore C-Box 2, performance counter 1 |
| 730H | 1840 | MSR_UNC_CBO_3_ PERFEVTSEL0 | Package | Uncore C-Box 3, counter 0 event select MSR |
| 731H | 1841 | MSR_UNC_CBO_3_ PERFEVTSEL1 | Package | Uncore C-Box 3, counter 1 event select MSR. |
| 736H | 1846 | MSR_UNC_CBO_3_PER_ CTR0 | Package | Uncore C-Box 3, performance counter 0. |
| 737H | 1847 | MSR_UNC_CBO_3_PER_ CTR1 | Package | Uncore C-Box 3, performance counter 1. |

### 35.8.2 MSRs In Intel® Xeon® Processor E5 Family (Based on Intel® Microarchitecture Code Name Sandy Bridge)

Table 35-17 lists selected model-specific registers (MSRs) that are specific to the Intel® Xeon® Processor E5 Family (based on Intel® microarchitecture code name Sandy Bridge). These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_2DH, see Table 35-1.

**Table 35-17. Selected MSRs Supported by Intel® Xeon® Processors E5 Family (based on Intel® microarchitecture code name Sandy Bridge)**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 17FH | 383 | MSR_ERROR_CONTROL | Package | **MC Bank Error Configuration (R/W)** |
| | | 0 | | Reserved |
| | | 1 | | **MemError Log Enable (R/W)**<br>When set, enables IMC status bank to log additional info in bits 36:32. |
| | | 63:2 | | Reserved. |
| 1ADH | 429 | MSR_TURBO_RATIO_LIMIT | Package | **Maximum Ratio Limit of Turbo Mode**<br>RO if MSR_PLATFORM_INFO.[28] = 0,<br>RW if MSR_PLATFORM_INFO.[28] = 1 |
| | | 7:0 | Package | **Maximum Ratio Limit for 1C**<br>Maximum turbo ratio limit of 1 core active. |
| | | 15:8 | Package | **Maximum Ratio Limit for 2C**<br>Maximum turbo ratio limit of 2 core active. |
| | | 23:16 | Package | **Maximum Ratio Limit for 3C**<br>Maximum turbo ratio limit of 3 core active. |
| | | 31:24 | Package | **Maximum Ratio Limit for 4C**<br>Maximum turbo ratio limit of 4 core active. |
| | | 39:32 | Package | **Maximum Ratio Limit for 5C**<br>Maximum turbo ratio limit of 5 core active. |
| | | 47:40 | Package | **Maximum Ratio Limit for 6C**<br>Maximum turbo ratio limit of 6 core active. |
| | | 55:48 | Package | **Maximum Ratio Limit for 7C**<br>Maximum turbo ratio limit of 7 core active. |
| | | 63:56 | Package | **Maximum Ratio Limit for 8C**<br>Maximum turbo ratio limit of 8 core active. |
| 285H | 645 | IA32_MC5_CTL2 | Package | See Table 35-2. |
| 286H | 646 | IA32_MC6_CTL2 | Package | See Table 35-2. |
| 287H | 647 | IA32_MC7_CTL2 | Package | See Table 35-2. |
| 288H | 648 | IA32_MC8_CTL2 | Package | See Table 35-2. |
| 289H | 649 | IA32_MC9_CTL2 | Package | See Table 35-2. |
| 28AH | 650 | IA32_MC10_CTL2 | Package | See Table 35-2. |
| 28BH | 651 | IA32_MC11_CTL2 | Package | See Table 35-2. |
| 28CH | 652 | IA32_MC12_CTL2 | Package | See Table 35-2. |

**Table 35-17. Selected MSRs Supported by Intel® Xeon® Processors E5 Family (based on Intel® microarchitecture code name Sandy Bridge) (Contd.)**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 28DH | 653 | IA32_MC13_CTL2 | Package | See Table 35-2. |
| 28EH | 654 | IA32_MC14_CTL2 | Package | See Table 35-2. |

## 35.9.1 MSRs In Intel® Xeon® Processor E5 v2 Product Family (Based on Ivy Bridge-E Microarchitecture)

Table 35-19 lists model-specific registers (MSRs) that are specific to the Intel® Xeon® Processor E5 v2 Product Family (based on Ivy Bridge-E microarchitecture). These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_3EH, see Table 35-1. These processors supports the MSR interfaces listed in Table 35-15, and Table 35-19.

**Table 35-19. MSRs Supported by Intel® Xeon® Processors E5 v2 Product Family (based on Ivy Bridge-E microarchitecture)**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 4EH | 78 | MSR_PPIN_CTL | Package | Protected Processor Inventory Number Enable Control (R/W) |

**Table 35-19. MSRs Supported by Intel® Xeon® Processors E5 v2 Product Family (based on Ivy Bridge-E microarchitecture) (Contd.)**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| | | 0 | | LockOut (R/WO)<br>Set 1to prevent further writes to MSR_PPIN_CTL. Writing 1 to MSR_PPINCTL[bit 0] is permitted only if MSR_PPIN_CTL[bit 1] is clear, Default is 0.<br>BIOS should provide an opt-in menu to enable the user to turn on MSR_PPIN_CTL[bit 1] for privileged inventory initialization agent to access MSR_PPIN. After reading MSR_PPIN, the privileged inventory initialization agent should write '01b' to MSR_PPIN_CTL to disable further access to MSR_PPIN and prevent unauthorized modification to MSR_PPIN_CTL. |
| | | 1 | | Enable_PPIN (R/W)<br>If 1, enables MSR_PPIN to be accessible using RDMSR. Once set, attempt to write 1 to MSR_PPIN_CTL[bit 0] will cause #GP.<br>If 0, an attempt to read MSR_PPIN will cause #GP. Default is 0. |
| | | 63:2 | | Reserved. |
| 4FH | 79 | MSR_PPIN | Package | Protected Processor Inventory Number (R/O) |
| | | 63:0 | | **Protected Processor Inventory Number (R/O)**<br>A unique value within a given CPUID family/model/stepping signature that a privileged inventory initialization agent can access to identify each physical processor, when access to MSR_PPIN is enabled. Access to MSR_PPIN is permitted only if MSR_PPIN_CTL[bits 1:0] = '10b' |
| CEH | 206 | MSR_PLATFORM_INFO | Package | See http://biosbits.org. |
| | | 7:0 | | Reserved. |
| | | 15:8 | Package | **Maximum Non-Turbo Ratio (R/O)**<br>The is the ratio of the frequency that invariant TSC runs at. Frequency = ratio * 100 MHz. |
| | | 22:16 | | Reserved. |
| | | 23 | Package | **PPIN_CAP (R/O)**<br>When set to 1, indicates that Protected Processor Inventory Number (PPIN) capability can be enabled for privileged system inventory agent to read PPIN from MSR_PPIN.<br>When set to 0, PPIN capability is not supported. An attempt to access MSR_PPIN_CTL or MSR_PPIN will cause #GP. |
| | | 27:24 | | Reserved. |
| | | 28 | Package | **Programmable Ratio Limit for Turbo Mode (R/O)**<br>When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled. |

## 35.10 MSRS IN THE 4TH GENERATION INTEL® CORE™ PROCESSORS (BASED ON HASWELL MICROARCHITECTURE)

The 4th generation Intel® Core™ processor family and Intel® Xeon® processor E3-1200v3 product family (based on Haswell microarchitecture), with CPUID DisplayFamily_DisplayModel signature 06_3CH/06_45H/06_46H, support the MSR interfaces listed in Table 35-15, Table 35-16, Table 35-18, and Table 35-21.

The MSRs listed in Table 35-21 also apply to processors based on Haswell-E microarchitecture (see Section 35.11).

**Table 35-21. Additional MSRs Supported by Processors based on the Haswell or Haswell-E microarchitectures**

## 35.10.1 MSRs in 4th Generation Intel® Core™ Processor Family (based on Haswell Microarchitecture)

Table 35-22 lists model-specific registers (MSRs) that are specific to 4th generation Intel® Core™ processor family and Intel® Xeon® processor E3-1200 v3 product family (based on Haswell microarchitecture). These processors have a CPUID signature with DisplayFamily_DisplayModel of 06_3CH/06_45H/06_46H, see Table 35-1.

**Table 35-22. MSRs Supported by 4th Generation Intel® Core™ Processors (Haswell microarchitecture)**

| Register Address | | Register Name | Scope | Bit Description |
|---|---|---|---|---|

## 35.15 MSRS IN THE PENTIUM® 4 AND INTEL® XEON® PROCESSORS

Table 35-28 lists MSRs (architectural and model-specific) that are defined across processor generations based on Intel NetBurst microarchitecture. The processor can be identified by its CPUID signatures of DisplayFamily encoding of 0FH, see Table 35-1.

- MSRs with an "IA32_" prefix are designated as "architectural." This means that the functions of these MSRs and their addresses remain the same for succeeding families of IA-32 processors.
- MSRs with an "MSR_" prefix are model specific with respect to address functionalities. The column "Model Availability" lists the model encoding value(s) within the Pentium 4 and Intel Xeon processor family at the specified register address. The model encoding value of a processor can be queried using CPUID. See "CPUID—CPU Identification" in Chapter 3 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*.

**Table 35-28. MSRs in the Pentium® 4 and Intel® Xeon® Processors**

| Register Address | | Register Name Fields and Flags | Model Avail-ability | Shared/ Unique[1] | Bit Description |
|---|---|---|---|---|---|
| Hex | Dec | | | | |
| 0H | 0 | IA32_P5_MC_ADDR | 0, 1, 2, 3, 4, 6 | Shared | See Section 35.19, "MSRs in Pentium Processors." |
| 1H | 1 | IA32_P5_MC_TYPE | 0, 1, 2, 3, 4, 6 | Shared | See Section 35.19, "MSRs in Pentium Processors." |
| 6H | 6 | IA32_MONITOR_FILTER_LINE_ SIZE | 3, 4, 6 | Shared | See Section 8.10.5, "Monitor/Mwait Address Range Determination." |
| 10H | 16 | IA32_TIME_STAMP_COUNTER | 0, 1, 2, 3, 4, 6 | Unique | **Time Stamp Counter**<br>See Table 35-2. |
| | | | | | On earlier processors, only the lower 32 bits are writable. On any write to the lower 32 bits, the upper 32 bits are cleared. For processor family 0FH, models 3 and 4: all 64 bits are writable. |
| 17H | 23 | IA32_PLATFORM_ID | 0, 1, 2, 3, 4, 6 | Shared | **Platform ID (R)**<br>See Table 35-2.<br>The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load. |
| 1BH | 27 | IA32_APIC_BASE | 0, 1, 2, 3, 4, 6 | Unique | **APIC Location and Status (R/W)**<br>See Table 35-2. See Section 10.4.4, "Local APIC Status and Location." |
| 2AH | 42 | MSR_EBC_HARD_POWERON | 0, 1, 2, 3, 4, 6 | Shared | **Processor Hard Power-On Configuration**<br>**(R/W)** Enables and disables processor features;<br>**(R)** indicates current processor configuration. |
| | | 0 | | | **Output Tri-state Enabled (R)**<br>Indicates whether tri-state output is enabled (1) or disabled (0) as set by the strapping of SMI#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted. |
| | | 1 | | | **Execute BIST (R)**<br>Indicates whether the execution of the BIST is enabled (1) or disabled (0) as set by the strapping of INIT#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted. |

Table 35-28. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

| Register Address | | Register Name Fields and Flags | Model Avail-ability | Shared/ Unique[1] | Bit Description |
|---|---|---|---|---|---|
| Hex | Dec | | | | |
| | | 2 | | | **In Order Queue Depth (R)**<br>Indicates whether the in order queue depth for the system bus is 1 (1) or up to 12 (0) as set by the strapping of A7#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted. |
| | | 3 | | | **MCERR# Observation Disabled (R)**<br>Indicates whether MCERR# observation is enabled (0) or disabled (1) as determined by the strapping of A9#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted. |
| | | 4 | | | **BINIT# Observation Enabled (R)**<br>Indicates whether BINIT# observation is enabled (0) or disabled (1) as determined by the strapping of A10#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted. |
| | | 6:5 | | | **APIC Cluster ID (R)**<br>Contains the logical APIC cluster ID value as set by the strapping of A12# and A11#. The logical cluster ID value is written into the field on the deassertion of RESET#; the field is set to 1 when the address bus signal is asserted. |
| | | 7 | | | **Bus Park Disable (R)**<br>Indicates whether bus park is enabled (0) or disabled (1) as set by the strapping of A15#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted. |
| | | 11:8 | | | Reserved. |
| | | 13:12 | | | **Agent ID (R)**<br>Contains the logical agent ID value as set by the strapping of BR[3:0]. The logical ID value is written into the field on the deassertion of RESET#; the field is set to 1 when the address bus signal is asserted. |
| | | 63:14 | | | Reserved. |
| 2BH | 43 | MSR_EBC_SOFT_POWERON | 0, 1, 2, 3, 4, 6 | Shared | **Processor Soft Power-On Configuration (R/W)**<br>Enables and disables processor features. |
| | | 0 | | | **RCNT/SCNT On Request Encoding Enable (R/W)**<br>Controls the driving of RCNT/SCNT on the request encoding. Set to enable (1); clear to disabled (0, default). |

Table 35-28. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

| Register Address | | Register Name Fields and Flags | Model Avail-ability | Shared/ Unique[1] | Bit Description |
|---|---|---|---|---|---|
| Hex | Dec | | | | |
| | | 1 | | | **Data Error Checking Disable (R/W)**<br>Set to disable system data bus parity checking; clear to enable parity checking. |
| | | 2 | | | **Response Error Checking Disable (R/W)**<br>Set to disable (default); clear to enable. |
| | | 3 | | | **Address/Request Error Checking Disable (R/W)**<br>Set to disable (default); clear to enable. |
| | | 4 | | | **Initiator MCERR# Disable (R/W)**<br>Set to disable MCERR# driving for initiator bus requests (default); clear to enable. |
| | | 5 | | | **Internal MCERR# Disable (R/W)**<br>Set to disable MCERR# driving for initiator internal errors (default); clear to enable. |
| | | 6 | | | **BINIT# Driver Disable (R/W)**<br>Set to disable BINIT# driver (default); clear to enable driver. |
| | | 63:7 | | | Reserved. |
| 2CH | 44 | MSR_EBC_FREQUENCY_ID | 2,3, 4, 6 | Shared | **Processor Frequency Configuration**<br>The bit field layout of this MSR varies according to the MODEL value in the CPUID version information. The following bit field layout applies to Pentium 4 and Xeon Processors with MODEL encoding equal or greater than 2.<br>(R) The field Indicates the current processor frequency configuration. |
| | | 15:0 | | | Reserved. |
| | | 18:16 | | | **Scalable Bus Speed (R/W)**<br>Indicates the intended scalable bus speed:<br>Encoding Scalable Bus Speed<br>000B 100 MHz (Model 2)<br>000B 266 MHz (Model 3 or 4)<br>001B 133 MHz<br>010B 200 MHz<br>011B 166 MHz<br>100B 333 MHz (Model 6)<br><br>133.33 MHz should be utilized if performing calculation with System Bus Speed when encoding is 001B.<br>166.67 MHz should be utilized if performing calculation with System Bus Speed when encoding is 011B. |

**Table 35-28. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)**

| Register Address | | Register Name Fields and Flags | Model Avail-ability | Shared/ Unique[1] | Bit Description |
|---|---|---|---|---|---|
| Hex | Dec | | | | |
| | | | | | 266.67 MHz should be utilized if performing calculation with System Bus Speed when encoding is 000B and model encoding = 3 or 4.<br>333.33 MHz should be utilized if performing calculation with System Bus Speed when encoding is 100B and model encoding = 6.<br>All other values are reserved. |
| | | 23:19 | | | Reserved. |
| | | 31:24 | | | **Core Clock Frequency to System Bus Frequency Ratio (R)**<br>The processor core clock frequency to system bus frequency ratio observed at the de-assertion of the reset pin. |
| | | 63:25 | | | Reserved. |
| 2CH | 44 | MSR_EBC_FREQUENCY_ID | 0, 1 | Shared | **Processor Frequency Configuration (R)**<br>The bit field layout of this MSR varies according to the MODEL value of the CPUID version information. This bit field layout applies to Pentium 4 and Xeon Processors with MODEL encoding less than 2.<br>Indicates current processor frequency configuration. |
| | | 20:0 | | | Reserved. |
| | | 23:21 | | | **Scalable Bus Speed (R/W)**<br>Indicates the intended scalable bus speed:<br>Encoding Scalable Bus Speed<br>000B 100 MHz<br>All others values reserved. |

| | | 0 | | | Fast-Strings Enable. See Table 35-2. |
| | | 1 | | | Reserved. |
| | | 2 | | | **x87 FPU Fopcode Compatibility Mode Enable** |
| | | 3 | | | **Thermal Monitor 1 Enable**<br>See Section 14.7.2, "Thermal Monitor," and see Table 35-2. |
| | | 4 | | | **Split-Lock Disable**<br>When set, the bit causes an #AC exception to be issued instead of a split-lock cycle. Operating systems that set this bit must align system structures to avoid split-lock scenarios.<br>When the bit is clear (default), normal split-locks are issued to the bus. |
| | | | | | This debug feature is specific to the Pentium 4 processor. |
| | | 5 | | | Reserved. |
| | | 6 | | | **Third-Level Cache Disable (R/W)**<br>When set, the third-level cache is disabled; when clear (default) the third-level cache is enabled. This flag is reserved for processors that do not have a third-level cache.<br>Note that the bit controls only the third-level cache; and only if overall caching is enabled through the CD flag of control register CR0, the page-level cache controls, and/or the MTRRs.<br>See Section 11.5.4, "Disabling and Enabling the L3 Cache." |
| | | 7 | | | **Performance Monitoring Available (R)**<br>See Table 35-2. |
| | | 8 | | | **Suppress Lock Enable**<br>When set, assertion of LOCK on the bus is suppressed during a Split Lock access. When clear (default), LOCK is not suppressed. |

Table 35-28. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

| Register Address | | Register Name Fields and Flags | Model Avail-ability | Shared/ Unique[1] | Bit Description |
|---|---|---|---|---|---|
| Hex | Dec | | | | |
| | | 9 | | | **Prefetch Queue Disable**<br>When set, disables the prefetch queue. When clear (default), enables the prefetch queue. |
| | | 10 | | | **FERR# Interrupt Reporting Enable (R/W)**<br>When set, interrupt reporting through the FERR# pin is enabled; when clear, this interrupt reporting function is disabled. |
| | | | | | When this flag is set and the processor is in the stop-clock state (STPCLK# is asserted), asserting the FERR# pin signals to the processor that an interrupt (such as, INIT#, BINIT#, INTR, NMI, SMI#, or RESET#) is pending and that the processor should return to normal operation to handle the interrupt.<br>This flag does not affect the normal operation of the FERR# pin (to indicate an unmasked floating-point error) when the STPCLK# pin is not asserted. |
| | | 11 | | | **Branch Trace Storage Unavailable (BTS_UNAVILABLE) (R)**<br>See Table 35-2.<br>When set, the processor does not support branch trace storage (BTS); when clear, BTS is supported. |
| | | 12 | | | **PEBS_UNAVILABLE: Precise Event Based Sampling Unavailable (R)**<br>See Table 35-2.<br>When set, the processor does not support precise event-based sampling (PEBS); when clear, PEBS is supported. |
| | | 13 | 3 | | **TM2 Enable (R/W)**<br>When this bit is set (1) and the thermal sensor indicates that the die temperature is at the pre-determined threshold, the Thermal Monitor 2 mechanism is engaged. TM2 will reduce the bus to core ratio and voltage according to the value last written to MSR_THERM2_CTL bits 15:0.<br>When this bit is clear (0, default), the processor does not change the VID signals or the bus to core ratio when the processor enters a thermal managed state.<br>If the TM2 feature flag (ECX[8]) is not set to 1 after executing CPUID with EAX = 1, then this feature is not supported and BIOS must not alter the contents of this bit location. The processor is operating out of spec if both this bit and the TM1 bit are set to disabled states. |
| | | 17:14 | | | Reserved. |

| Register Address | | Register Name Fields and Flags | Model Avail-ability | Shared/ Unique[1] | Bit Description |
|---|---|---|---|---|---|
| Hex | Dec | | | | |
| | | 18 | 3, 4, 6 | | **ENABLE MONITOR FSM (R/W)**<br>See Table 35-2. |
| | | 19 | | | **Adjacent Cache Line Prefetch Disable (R/W)**<br>When set to 1, the processor fetches the cache line of the 128-byte sector containing currently required data. When set to 0, the processor fetches both cache lines in the sector. |
| | | | | | Single processor platforms should not set this bit. Server platforms should set or clear this bit based on platform performance observed in validation and testing.<br>BIOS may contain a setup option that controls the setting of this bit. |
| | | 21:20 | | | Reserved. |
| | | 22 | 3, 4, 6 | | **Limit CPUID MAXVAL (R/W)**<br>See Table 35-2.<br>Setting this can cause unexpected behavior to software that depends on the availability of CPUID leaves greater than 3. |
| | | 23 | | Shared | **xTPR Message Disable (R/W)**<br>See Table 35-2. |
| | | 24 | | | **L1 Data Cache Context Mode (R/W)**<br>When set, the L1 data cache is placed in shared mode; when clear (default), the cache is placed in adaptive mode. This bit is only enabled for IA-32 processors that support Intel Hyper-Threading Technology. See Section 11.5.6, "L1 Data Cache Context Mode."<br>When L1 is running in adaptive mode and CR3s are identical, data in L1 is shared across logical processors. Otherwise, L1 is not shared and cache use is competitive.<br>If the Context ID feature flag (ECX[10]) is set to 0 after executing CPUID with EAX = 1, the ability to switch modes is not supported. BIOS must not alter the contents of IA32_MISC_ENABLE[24]. |

| C000_0102H | | IA32_KERNEL_GSBASE | 3, 4, 6 | Unique | **Swap Target of BASE Address of GS (R/W)** See Table 35-2. |

NOTES

1. For HT-enabled processors, there may be more than one logical processors per physical unit. If an MSR is Shared, this means that one MSR is shared between logical processors. If an MSR is unique, this means that each logical processor has its own MSR.

## 35.15.1 MSRs Unique to Intel® Xeon® Processor MP with L3 Cache

The MSRs listed in Table 35-29 apply to Intel® Xeon® Processor MP with up to 8MB level three cache. These processors can be detected by enumerating the deterministic cache parameter leaf of CPUID instruction (with EAX = 4 as input) to detect the presence of the third level cache, and with CPUID reporting family encoding 0FH, model encoding 3 or 4 (see CPUID instruction for more details).

Table 35-29. MSRs Unique to 64-bit Intel® Xeon® Processor MP with Up to an 8 MB L3 Cache

| Register Address | | Register Name Fields and Flags | Model Avail-ability | Shared/ Unique | Bit Description |
|---|---|---|---|---|---|
| 107CCH | | MSR_IFSB_BUSQ0 | 3, 4 | Shared | **IFSB BUSQ Event Control and Counter Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache." |
| 107CDH | | MSR_IFSB_BUSQ1 | 3, 4 | Shared | **IFSB BUSQ Event Control and Counter Register (R/W)** |
| 107CEH | | MSR_IFSB_SNPQ0 | 3, 4 | Shared | **IFSB SNPQ Event Control and Counter Register (R/W)** See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache." |
| 107CFH | | MSR_IFSB_SNPQ1 | 3, 4 | Shared | **IFSB SNPQ Event Control and Counter Register (R/W)** |

### Table 35-29. MSRs Unique to 64-bit Intel® Xeon® Processor MP with Up to an 8 MB L3 Cache (Contd.)

| Register Address | | Register Name Fields and Flags | Model Availability | Shared/ Unique | Bit Description |
|---|---|---|---|---|---|
| 107D0H | | MSR_EFSB_DRDY0 | 3, 4 | Shared | **EFSB DRDY Event Control and Counter Register (R/W)**<br>See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache" for details. |
| 107D1H | | MSR_EFSB_DRDY1 | 3, 4 | Shared | **EFSB DRDY Event Control and Counter Register (R/W)** |
| 107D2H | | MSR_IFSB_CTL6 | 3, 4 | Shared | **IFSB Latency Event Control Register (R/W)**<br>See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache" for details. |
| 107D3H | | MSR_IFSB_CNTR7 | 3, 4 | Shared | **IFSB Latency Event Counter Register (R/W)**<br>See Section 18.18, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache." |

The MSRs listed in Table 35-30 apply to Intel® Xeon® Processor 7100 series. These processors can be detected by enumerating the deterministic cache parameter leaf of CPUID instruction (with EAX = 4 as input) to detect the presence of the third level cache, and with CPUID reporting family encoding 0FH, model encoding 6 (See CPUID instruction for more details.). The performance monitoring MSRs listed in Table 35-30 are shared between logical processors in the same core, but are replicated for each core.

### Table 35-30. MSRs Unique to Intel® Xeon® Processor 7100 Series

| Register Address | | Register Name Fields and Flags | Model Availability | Shared/ Unique | Bit Description |

| 107D3H | | MSR_EMON_L3_CTR_CTL7 | 6 | Shared | **FSB Event Control and Counter Register (R/W)** |

## 35.16 MSRS IN INTEL® CORE™ SOLO AND INTEL® CORE™ DUO PROCESSORS

Model-specific registers (MSRs) for Intel Core Solo, Intel Core Duo processors, and Dual-core Intel Xeon processor LV are listed in Table 35-31. The column "Shared/Unique" applies to Intel Core Duo processor. "Unique" means each processor core has a separate MSR, or a bit field in an MSR governs only a core independently. "Shared" means the MSR or the bit field in an MSR address governs the operation of both processor cores.

Table 35-31. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| 0H | 0 | P5_MC_ADDR | Unique | See Section 35.19, "MSRs in Pentium Processors," and see Table 35-2. |
| 1H | 1 | P5_MC_TYPE | Unique | See Section 35.19, "MSRs in Pentium Processors," and see Table 35-2. |
| 6H | 6 | IA32_MONITOR_FILTER_SIZE | Unique | See Section 8.10.5, "Monitor/Mwait Address Range Determination," and see Table 35-2. |
| 10H | 16 | IA32_TIME_STAMP_COUNTER | Unique | See Section 17.13, "Time-Stamp Counter," and see Table 35-2. |
| 17H | 23 | IA32_PLATFORM_ID | Shared | **Platform ID (R)**<br>See Table 35-2.<br>The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load. |
| 1BH | 27 | IA32_APIC_BASE | Unique | See Section 10.4.4, "Local APIC Status and Location," and see Table 35-2. |
| 2AH | 42 | MSR_EBL_CR_POWERON | Shared | **Processor Hard Power-On Configuration (R/W)**<br>Enables and disables processor features; (R) indicates current processor configuration. |
| | | 0 | | Reserved. |

### Table 35-31. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV

| Register Address | | Register Name | Shared/ Unique | Bit Description |
|---|---|---|---|---|
| Hex | Dec | | | |
| | | 1 | | **Data Error Checking Enable (R/W)**<br>1 = Enabled; 0 = Disabled<br>Note: Not all processor implements R/W. |

## 35.17 MSRS IN THE PENTIUM M PROCESSOR

Model-specific registers (MSRs) for the Pentium M processor are similar to those described in Section 35.18 for P6 family processors. The following table describes new MSRs and MSRs whose behavior has changed on the Pentium M processor.

**Table 35-32. MSRs in Pentium M Processors**

| Register Address | | Register Name | Bit Description |
|---|---|---|---|
| Hex | Dec | | |
| 0H | 0 | P5_MC_ADDR | See Section 35.19, "MSRs in Pentium Processors." |
| 1H | 1 | P5_MC_TYPE | See Section 35.19, "MSRs in Pentium Processors." |
| 10H | 16 | IA32_TIME_STAMP_COUNTER | See Section 17.13, "Time-Stamp Counter," and see Table 35-2. |
| 17H | 23 | IA32_PLATFORM_ID | **Platform ID (R)**<br>See Table 35-2.<br>The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load. |
| 2AH | 42 | MSR_EBL_CR_POWERON | **Processor Hard Power-On Configuration**<br>**(R/W)** Enables and disables processor features.<br>**(R)** Indicates current processor configuration. |
| | | 0 | Reserved. |
| | | 1 | **Data Error Checking Enable (R)**<br>0 = Disabled<br>Always 0 on the Pentium M processor. |
| | | 2 | **Response Error Checking Enable (R)**<br>0 = Disabled<br>Always 0 on the Pentium M processor. |
| | | 3 | **MCERR# Drive Enable (R)**<br>0 = Disabled<br>Always 0 on the Pentium M processor. |

Table 35-32. MSRs in Pentium M Processors (Contd.)

| Register Address | | Register Name | Bit Description |
|---|---|---|---|
| Hex | Dec | | |
| | | 4 | **Address Parity Enable (R)**<br>0 = Disabled<br>Always 0 on the Pentium M processor. |
| | | 6:5 | Reserved. |
| | | 7 | **BINIT# Driver Enable (R)**<br>1 = Enabled; 0 = Disabled<br>Always 0 on the Pentium M processor. |
| | | 8 | **Output Tri-state Enabled (R/O)**<br>1 = Enabled; 0 = Disabled |
| | | 9 | **Execute BIST (R/O)**<br>1 = Enabled; 0 = Disabled |
| | | 10 | **MCERR# Observation Enabled (R/O)**<br>1 = Enabled; 0 = Disabled<br>Always 0 on the Pentium M processor. |
| | | 11 | Reserved. |
| | | 12 | **BINIT# Observation Enabled (R/O)**<br>1 = Enabled; 0 = Disabled<br>Always 0 on the Pentium M processor. |
| | | 13 | Reserved. |
| | | 14 | **1 MByte Power on Reset Vector (R/O)**<br>1 = 1 MByte; 0 = 4 GBytes<br>Always 0 on the Pentium M processor. |
| | | 15 | Reserved. |
| | | 17:16 | **APIC Cluster ID (R/O)**<br>Always 00B on the Pentium M processor. |
| | | 18 | **System Bus Frequency (R/O)**<br>0 = 100 MHz<br>1 = Reserved<br>Always 0 on the Pentium M processor. |
| | | 19 | Reserved. |
| | | 21: 20 | **Symmetric Arbitration ID (R/O)**<br>Always 00B on the Pentium M processor. |
| | | 26:22 | Clock Frequency Ratio (R/O) |
| 40H | 64 | MSR_LASTBRANCH_0 | **Last Branch Record 0 (R/W)**<br>One of 8 last branch record registers on the last branch record stack: bits 31-0 hold the 'from' address and bits 63-32 hold the to address.<br>See also:<br>▪ Last Branch Record Stack TOS at 1C9H<br>▪ Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)" |

Table 35-32. MSRs in Pentium M Processors (Contd.)

| Register Address | | Register Name | Bit Description |
|---|---|---|---|
| Hex | Dec | | |
| 41H | 65 | MSR_LASTBRANCH_1 | **Last Branch Record 1 (R/W)**<br>See description of MSR_LASTBRANCH_0. |
| 42H | 66 | MSR_LASTBRANCH_2 | **Last Branch Record 2 (R/W)**<br>See description of MSR_LASTBRANCH_0. |
| 43H | 67 | MSR_LASTBRANCH_3 | **Last Branch Record 3 (R/W)**<br>See description of MSR_LASTBRANCH_0. |
| 44H | 68 | MSR_LASTBRANCH_4 | **Last Branch Record 4 (R/W)**<br>See description of MSR_LASTBRANCH_0. |
| 45H | 69 | MSR_LASTBRANCH_5 | **Last Branch Record 5 (R/W)**<br>See description of MSR_LASTBRANCH_0. |
| 46H | 70 | MSR_LASTBRANCH_6 | **Last Branch Record 6 (R/W)**<br>See description of MSR_LASTBRANCH_0. |
| 47H | 71 | MSR_LASTBRANCH_7 | **Last Branch Record 7 (R/W)**<br>See description of MSR_LASTBRANCH_0. |
| 119H | 281 | MSR_BBL_CR_CTL | |
| | | 63:0 | Reserved. |
| 11EH | 281 | MSR_BBL_CR_CTL3 | |
| | | 0 | **L2 Hardware Enabled (RO)**<br>1 = If the L2 is hardware-enabled<br>0 = Indicates if the L2 is hardware-disabled |
| | | 4:1 | Reserved. |
| | | 5 | **ECC Check Enable (RO)**<br>This bit enables ECC checking on the cache data bus. ECC is always generated on write cycles.<br>0 = Disabled (default)<br>1 = Enabled<br>For the Pentium M processor, ECC checking on the cache data bus is always enabled. |
| | | 7:6 | Reserved. |
| | | 8 | **L2 Enabled (R/W)**<br>1 = L2 cache has been initialized<br>0 = Disabled (default)<br>Until this bit is set the processor will not respond to the WBINVD instruction or the assertion of the FLUSH# input. |
| | | 22:9 | Reserved. |
| | | 23 | **L2 Not Present (RO)**<br>0 = L2 Present<br>1 = L2 Not Present |
| | | 63:24 | Reserved. |
| 179H | 377 | IA32_MCG_CAP | |

**Table 35-32. MSRs in Pentium M Processors (Contd.)**

| Register Address | | Register Name | Bit Description |
|---|---|---|---|
| Hex | Dec | | |
| | | 7:0 | **Count (RO)**<br>Indicates the number of hardware unit error reporting banks available in the processor. |
| | | 8 | **IA32_MCG_CTL Present (RO)**<br>1 = Indicates that the processor implements the MSR_MCG_CTL register found at MSR 17BH.<br>0 = Not supported. |
| | | 63:9 | Reserved. |
| 17AH | 378 | IA32_MCG_STATUS | |
| | | 0 | **RIPV**<br>When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If this bit is cleared, the program cannot be reliably restarted. |
| | | 1 | **EIPV**<br>When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error. |
| | | 2 | **MCIP**<br>When set, this bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception. |
| | | 63:3 | Reserved. |
| 198H | 408 | IA32_PERF_STATUS | See Table 35-2. |
| 199H | 409 | IA32_PERF_CTL | See Table 35-2. |
| 19AH | 410 | IA32_CLOCK_MODULATION | **Clock Modulation (R/W).**<br>See Table 35-2.<br>See Section 14.7.3, "Software Controlled Clock Modulation." |
| 19BH | 411 | IA32_THERM_INTERRUPT | **Thermal Interrupt Control (R/W)**<br>See Table 35-2.<br>See Section 14.7.2, "Thermal Monitor." |
| 19CH | 412 | IA32_THERM_STATUS | **Thermal Monitor Status (R/W)**<br>See Table 35-2.<br>See Section 14.7.2, "Thermal Monitor." |
| 19DH | 413 | MSR_THERM2_CTL | |
| | | 15:0 | Reserved. |

Table 35-32. MSRs in Pentium M Processors (Contd.)

| Register Address | | Register Name | Bit Description |
|---|---|---|---|
| Hex | Dec | | |
| | | 16 | **TM_SELECT (R/W)**<br>Mode of automatic thermal monitor:<br>0 = Thermal Monitor 1 (thermally-initiated on-die modulation of the stop-clock duty cycle)<br>1 = Thermal Monitor 2 (thermally-initiated frequency transitions)<br>If bit 3 of the IA32_MISC_ENABLE register is cleared, TM_SELECT has no effect. Neither TM1 nor TM2 will be enabled. |
| | | 63:16 | Reserved. |
| 1A0 | 416 | IA32_MISC_ENABLE | **Enable Miscellaneous Processor Features (R/W)**<br>Allows a variety of processor functions to be enabled and disabled. |
| | | 2:0 | Reserved. |
| | | 3 | **Automatic Thermal Control Circuit Enable (R/W)**<br>1 = Setting this bit enables the thermal control circuit (TCC) portion of the Intel Thermal Monitor feature. This allows processor clocks to be automatically modulated based on the processor's thermal sensor operation.<br>0 = Disabled (default).<br>The automatic thermal control circuit enable bit determines if the thermal control circuit (TCC) will be activated when the processor's internal thermal sensor determines the processor is about to exceed its maximum operating temperature.<br>When the TCC is activated and TM1 is enabled, the processors clocks will be forced to a 50% duty cycle. BIOS must enable this feature.<br>The bit should not be confused with the on-demand thermal control circuit enable bit. |
| | | 6:4 | Reserved. |
| | | 7 | **Performance Monitoring Available (R)**<br>1 = Performance monitoring enabled<br>0 = Performance monitoring disabled |
| | | 9:8 | Reserved. |
| | | 10 | **FERR# Multiplexing Enable (R/W)**<br>1 = FERR# asserted by the processor to indicate a pending break event within the processor<br>0 = Indicates compatible FERR# signaling behavior<br>This bit must be set to 1 to support XAPIC interrupt model usage. |
| | | | **Branch Trace Storage Unavailable (RO)**<br>1 = Processor doesn't support branch trace storage (BTS)<br>0 = BTS is supported |
| | | 12 | **Precise Event Based Sampling Unavailable (RO)**<br>1 = Processor does not support precise event-based sampling (PEBS);<br>0 = PEBS is supported.<br>The Pentium M processor does not support PEBS. |
| | | 15:13 | Reserved. |

**Table 35-32. MSRs in Pentium M Processors (Contd.)**

| Register Address | | Register Name | Bit Description |
|---|---|---|---|
| Hex | Dec | | |
| | | 16 | **Enhanced Intel SpeedStep Technology Enable (R/W)**<br>1 = Enhanced Intel SpeedStep Technology enabled.<br>On the Pentium M processor, this bit may be configured to be read-only. |
| | | 22:17 | Reserved. |
| | | 23 | **xTPR Message Disable (R/W)**<br>When set to 1, xTPR messages are disabled. xTPR messages are optional messages that allow the processor to inform the chipset of its priority. The default is processor specific. |
| | | 63:24 | Reserved. |
| 1C9H | 457 | MSR_LASTBRANCH_TOS | **Last Branch Record Stack TOS (R/W)**<br>Contains an index (bits 0-3) that points to the MSR containing the most recent branch record. See also:<br>▪ MSR_LASTBRANCH_0_FROM_IP (at 40H)<br>▪ Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)" |
| 1D9H | 473 | MSR_DEBUGCTLB | **Debug Control (R/W)**<br>Controls how several debug features are used. Bit definitions are discussed in the referenced section.<br>See Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)." |
| 1DDH | 477 | MSR_LER_TO_LIP | **Last Exception Record To Linear IP (R)**<br>This area contains a pointer to the target of the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.<br>See Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)" and Section 17.12.2, "Last Branch and Last Exception MSRs." |
| 1DEH | 478 | MSR_LER_FROM_LIP | **Last Exception Record From Linear IP (R)**<br>Contains a pointer to the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.<br>See Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)" and Section 17.12.2, "Last Branch and Last Exception MSRs." |
| 2FFH | 767 | IA32_MTRR_DEF_TYPE | **Default Memory Types (R/W)**<br>Sets the memory type for the regions of physical memory that are not mapped by the MTRRs.<br>See Section 11.11.2.1, "IA32_MTRR_DEF_TYPE MSR." |
| 400H | 1024 | IA32_MC0_CTL | See Section 15.3.2.1, "IA32_MCi_CTL MSRs." |
| 401H | 1025 | IA32_MC0_STATUS | See Section 15.3.2.2, "IA32_MCi_STATUS MSRS." |
| 402H | 1026 | IA32_MC0_ADDR | See Section 14.3.2.3., "IA32_MCi_ADDR MSRs".<br>The IA32_MC0_ADDR register is either not implemented or contains no address if the ADDRV flag in the IA32_MC0_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception. |

Table 35-32. MSRs in Pentium M Processors (Contd.)

| Register Address | | Register Name | Bit Description |

## 35.18 MSRS IN THE P6 FAMILY PROCESSORS

The following MSRs are defined for the P6 family processors. The MSRs in this table that are shaded are available only in the Pentium II and Pentium III processors. Beginning with the Pentium 4 processor, some of the MSRs in this list have been designated as "architectural" and have had their names changed. See Table 35-2 for a list of the architectural MSRs.

## Table 35-33. MSRs in the P6 Family Processors

| Register Address | | Register Name | Bit Description |
|---|---|---|---|
| Hex | Dec | | |
| 0H | 0 | P5_MC_ADDR | See Section 35.19, "MSRs in Pentium Processors." |
| 1H | 1 | P5_MC_TYPE | See Section 35.19, "MSRs in Pentium Processors." |
| 10H | 16 | TSC | See Section 17.13, "Time-Stamp Counter." |
| 17H | 23 | IA32_PLATFORM_ID | **Platform ID (R)**<br>The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load. |
| | | 49:0 | Reserved. |
| | | 52:50 | **Platform Id (R)**<br>Contains information concerning the intended platform for the processor.<br>52 51 50<br>0 0 0 Processor Flag 0<br>0 0 1 Processor Flag 1<br>0 1 0 Processor Flag 2<br>0 1 1 Processor Flag 3<br>1 0 0 Processor Flag 4<br>1 0 1 Processor Flag 5<br>1 1 0 Processor Flag 6<br>1 1 1 Processor Flag 7 |
| | | 56:53 | L2 Cache Latency Read. |
| | | 59:57 | Reserved. |
| | | 60 | Clock Frequency Ratio Read. |
| | | 63:61 | Reserved. |
| 1BH | 27 | APIC_BASE | Section 10.4.4, "Local APIC Status and Location." |
| | | 7:0 | Reserved. |
| | | 8 | **Boot Strap Processor indicator Bit**<br>1 = BSP |
| | | 10:9 | Reserved. |
| | | 11 | **APIC Global Enable Bit - Permanent till reset**<br>1 = Enabled<br>0 = Disabled |
| | | 31:12 | APIC Base Address. |
| | | 63:32 | Reserved. |
| 2AH | 42 | EBL_CR_POWERON | **Processor Hard Power-On Configuration**<br>**(R/W)** Enables and disables processor features;<br>**(R)** indicates current processor configuration. |
| | | 0 | Reserved.[1] |
| | | 1 | **Data Error Checking Enable (R/W)**<br>1 = Enabled<br>0 = Disabled |
| | | 2 | **Response Error Checking Enable FRCERR Observation Enable (R/W)**<br>1 = Enabled<br>0 = Disabled |

Table 35-33. MSRs in the P6 Family Processors (Contd.)

| 413H | 1043 | MC3_MISC | Defined in MCA architecture but not implemented in the P6 family processors. |

NOTES

1. Bit 0 of this register has been redefined several times, and is no longer used in P6 family processors.
2. The processor number feature may be disabled by setting bit 21 of the BBL_CR_CTL MSR (model-specific register address 119h) to "1". Once set, bit 21 of the BBL_CR_CTL may not be cleared. This bit is write-once. The processor number feature will be disabled until the processor is reset.
3. The Pentium III processor will prevent FSB frequency overclocking with a new shutdown mechanism. If the FSB frequency selected is greater than the internal FSB frequency the processor will shutdown. If the FSB selected is less than the internal FSB frequency the BIOS may choose to use bit 11 to implement its own shutdown policy.

## 35.19 MSRS IN PENTIUM PROCESSORS

The following MSRs are defined for the Pentium processors. The P5_MC_ADDR, P5_MC_TYPE, and TSC MSRs (named IA32_P5_MC_ADDR, IA32_P5_MC_TYPE, and IA32_TIME_STAMP_COUNTER in the Pentium 4 processor) are architectural; that is, code that accesses these registers will run on Pentium 4 and P6 family processors without generating exceptions (see Section 35.1, "Architectural MSRs"). The CESR, CTR0, and CTR1 MSRs are unique to Pentium processors; code that accesses these registers will generate exceptions on Pentium 4 and P6 family processors.

Table 35-34. MSRs in the Pentium Processor

| Register Address | | Register Name | Bit Description |

# CHAPTER 36
# INTEL® PROCESSOR TRACE

## 36.1 OVERVIEW

Intel® Processor Trace (**Intel PT**) is an extension of Intel® Architecture that captures information about software execution using dedicated hardware facilities that cause only minimal performance perturbation to the software being traced. This information is collected in **data packets**. The first implementation of Intel PT offers **control flow tracing**, which includes in these packets timing and program flow information (e.g. branch targets, branch taken/not taken indications) and program-induced mode related information (e.g. Intel TSX state transitions, CR3 changes). These packets may be buffered internally before being sent to the memory subsystem or other output mechanism available in the platform. Debug software can process the trace data and reconstruct the program flow.

### 36.1.1 Features and Capabilities

Intel PT's control flow trace generates a variety of packets that, when combined with the binaries of a program by a post-processing tool, can be used to produce an exact execution trace. The packets record flow information such as instruction pointers (IP), indirect branch targets, and directions of conditional branches within contiguous code regions (basic blocks).

In addition, the packets record other contextual, timing, and bookkeeping information that enables both functional and performance debugging of applications. Intel PT has several control and filtering capabilities available to customize the tracing information collected and to append other processor state and timing information to enable debugging. For example, there are modes that allow packets to be filtered based on the current privilege level (CPL) or the value of CR3.

Configuration of the packet generation and filtering capabilities are programmed via a set of MSRs. The MSRs generally follow the naming convention of IA32_RTIT_*.

#### 36.1.1.1 Packet Summary

After a tracing tool has enabled and configured the appropriate MSRs, the processor will collect and generate trace information in the following types of packets (for more details on the packets, see Section 36.4):

- Packet Stream Boundary (**PSB**) packets: PSB packets act as 'heartbeats' that are generated at regular intervals (e.g., every 4K trace packet bytes). These packets allow the packet decoder to find the packet boundaries within the output data stream; a PSB packet should be the first packet that a decoder looks for when beginning to decode a trace.
- Taken Not-Taken (**TNT**) packets: TNT packets track the "direction" of direct conditional branches (taken or not taken).
- Target IP (**TIP**) packets: TIP packets record the target IP of indirect branches, exceptions, interrupts, and other branches or events. These packets can contain the IP, although that IP value may be compressed by eliminating upper bytes that match the last IP. There are various types of TIP packets; they are covered in more detail in Section 36.4.2.2.
- Flow Update Packets (**FUP**): FUPs provide the source IP addresses for asynchronous events (interrupt and exceptions), as well as other cases where the source address cannot be determined from the binary.
- Paging Information Packet (**PIP**): PIPs record modifications made to the CR3 register. This information, along with information from the operating system on the CR3 value of each process, allows the debugger to attribute linear addresses to their correct application source.
- Time-Stamp Counter (**TSC**) packets: TSC packets aid in tracking wall-clock time, and contain some portion of the software-visible time-stamp counter.
- **MODE** packets: These packets provide the decoder with important processor execution information so that it can properly interpret the binary and trace log. MODE packets have a variety of formats that indicate details such as the execution mode (16-bit, 32-bit, or 64-bit).

- Core Bus Ratio (**CBR**) packets: CBR packets contain the core:bus clock ratio.
- Overflow (**OVF**) packets: OVF packets are sent when the processor experiences an internal buffer overflow, resulting in packets being dropped. This packet notifies the decoder of the loss and can help the decoder to respond to this situation.

## 36.2 INTEL® PROCESSOR TRACE OPERATIONAL MODEL

This section describes the overall Intel Processor Trace mechanism and the essential concepts relevant to how it operates.

### 36.2.1 Change of Flow Instruction (COFI) Tracing

A basic program block is a section of code where no jumps or branches occur. The instruction pointers (IPs) in this block of code need not be traced, as the processor will execute them from start to end without redirecting code flow. Instructions such as branches, and events such as exceptions or interrupts, can change the program flow. These instructions and events that change program flow are called Change of Flow Instructions (COFI). There are three categories of COFI:

- Direct transfer COFI.
- Indirect transfer COFI.
- Far transfer COFI.

The following subsections describe the COFI events that result in trace packet generation. Table 36-1 lists branch instruction by COFI types. For detailed description of specific instructions, see *Intel® 64 and IA-32 Architectures Software Developer's Manual*.

**Table 36-1. COFI Type for Branch Instructions**

| COFI Type | Instructions |
|---|---|
| Conditional Branch | JA, JAE, JB, JBE, JC, JCXZ< JECXZ, JRCXZ, JE, JG, JGE, JL, JLE, JNA, JNAE, JNB, JNBE, JNC, JNE, JNG, JNGE, JNL, JNLE, JNO, JNP, JNS, JNZ, JO, JP, JPE, JPO, JS, JZ, LOOP, LOOPE, LOOPNE, LOOPNZ, LOOPZ |
| Unconditional Direct Branch | JMP (E9 xx, EB xx), CALL (E8 xx) |
| Indirect Branch | JMP (FF /4), CALL (FF /2) |
| Near Ret | RET (C3, C2 xx) |
| Far Transfers | INT3, INTn, INTO, IRET, IRETD, IRETQ, JMP (EA xx, REX.W? FF /5), CALL (9A xx, FF /3), RET (CB, CA xx), SYSCALL, SYSRET, SYSENTER, SYSEXIT |

#### 36.2.1.1 Direct Transfer COFI

Direct Transfer COFI are relative branches. This means that their target is an IP whose offset from the current IP is embedded in the instruction bytes. It is not necessary to indicate target of these instructions in the trace output since it can be obtained through the source disassembly. Conditional branches need to indicate only whether the branch is taken or not. Unconditional branches do not need any recording in the trace output. There are two sub-categories:

- **Conditional Branch (Jcc, J*CXZ) and LOOP**

  To track this type of instruction, the processor encodes a single bit (taken or not taken — TNT) to indicate the program flow after the instruction.

  Jcc, J*CXZ, and LOOP can be traced with TNT bits. To improve the trace packet output efficiency, the processor will compact several TNT bits into a single packet.

- **Unconditional Direct Jumps**

  There is no trace output for direct unconditional jumps (like JMP near relative or CALL near relative) since they can be directly inferred from the application assembly. Direct unconditional jumps do not generate a TNT bit or a Target IP packet.

#### 36.2.1.2 Indirect Transfer COFI

Indirect transfer instructions involve updating the IP from a register or memory location. Since the register or memory contents can vary at any time during execution, there is no way to know the target of the indirect transfer until the register or memory contents are read. As a result, the disassembled code is not sufficient to determine the target of this type of COFI. Therefore, tracing hardware must send out the destination IP in the trace packet for debug software to determine the target address of the COFI. Note that this IP may be a linear or effective address (see Section 36.3.1.1)

An indirect transfer instruction generates a Target IP Packet (TIP) that contains the target address of the branch. There are two sub-categories:

- **Near JMP Indirect and Near Call Indirect**

  As previously mentioned, the target of an indirect COFI resides in the contents of either a register or memory location. Therefore, the processor must generate a packet that includes this target address to allow the decoder to determine the program flow.

- **Near RET**

  When a CALL instruction executes, it pushes onto the stack the address of the next instruction following the CALL. Upon completion of the call procedure, the RET instruction is often used to pop the return address off of the call stack and redirect code flow back to the instruction following the CALL.

  A RET instruction simply transfers program flow to the address it popped off the stack. Because a called procedure may change the return address on the stack before executing the RET instruction, debug software can be misled if it assumes that code flow will return to the instruction following the last CALL. Therefore, even for near RET, a Target IP Packet may be sent.

  — **RET Compression**

    A special case is applied if the target of the RET is consistent with what would be expected from tracking the CALL stack. If it is assured that the decoder has seen the corresponding CALL (with "corresponding" defined as the CALL with matching stack depth), and the RET target is the instruction after that CALL, the RET target may be "compressed". In this case, only a single TNT bit of "taken" is generated instead of a Target IP Packet. To ensure that the decoder will not be confused in cases of RET compression, only RETs that correspond to CALLs which have been seen since the last PSB packet may be compressed. For details, see "Indirect Transfer Compression for Returns (RET)" in Section 36.4.2.2.

#### 36.2.1.3 Far Transfer COFI

All operations that change the instruction pointer and are not near jumps are "far transfers". This includes exceptions, interrupts, traps, TSX aborts, and instructions that do far transfers.

All far transfers will produce a Target IP (TIP) packet, which provides the destination IP address. For those far transfers that cannot be inferred from the binary source (e.g., asynchronous events such as exceptions and interrupts), the TIP will be preceded by a Flow Update packet (FUP), which provides the source IP address at which the event was taken. Table 36-19 indicates exactly which IP will be included in the FUP generated by a far transfer.

See the packet generation scenarios (Section 36.4.3) for more details on which packets are generated on each variety of far transfer.

### 36.2.2 Trace Filtering

Intel Processor Trace provides filtering capabilities, by which the debug/profile tool can control what code is traced.

#### 36.2.2.1 Filtering by Current Privilege Level (CPL)

Intel PT provides the ability to configure a logical processor to generate trace packets only when CPL = 0, when CPL > 0, or regardless of CPL.

CPL filtering ensures that no IPs or other architectural state information associated with the filtered CPL can be seen in the log. For example, if the processor is configured to trace only when CPL > 0, and software executes SYSCALL (changing the CPL to 0), the destination IP of the SYSCALL will be suppressed from the generated packet (see the discussion of TIP.PGD in Section 36.4.2.5).

It should be noted that CPL is always 0 in real-address mode and that CPL is always 3 in virtual-8086 mode. To trace code in these modes, filtering should be configured accordingly.

When software is executing in a non-enabled CPL, ContextEn is cleared. See Section 36.2.3.1 for details.

#### 36.2.2.2 Filtering by CR3

Intel PT supports a CR3-filtering mechanism by which control-flow packet generation can be enabled or disabled based on the value of CR3. A debugger can use CR3 filtering to trace only a single application without context switching the state of the RTIT MSRs. To the reconstruction of traces from software with multiple threads, debug software may wish to context-switch the state of the RTIT MSRs (if the operating system does not provide context-switch support) to separate the output for the different threads (see Section 36.3.4, "Context Switch Consideration").

To trace for only a single CR3 value, software can write that value to the IA32_RTIT_CR3_MATCH MSR, and set IA32_RTIT_CTL.CR3Filter. When CR3 value does not match IA32_RTIT_CR3_MATCH and IA32_RTIT_CTL.CR3Filter is 1, ContextEn is forced to 0, and control-flow packets will not be generated. Some other packets can be generated when ContextEn is 0; see Section 36.2.3.3 for details. When CR3 does match IA32_RTIT_CR3_MATCH (or when IA32_RTIT_CTL.CR3Filter is 0), CR3 filtering does not force ContextEn to 0 (although it could be 0 due to other filters or modes).

CR3 matches IA32_RTIT_CR3_MATCH if the two registers are identical for bits 63:5; the lower 5 bits of CR3 and IA32_RTIT_CR3_MATCH are ignored. CR3 filtering is independent of the value of CR0.PG.

When CR3 filtering is in use, PIP packets may still be seen in the log if the processor is configured to trace when CPL = 0 (IA32_RTIT_CTL.OS = 1). If not, no PIP packets will be seen.

### 36.2.3 Packet Generation Enable Controls

Intel Processor Trace includes a variety of controls that determine whether a packet is generated. In general, most packets are sent only if Packet Enable (**PacketEn**) is set. PacketEn is an internal state maintained in hardware in response to software configurable enable controls, PacketEn is not visible to software directly. The relationship of PacketEn to the software-visible controls in the configuration MSRs is described in this section.

#### 36.2.3.1 Packet Enable (PacketEn)

When PacketEn is set, the processor is in the mode that Intel PT is monitoring and all packets can be generated to log what is being executed. PacketEn is composed of other states according to this relationship:

```
PacketEn = TriggerEn AND ContextEn
```

These constituent controls are detailed in the following subsections.

PacketEn ultimately determines when the processor is tracing. When PacketEn is set, all control flow packets are enabled. When PacketEn is clear, no control flow packets are generated, though other packets (timing and bookkeeping packets) may still be sent. See Section 36.2.4 for details of PacketEn and packet generation.

#### 36.2.3.2 Trigger Enable (TriggerEn)

Trigger Enable (**TriggerEn**) is the primary indicator that trace packet generation is active. TriggerEn is set when IA32_RTIT_CTL.TraceEn is set, and cleared by any of the following conditions:

- TraceEn is cleared by software,
- IA32_RTIT_STATUS.Error is set due to an internal error (see Section 36.3.7).

The processor may not update ContextEn when TriggerEn=0. The processor guarantees that ContextEn is correctly evaluated only when TriggerEn = 1.

Software can discover the current TriggerEn value by reading the IA32_RTIT_STATUS.TriggerEn bit. When TriggerEn is clear, tracing is inactive and no packets are generated.

#### 36.2.3.3 Context Enable (ContextEn)

Context Enable (**ContextEn**) indicates whether the processor is in the state or mode that software configured hardware to trace. For example, if execution with CPL = 0 code is not being traced (IA32_RTIT_CTL.OS = 0), then ContextEn will be 0 when the processor is in CPL0.

Software can discover the current ContextEn value by reading the IA32_RTIT_STATUS.ContextEn bit. ContextEn is defined as follows:

```
ContextEn = !((IA32_RTIT_CTL.OS = 0 AND CPL = 0) OR
(IA32_RTIT_CTL.USER = 0 AND CPL > 0) OR
(IA32_RTIT_CTL.CR3Filter = 1 AND IA32_RTIT_CR3_MATCH does not match CR3)
```

If the clearing of ContextEn causes PacketEn to be cleared, a Packet Generation Disable (TIP.PGD) packet is generated, but its IP payload is suppressed. If the setting of ContextEn causes PacketEn to be set, a Packet Generation Enable (TIP.PGE) packet is generated.

When ContextEn is 0, control flow packets TNT, FUP, TIP, PIP, MODE) are not generated, and no LIPs are exposed. For details of which packets are generated only when ContextEn is set, see Section 36.4.1.

The processor does not update ContextEn when TriggerEn = 0.

### 36.2.4 Packet Output to Memory

Trace output is written to memory in a collection of variable-sized regions of physical memory. These regions are linked together by tables of pointers to those regions, referred to as Table of Physical Addresses (**ToPA**). The trace output stores bypass the caches and the TLBs, but are not serializing. This is intended to minimize the performance impact of the output.

#### 36.2.4.1 Table of Physical Addresses (ToPA)

The ToPA mechanism uses a linked list of tables; see Figure 36-1 for an illustrative example. Each entry in the table contains some attribute bits, a pointer to an output region, and the size of the region. The last entry in the table may hold a pointer to the next table. This pointer can either point to the top of the current table (for circular array) or to the base of another table. The table size is not fixed, since the link to the next table can exist at any entry.

The processor treats the various output regions referenced by the ToPA table(s) as a unified buffer. This means that a single packet may span the boundary between one output region and the next.

The ToPA mechanism is controlled by three values maintained by the processor:

- **proc_trace_table_base.**
  This is the physical address of the base of the current ToPA table. When tracing is enabled, the processor loads this value from the IA32_RTIT_OUTPUT_BASE MSR. While tracing is enabled, the processor updates the IA32_RTIT_OUTPUT_BASE MSR with changes to proc_trace_table_base, but these updates may not be synchronous to software execution. When tracing is disabled, the processor ensures that the MSR contains the latest value of proc_trace_table_base.
- **proc_trace_table_offset.**
  This indicates the entry of the current table that is currently in use. (This entry contains the address of the current output region.) When tracing is enabled, the processor loads this value from bits 31:7 (MaskOrTableOffset) of the IA32_RTIT_OUTPUT_MASK_PTRS. While tracing is enabled, the processor updates IA32_RTIT_OUTPUT_MASK_PTRS.MaskOrTableOffset with changes to proc_trace_table_offset, but these updates may not be synchronous to software execution. When tracing is disabled, the processor ensures that the MSR contains the latest value of proc_trace_table_offset.
- **proc_trace_output_offset.**
  This a pointer into the current output region and indicates the location of the next write. When tracing is enabled, the processor loads this value from bits 63:32 (OutputOffset) of the IA32_RTIT_OUTPUT_MASK_PTRS. While tracing is enabled, the processor updates IA32_RTIT_OUTPUT_MASK_PTRS.OutputOffset with changes to proc_trace_output_offset, but these updates may not be synchronous to software execution. When tracing is disabled, the processor ensures that the MSR contains the latest value of proc_trace_output_offset.

Figure 36-1 provides an illustration (not to scale) of the table and associated pointers.

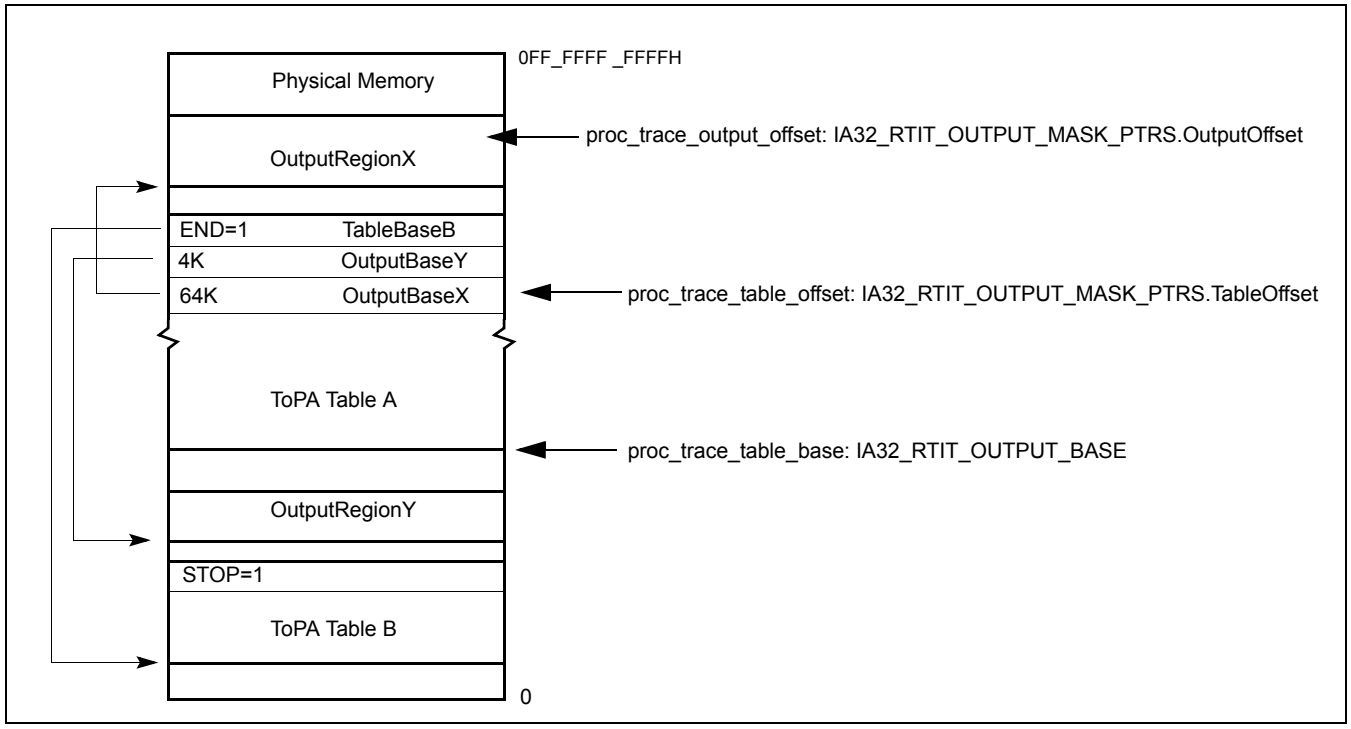

**Figure 36-1. ToPA Memory Illustration**

With the ToPA mechanism, the processor writes packets to the current output region (identified by proc_trace_table_base and the proc_trace_table_offset). The offset within that region to which the next byte will be written is identified by proc_trace_output_offset. When that region is filled with packet output (thus proc_trace_output_offset = RegionSize–1), proc_trace_table_offset is moved to the next ToPA entry, proc_trace_output_offset is set to 0, and packet writes begin filling the new output region specified by proc_trace_table_offset.

Eventually, the regions represented by all entries in the table may become full, and the final entry of the table is reached. An entry can be identified as the final entry because it has either the END or STOP attribute. The END attribute indicates that the address in the entry does not point to another output region, but rather to another ToPA table. The STOP attribute indicates that tracing will be disabled once the corresponding region is filled. See Section 36.2.4.1 for details on STOP.

When an END entry is reached, the processor loads proc_trace_table_base with the base address held in this END entry, thereby moving the current table pointer to this new table. The proc_trace_table_offset is reset to 0, as is the proc_trace_output_offset, and packet writes will resume at the base address indicated in the first entry.

If the table has no STOP or END entry, and trace-packet generation remains enabled, eventually the maximum table size will be reached (proc_trace_table_offset = FFFFFFFFH). In this case, the proc_trace_table_offset and proc_trace_output_offset are reset to 0 (wrapping back to the beginning of the current table) once the last output region is filled.

It is important to note that processor updates to the IA32_RTIT_OUTPUT_BASE and IA32_RTIT_OUTPUT_MASK_PTRS MSRs are asynchronous to instruction execution. Thus, reads of these MSRs while Intel PT is enabled may return stale values. Like all IA32_RTIT_* MSRs, the values of these MSRs should not be trusted or saved unless trace packet generation is first disabled by clearing IA32_RTIT_CTL.TraceEn. This ensures that all internally buffered packet data are written to memory. When TraceEn is 0, the values of the IA32_RTIT_OUTPUT_BASE and IA32_RTIT_OUTPUT_MASK_PTRS MSR are up to date and do not change. A store fence or serializing instruction following the clearing of TraceEn may be required to ensure that trace output data are globally observed.[1]

The processor may cache internally any number of entries from the current table or from tables that it references (directly or indirectly). If tracing is enabled, the processor may ignore or delay detection of modifications to these

tables. To ensure that table changes are detected by the processor in a predictable manner, software should clear TraceEn before modifying the current table (or tables that it references) and only then re-enable packet generation.

As packets are written out to memory, each store derives its physical address as follows:

```
trace_store_phys_addr = Base address from current ToPA table entry +
proc_trace_output_offset
```

There is no guarantee that a packet will be written to memory after some fixed number of cycles after a packet-producing instruction executes. The only way to assure that all packets generated can be seen in memory is to clear TraceEn; doing so ensures that all buffered packets are written to memory.

### Single Output Region ToPA Implementation

The first processor generation to implement Intel PT supports only ToPA configurations with a single ToPA entry followed by an END entry that points back to the first entry (creating one circular output buffer). Such processors enumerate CPUID.(EAX=14H,ECX=0):ECX.MENTRY[bit 1] = 0 and CPUID.(EAX=14H,ECX=0):ECX.TOPAOUT[bit 0] = 1.

### ToPA Table Entry Format

The format of ToPA table entries is shown in Figure 36-2. The size of the address field is determined by the processor's physical-address width (MAXPHYADDR) in bits, as reported in CPUID.80000008H:EAX[7:0].

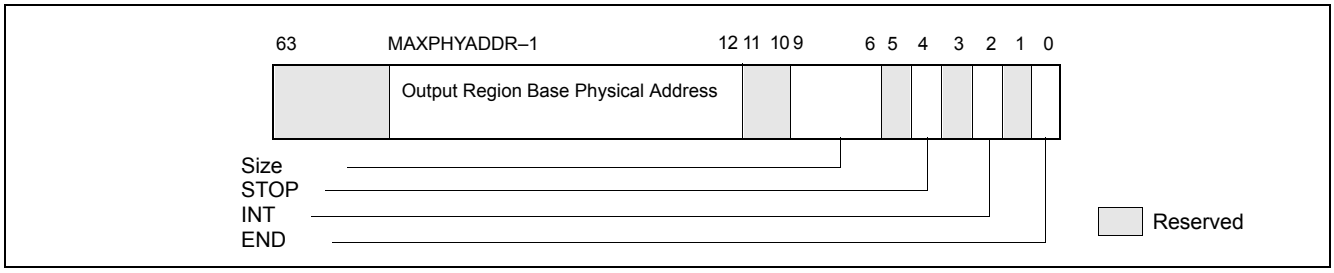

**Figure 36-2. Layout of ToPA Table Entry**

Table 36-2 describes the details of the ToPA table entry fields. If reserved bits are set to 1, an error is signaled.

**Table 36-2. ToPA Table Entry Fields**

| ToPA Entry Field | Description |
|---|---|
| Output Region Base Physical Address | If END=0, this is the base physical address of the output region specified by this entry. Note that all regions must be aligned based on their size. Thus a 2M region must have bits 20:12 clear. If the region is not properly aligned, an operational error will be signaled when the entry is reached.<br>If END=1, this is the 4K-aligned base physical address of the next ToPA table (which may be the base of the current table, or the first table in the linked list if a circular buffer is desired). If the processor supports only a single ToPA output region (see above), this address must be the value currently in the IA32_RTIT_OUTPUT_BASE MSR. |
| Size | Indicates the size of the associated output region. Encodings are:<br>0: 4K, 1: 8K, 2: 16K, 3: 32K, 4: 64K, 5: 128K, 6: 256K, 7: 512K,<br>8: 1M, 9: 2M, 10: 4M, 11: 8M, 12: 16M, 13: 32M, 14: 64M, 15: 128M<br>This field is ignored if END=1. |
| STOP | When the output region indicated by this entry is filled, software should disable packet generation. This will be accomplished by setting IA32_RTIT_STATUS.Stopped, which clears TriggerEn. This bit must be 0 if END=1; otherwise it is treated as reserved bit violation (see ToPA Errors) |

1. Although WRMSR is a serializing instruction, the execution of WRMSR that forces packet writes by clearing TraceEn does not itself cause these writes to be globally observed.

**Table 36-2. ToPA Table Entry Fields**

| ToPA Entry Field | Description |
|---|---|
| INT | When the output region indicated by this entry is filled, signal Perfmon LVT interrupt.<br>Note that if both INT and STOP are set in the same entry, the STOP will happen before the INT. Thus the interrupt handler should expect that the IA32_RTIT_STATUS.Stopped bit will be set, and will need to be reset before tracing can be resumed.<br>This bit must be 0 if END=1; otherwise it is treated as reserved bit violation (see ToPA Errors) |
| END | If set, indicates that this is an END entry, and thus the address field points to a table base rather than an output region base.<br>If END=1, INT and STOP must be set to 0; otherwise it is treated as reserved bit violation (see ToPA Errors). The Size field is ignored in this case.<br>If the processor supports only a single ToPA output region (see above), END must be 1 in any ToPA entry other than the first (whenever proc_trace_table_offset differs from the value in the IA32_RTIT_OUTPUT_BASE MSR. |

### ToPA STOP

Each ToPA entry has a STOP bit. If this bit is set, the processor will set the IA32_RTIT_STATUS.Stopped bit when the corresponding trace output region is filled. This will clear TriggerEn and thereby cease packet generation. See Section 36.2.5.3 for details on IA32_RTIT_STATUS.Stopped. This sequence is known as "ToPA Stop"

No TIP.PGD packet will be seen in the output when the ToPA stop occurs, since the disable happens only when the region is already full. When this occurs, any packets remaining in internal buffers are lost and cannot be recovered.

When ToPA stop occurs, the IA32_RTIT_OUTPUT_BASE MSR will hold the base address of the table whose entry had STOP=1. IA32_RTIT_OUTPUT_MASK_PTRS.MaskOrTableOffset will hold the index value for that entry, and the IA32_RTIT_OUTPUT_MASK_PTRS.OutputOffset should be set to the size of the region.

### ToPA PMI

Each ToPA entry has an INT bit. If this bit is set, the processor will signal a performance-monitoring interrupt (PMI) when the corresponding trace output region is filled. This interrupt is not precise, and it is thus likely that writes to the next region will occur by the time the interrupt is taken.

A usage model envisioned for this attribute is for software to copy output data to external memory before the output region is full.

The following steps should be taken to configure this interrupt:

1. Enable PMI via the LVT Performance Monitor register (at MMIO offset 340H in xAPIC mode; via MSR 834H in x2APIC mode). See *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3B* for more details on this register. For ToPA PMI, set all fields to 0, save for the interrupt vector, which can be selected by software.
2. Set the interrupt flag by executing STI.
3. Set the INT bit in the ToPA entry of interest and enable packet generation, using the ToPA output option. Thus, TraceEn=ToPA=1 in the IA32_RTIT_CTL MSR.

Once the INT region has been filled with packet output data, the interrupt will be signaled. This PMI can be distinguished from others by checking bit 55 (Trace_ToPA_PMI) of the IA32_PERF_GLOBAL_STATUS MSR (MSR 38EH). Once the ToPA PMI handler has serviced the relevant buffer, writing 1 to IA32_PERF_GLOBAL_OVF_CTL.[bit 55] will clear IA32_PERF_GLOBAL_STATUS.Trace_ToPA_PMI.

Note that no "freezing" takes place with the ToPA PMI. Thus, packet generation is not frozen, and the interrupt handler will be traced (though filtering can prevent this). Further, the setting of IA32_DEBUGCTL.Freeze_Perfmon_on_PMI is ignored and performance counters are not frozen by a ToPA PMI.

Assuming the PMI handler wishes to read any buffered packets for persistent output, software should first disable packet generation by clearing TraceEn. This ensures that all buffered packets are written to memory and avoids tracing of the PMI handler. The configuration MSRs can then be used to determine where tracing has stopped. If packet generation is disabled by the handler, it should then be manually re-enabled before the IRET if continued tracing is desired.

### ToPA PMI and Single Output Region ToPA Implementation

A processor that supports only a single ToPA output region implementation (such that only one output region is supported; see above) will attempt to signal a ToPA PMI interrupt before the output wraps and overwrites the top of the buffer. To support this functionality, the PMI handler should disable packet generation as soon as possible.

Due to PMI skid, it is possible, in rare cases, that the wrap will have occurred before the PMI is delivered. Software can avoid this by setting the STOP bit in the ToPA entry (see Table 36-2); this will disable tracing once the region is filled, and no wrap will occur. This approach has the downside of disabling packet generation so that some of the instructions that led up to the PMI will not be traced. If the PMI skid is significant enough to cause the region to fill and tracing to be disabled, the PMI handler will need to clear the IA32_RTIT_STATUS.Stopped indication before tracing can resume.

### ToPA Errors

When a malformed ToPA entry is found, an **operation error** results (see Section 36.3.7). A malformed entry can be any of the following:

1. **ToPA entry reserved bit violation**.
   This describes cases where a bit marked as reserved in Section 36.2.4.1 above is set to 1.
2. **ToPA alignment violation**.
   This includes cases where illegal ToPA entry base address bits are set to 1:
   a. ToPA table base address is not 4KB-aligned. The table base can be from a WRMSR to IA32_RTIT_OUTPUT_BASE, or from a ToPA entry with END=1.
   b. ToPA entry base address is not aligned to the ToPA entry size (e.g., a 2MB region with base address[20:12] not equal to 0).
   c. ToPA entry base address sets upper physical address bits not supported by the processor.
3. **Illegal ToPA Output Offset** (if IA32_RTIT_STATUS.Stopped=0).
   IA32_RTIT_OUTPUT_MASK_PTRS.OutputOffset is greater than or equal to the size of the current ToPA output region size.
4. **ToPA rules violations**.
   These are similar to ToPA entry reserved bit violations; they are cases when a ToPA entry is encountered with illegal field combinations. They include the following:
   a. Setting the STOP or INT bit on an entry with END=1.
   b. Setting the END bit in entry 0 of a ToPA table.
   c. On processors that support only a single ToPA entry (see above), two additional illegal settings apply:
      i) ToPA table entry 1 with END=0.
      ii) ToPA table entry 1 with base address not matching the table base.

In all cases, the error will be logged by setting IA32_RTIT_STATUS.Error, thereby disabling tracing when the problematic ToPA entry is reached (when proc_trace_table_offset points to the entry containing the error). Any packet bytes that are internally buffered when the error is detected may be lost.

Note that operational errors may also be signaled due to attempts to access restricted memory. See Section 36.2.4.2 for details.

A tracing software have a range of flexibility using ToPA to manage the interaction of Intel PT with application buffers, see Section 36.5.

## 36.2.4.2 Restricted Memory Access

Packet output cannot be directed to any regions of memory that are restricted by the platform. In particular, all memory accesses on behalf of packet output are checked against the SMRR regions. If there is any overlap with these regions, trace data collection will not function properly. Exact processor behavior is implementation-dependent; Table 36-3 summarizes several scenarios.

Table 36-3. Behavior on Restricted Memory Access

| Scenario | Description |
|---|---|
| ToPA output region overlaps with SMRR | Stores to the restricted memory region will be dropped, and that packet data will be lost. Any attempt to read from that restricted region will return all 1s. The processor also may signal an error (Section 36.3.7) and disable tracing when the output pointer reaches the restricted region. If packet generation remains enabled, then packet output may continue once stores are no longer directed to restricted memory (on wrap, or if the output region is larger than the restricted memory region). |
| ToPA table overlaps with SMRR | The processor will signal an error (Section 36.3.7) and disable tracing when the ToPA read pointer (IA32_RTIT_OUTPUT_BASE + (proc_trace_table_offset « 3)) enters the restricted region. |

It should also be noted that packet output should not be routed to the 4KB APIC MMIO region, as defined by the IA32_APIC_BASE MSR. For details about the APIC, refer to *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*. No error is signaled for this case.

#### Modifications to Restricted Memory Regions

It is recommended that software disable packet generation before modifying the SMRRs to change the scope of the SMRR regions. This is because the processor reserves the right to cache any number of ToPA table entries internally, after checking them against restricted memory ranges. Once cached, the entries will not be checked again, meaning one could potentially route packet output to a newly restricted region. Software can ensure that any cached entries are written to memory by clearing IA32_RTIT_CTL.TraceEn.

## 36.2.5 Enabling and Configuration MSRs

### 36.2.5.1 General Considerations

Trace packet generation is enabled and configured by a collection of model-specific registers (MSRs), which are detailed below. Some notes on the configuration MSR behavior:

- If Intel Processor Trace is not supported by the processor (see Section 36.3.1), RDMSR or WRMSR of the IA32_RTIT_* MSRs will cause #GP.
- A WRMSR to any of these configuration MSRs that begins and ends with IA32_RTIT_CTL.TraceEn set will #GP fault. Packet generation must be disabled before the configuration MSRs can be changed.

  Note: Software may write the same value back to IA32_RTIT_CTL without #GP, even if TraceEn=1.
- All configuration MSRs for Intel PT are duplicated per logical processor
- For each configuration MSR, any MSR write that attempts to change bits marked reserved, or utilize encodings marked reserved, will cause a #GP fault.

### 36.2.5.2 IA32_RTIT_CTL MSR

IA32_RTIT_CTL, at address 570H, is the primary enable and control MSR for trace packet generation. Bit positions are listed in Table 36-4.

Table 36-4. IA32_RTIT_CTL MSR

| Position | Bit Name | At Reset | Bit Description |
|---|---|---|---|
| 0 | TraceEn | 0 | If 1, enables tracing; else tracing is disabled if 0<br>When this bit transitions from 1 to 0, all buffered packets are written to their output destination.<br>When this bit transitions from 0 to 1, a series of packets may be generated. This may include PSB, along with associated status packets (see Section 36.4.2.3), or may include only a TSC and CBR packet (see Section 36.4.2.9 and Section 36.4.2.10).<br>If changing this bit changes PacketEN, a TIP.PGE or TIP.PGD will be generated. In the TIP.PGE case, a MODE packet will precede it, see Section 36.4.2.8. |

Table 36-4. IA32_RTIT_CTL MSR

| Position | Bit Name | At Reset | Bit Description |
|---|---|---|---|
| 1 | Reserved | 0 | Must be 0 |
| 2 | OS | 0 | 0: Packet generation is disabled when CPL = 0<br>1: Packet generation may be enabled when CPL = 0 |
| 3 | User | 0 | 0: Packet generation is disabled when CPL > 0<br>1: Packet generation may be enabled when CPL > 0 |
| 6:4 | Reserved | 0 | Must be 0 |
| 7 | CR3Filter | 0 | 0: Disables CR3 filtering<br>1: Enables CR3 filtering |
| 8 | ToPA | 0 | 1: ToPA output scheme enabled (see Section 36.2.4.1)<br>WRMSR to IA32_RTIT_CTL that sets TraceEn but clears this bit causes #GP. |
| 9 | Reserved | 0 | Must be 0 |
| 10 | TSCEn | 0 | 0: Disable TSC packets<br>1: Enable TSC packets (see Section 36.4.2.10) |
| 11 | DisRETC | 0 | 0: Enable RET compression<br>1: Disable RET compression (see Section 36.2.1.2) |
| 12 | Reserved | 0 | Must be 0 |
| 13 | Reserved | 0 | WRMSR to IA32_RTIT_CTL that sets TraceEn but clears this bit causes #GP. |
| 63:14 | Reserved | 0 | Must be 0 |

## Enabling Packet Generation

When TraceEn transitions from 0 to 1, packet generation is enabled, and a series of packets may be generated. These packets help ensure that the decoder is aware of the state of the processor when the trace begins, and that it can keep track of any timing or state changes that may have occurred while packet generation was disabled. This may be a full PSB+ (see Section 36.4.2.12), or it may be a TSC (see Section 36.4.2.10) followed by CBR (see Section 36.4.2.9), if those packets are enabled.

In addition to the packets above, once PacketEn (Section 36.2.3.1) transitions from 0 to 1 (which may happen immediately, depending on filtering settings), a MODE.Exec packet (Section 36.4.2.8) followed by a TIP.PGE packet (Section 36.4.2.3) will be generated. The TIP.PGE and MODE packets could come before or after the PSB packet, the TSC packet, or the CBR packet.

When TraceEn is set, the processor may read ToPA entries from memory and cache them internally. For this reason, software should disable packet generation before making modifications to the ToPA tables (or changing the configuration of restricted memory regions). See Section 36.4.3 for more details of packets that may be generated with modifications to TraceEn.

## Disabling Packet Generation

A WRMSR that clears TraceEn causes any buffered packets to be written to memory. After software disables packet generation by clearing TraceEn, all packets have been written to memory and that the output MSRs (IA32_RTIT_OUTPUT_BASE and IA32_RTIT_OUTPUT_MASK_PTRS) have stable values. (As noted earlier a store fence or serializing instruction may be required to ensure that trace output data are globally observed.[1]) No special packets are generated by disabling packet generation, though a TIP.PGD may result if PacketEn=1 at the time of disable.

1. Although WRMSR is a serializing instruction, the execution of WRMSR that forces packet writes by clearing TraceEn does not itself cause them to be globally observed.

#### Other Writes to IA32_RTIT_CTL

Any attempt to modify IA32_RTIT_CTL while TraceEn is set will result in a general-protection fault (#GP) unless the same write also clears TraceEn. However, writes to IA32_RTIT_CTL that do not modify any bits will not cause a #GP, even if TraceEn remains set.

### 36.2.5.3 IA32_RTIT_STATUS MSR

The IA32_RTIT_STATUS MSR is readable and writable by software, but some bits (ContextEn, TriggerEn) are read-only and cannot be directly modified. The WRMSR instruction ignores these bits in the source operand (attempts to modify these bits are ignored and do not cause WRMSR to fault).

This MSR can only be written when IA32_RTIT_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP). The processor does not modify the value of this MSR while TraceEn is 0 (software can modify it with WRMSR).

**Table 36-5. IA32_RTIT_STATUS MSR**

| Position | Bit Name | At Reset | Bit Description |
|---|---|---|---|
| 0 | Reserved | 0 | Writes are ignored. |
| 1 | ContextEn | 0 | The processor sets this bit to indicate that tracing is allowed for the current context. See Section 36.2.3.3. Writes are ignored. |
| 2 | TriggerEn | 0 | The processor sets this bit to indicate that tracing is enabled. See Section 36.2.3.2. Writes are ignored. |
| 3 | Reserved | 0 | Must be 0. |
| 4 | Error | 0 | The processor sets this bit to indicate that an operational error has been encountered. When this bit is set, TriggerEn is cleared to 0 and packet generation is disabled. For details, see "ToPA Errors" in Section 36.2.4.1.<br>When TraceEn is cleared, software can write this bit. Once it is set, only software can clear it. It is not recommended that software ever set this bit, except in cases where it is restoring a prior saved state |
| 5 | Stopped | 0 | The processor sets this bit to indicate that a ToPA Stop condition has been encountered. When this bit is set, TriggerEn is cleared to 0 and packet generation is disabled. For details, see "ToPA STOP" in Section 36.2.4.1.<br>When TraceEn is cleared, software can write this bit. Once it is set, only software can clear it. It is not recommended that software ever set this bit, except in cases where it is restoring a prior saved state. |
| 63:6 | Reserved | 0 | Must be 0. |

### 36.2.5.4 IA32_RTIT_CR3_MATCH MSR

When IA32_RTIT_CTL.CR3Filter is 1, ContextEn is set on only if CR3 matches the IA32_RTIT_CR3_MATCH MSR. CR3 matches IA32_RTIT_CR3_MATCH if the two registers are identical for bits 63:5; the lower 5 bits of CR3 and IA32_RTIT_CR3_MATCH are not compared. For more details, see Section 36.2.2.2.

This MSR can be written only when IA32_RTIT_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP). IA32_RTIT_CR3_MATCH[4:0] are reserved and must be 0; an attempt to set those bits using WRMSR causes a #GP.

### 36.2.5.5 IA32_RTIT_OUTPUT_BASE MSR

This MSR is used to configure the output region of internally-buffered packets. The size of the address field is determined by the maximum physical address width (MAXPHYADDR), as reported by CPUID.80000008H:EAX[7:0].

The processor updates this MSR while when packet generation is enabled, and those updates are asynchronous to instruction execution. Therefore, the values in this MSR should be considered unreliable unless packet generation is disabled (IA32_RTIT_CTL.TraceEn = 0).

This MSR can be written only when IA32_RTIT_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP).

**Table 36-6. IA32_RTIT_OUTPUT_BASE MSR**

| Position | Bit Name | At Reset | Bit Description |
|---|---|---|---|
| 6:0 | Reserved | 0 | Must be 0. |
| MAXPHYADDR-1:7 | BasePhysAddr | 0 | The base physical address. How this address is used depends on the value of IA32_RTIT_CTL.ToPA:<br>0: This is the base physical address of a single, contiguous physical output region. This could be mapped to DRAM or to MMIO, depending on the value.<br>The base address should be aligned with the size of the region, such that none of the 1s in the mask value(Section 36.2.5.6) overlap with 1s in the base address. If the base is not aligned, an operational error will result (see Section 36.3.7).<br>1: The base physical address of the current ToPA table. The address must be 4K aligned. Writing an address in which bits 11:7 are non-zero will not cause a #GP, but an operational error will be signaled once TraceEn is set. See "ToPA Errors" in Section 36.2.4.1 as well as Section 36.3.7. |
| 63:MAXPHYADDR | Reserved | 0 | Must be 0. |

### 36.2.5.6 IA32_RTIT_OUTPUT_MASK_PTRS MSR

This MSR holds the pointers that indicate the ToPA entry that is currently in use and the offset into that entry's output region to which packets are being written. See Section 36.2.4.1 for details.

The processor updates this MSR while when packet generation is enabled, and those updates are asynchronous to instruction execution. Therefore, the values in this MSR should be considered unreliable unless packet generation is disabled (IA32_RTIT_CTL.TraceEn = 0).

This MSR can be written only when IA32_RTIT_CTL.TraceEn is 0; otherwise WRMSR causes a general-protection fault (#GP).

**Table 36-7. IA32_RTIT_OUTPUT_MASK_PTRS MSR**

| Position | Bit Name | At Reset | Bit Description |
|---|---|---|---|
| 6:0 | LowerMask | 7FH | Forced to 1, writes are ignored. |
| 31:7 | MaskOrTableOffset | 0 | This field holds bits 27:3 of the offset pointer into the current ToPA table. This value can be added to the IA32_RTIT_OUTPUT_BASE value to produce a pointer to the current ToPA table entry, which itself is a pointer to the current output region. In this scenario, the lower 7 reserved bits are ignored. This field supports tables up to 256 MBytes in size. |
| 63:32 | OutputOffset | 0 | This field holds bits 31:0 of the offset pointer into the current ToPA output region. This value will be added to the output region base field, found in the current ToPA table entry, to form the physical address at which the next byte of trace output data will be written.<br>This value must be less than the ToPA entry size, otherwise an operational error (Section 36.3.7) will be signaled when TraceEn is set. |

## 36.2.6 Interaction of Intel® Processor Trace and Other Processor Features

### 36.2.6.1 Intel® Transactional Synchronization Extensions (Intel® TSX)

The operation of Intel TSX is described in Chapter 14 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*. For tracing purpose, packet generation does not distinguish between hardware lock elision (HLE) and restricted transactional memory (RTM), but speculative execution does have impacts on the trace output. Specifically, packets are generated as instructions complete, even for instructions in a transactional region that is later aborted. For this reason, debugging software will need indication of the beginning and end of a transactional region; this will allow software to understand when instructions are part of a transactional region and whether that region has been committed.

To enable this, TSX information is included in a MODE packet leaf. The mode bits in the leaf are:

- **InTX**: Set to 1 on an TSX transaction begin, and cleared on transaction commit or abort.
- **TXAbort**: Set to 1 only when InTX transitions from 1 to 0 on an abort. Cleared otherwise.

This MODE packet will be sent each time the transaction status changes. See Table 36-8 for details.

**Table 36-8. TSX Packet Scenarios**

| TSX Event | Instruction | Packets |
|---|---|---|
| Transaction Begin | Either XBEGIN or XACQUIRE lock (the latter if executed transactionally) | MODE(TXAbort=0, InTX=1), FUP(CurrentIP). |
| Transaction Commit | Either XEND or XRELEASE lock, if transactional execution ends. This happens only on the outermost commit | MODE(TXAbort=0, InTX=0), FUP(CurrentIP) |
| Transaction Abort | XABORT or other transactional abort | MODE(TXAbort=1, InTX=0), FUP(CurrentIP), TIP(TargetIP) |
| Other | One of the following:<br>▪ Nested XBEGIN or XACQUIRE lock<br>▪ An outer XACQUIRE lock that doesn't begin a transaction (InTX not set)<br>▪ Non-outermost XEND or XRELEASE lock | None. No change to TSX mode bits for these cases |

The CurrentIP listed above is the IP of the associated instruction. The TargetIP is the IP of the next instruction to be executed; for HLE, this is the XACQUIRE lock; for RTM, this is the fallback handler.

Intel PT stores are non-transactional, and thus packet writes are not rolled back on TSX abort.

### 36.2.6.2 System Management Mode (SMM)

SMM code has special privileges that non-SMM code does not have. Intel Processor Trace can be used to trace SMM code, but special care is taken to ensure that SMM handler context is not exposed in any non-SMM trace collection and that packet output from non-SMM code cannot be written into memory space protected by SMRR.

SMM is entered via a system management interrupt (SMI). SMI delivery saves the value of IA32_RTIT_CTL.TraceEn into SMRAM and then clears it, thereby disabling packet generation.

The saving and clearing of IA32_RTIT_CTL.TraceEn ensures two things:

1. All internally buffered packet data is written to memory before entering SMM (see Section 36.2.5.2).
2. Packet generation ceases before entering SMM, so any tracing that was configured outside SMM does not continue into SMM. No SMM instruction pointers or other state will be exposed in the non-SMM trace.

When the RSM instruction is executed to return from SMM, the TraceEn value that was saved by SMI delivery is restored, allowing tracing to be resumed. As is done any time packet generation is enabled, ContextEn is re-evaluated, based on the values of CPL, CR3, etc., established by RSM.

Like other interrupts, delivery of an SMI produces a FUP containing the IP of the next instruction to execute. By toggling TraceEn, SMI and RSM can produce TIP.PGD and TIP.PGE packets, indicating that tracing was disabled or re-enabled. Table 36-9 shows an example of the packets that can be expected when an SMI occurs while the processor is tracing (PacketEn = 1) software outside SMM.

**Table 36-9. SMI/RSM Packets When Trace Packet Generation is Enabled Outside SMM**

| Code Flow | Packets |
|---|---|
| ... Non-SMM Code<br>1004H ADD %ebx, %eax ; #SMI arrives | ... Non-SMM Packets<br>FUP(1006H), TIP.PGD() |
| 38000H JMP bar ; Enters SMM handler<br>... SMM code<br>38500H RSM | <br><br>TIP.PGE(1006H) |

Table 36-9. SMI/RSM Packets When Trace Packet Generation is Enabled Outside SMM

| Code Flow | Packets |
|---|---|
| 1006H SUB %ebx, %ebp<br>... More Non-SMM Code | ... More non-SMM packets |

Note that TraceEn must be cleared before executing RSM, otherwise it will cause a shutdown. Further, on processors that restrict use of Intel PT with LBRs (see Section 36.3.1.2), any RSM that results in enabling of both will cause a shutdown.

#### 36.2.6.3 Virtual-Machine Extensions (VMX)

Initial implementations of Intel Processor Trace do not support tracing in VMX operation. Execution of the VMXON instruction clears TraceEn. An attempt to set IA32_RTIT_CTL.TraceEn using WRMSR in VMX operation causes a general-protection fault (#GP).

This implies that these implementations do not support Intel PT is not supported in a virtualized environment. Future implementations may relax this restriction.

#### 36.2.6.4 SENTER/ENTERACCS and ACM

GETSEC[SENTER] and GETSEC[ENTERACCS] instructions clear TraceEn, and it is not restored when those instruction complete. SENTER also causes TraceEn to be cleared on other logical processors when they rendezvous and enter the SENTER sleep state. In these two cases, the disabling of packet generation is not guaranteed to write buffered packets to memory. Some packets may be dropped.

When executing an authenticated code module (ACM), packet generation is silently disabled during ACRAM setup. TraceEn will be cleared, but no TIP.PGD packet is generated. After completion of the module, the TraceEn value will be restored. There will be no TIP.PGE packet, but timing packets, like TSC and CBR, may be produced.

## 36.3 CONFIGURATION AND PROGRAMMING GUIDELINE

### 36.3.1 Detection of Intel Processor Trace and Capability Enumeration

Processor support for Intel Processor Trace is indicated by CPUID.(EAX=07H,ECX=0H):EBX[bit 25] = 1. CPUID function 14H is dedicated to enumerate the resource and capability of processors that report CPUID.(EAX=07H,ECX=0H):EBX[bit 25] = 1. Different processor generations may have architecturally-defined variation in capabilities. Table 36-10 describes details of the enumerable capabilities that software must use across generations of processors that support Intel Processor Trace.

Table 36-10. CPUID Leaf 14H Enumeration of Intel Processor Trace Capabilities

| CPUID.(EAX=14H,ECX=0) | | Name | Description Behavior |
|---|---|---|---|
| Register | Bits | | |
| EAX | 31:0 | Maximum valid sub-leaf Index | Specifies the index of the maximum valid sub-leaf for this CPUID leaf |
| EBX | 0 | CR3 Filtering Support | 1: Indicates that IA32_RTIT_CTL.CR3Filter can be set to 1, and that IA32_RTIT_CR3_MATCH MSR can be accessed. See Section 36.2.5.<br>0: Indicates that writes that set IA32_RTIT_CTL.CR3Filter to 1, or any access to IA32_RTIT_CR3_MATCH, will #GP fault. |
| | 31:1 | Reserved | |

Table 36-10. CPUID Leaf 14H Enumeration of Intel Processor Trace Capabilities

| CPUID.(EAX=14H,ECX=0) | | Name | Description Behavior |
|---|---|---|---|
| Register | Bits | | |
| ECX | 0 | ToPA Output Supported | 1: Tracing can be enabled with IA32_RTIT_CTL.ToPA = 1, hence utilizing the ToPA output scheme (Section 36.2.4.1) IA32_RTIT_OUTPUT_BASE and IA32_RTIT_OUTPUT_MASK_PTRS MSRs can be accessed.<br>0: Enabling tracing (TraceEn=1) with IA32_RTIT_CTL.ToPA=1 or IA32_RTIT_OUTPUT_MASK_PTRS. MSRs will #GP fault. |
| | 1 | ToPA Tables Allow Multiple Output Entries | 1: ToPA tables can hold any number of output entries, up to the maximum allowed by the MaskOrTableOffset field of IA32_RTIT_OUTPUT_MASK_PTRS.<br>0: ToPA tables can hold only one output entry, which must be followed by an END=1 entry which points back to the base of the table.<br>Further, ToPA PMIs will be delivered before the region is filled. See ToPA PMI in Section 36.2.4.1.<br>If there is more than one output entry before the END entry, or if the END entry has the wrong base address, an operational error will be signaled (see "ToPA Errors" in Section 36.2.4.1). |
| | 30:2 | Reserved | |
| | 31 | IP Payloads are LIP | 1: Generated packets which contain IP payloads have LIP values, which include the CS base component.<br>0: Generated packets which contain IP payloads have RIP values, which are the offset from CS base. |
| EDX | 31:0 | Reserved | |

### 36.3.1.1 Packet Decoding of RIP versus LIP

FUP, TIP, TIP.PGE, and TIP.PGE packets can contain an IP payload. On some processor generations, this payload will be an effective address (RIP), while on others this will be a linear address (LIP). In the former case, the payload is the offset from the current CS base address, while in the latter it is the sum of the offset and the CS base address. Which IP type is in use is indicated by enumeration (see Table 36-10).

For software that executes while the CS base address is 0 (including all software executing in 64-bit mode), the difference is indistinguishable. A trace decoder must account for cases, where the CS base address is not 0 and the distinction can be seen.

### 36.3.1.2 Model Specific Capability Restrictions

Some processor generations impose the following restrictions that prevent use of LBRs, BTS, BTM, or LERs when software has enabled tracing with Intel Processor Trace:

- If packet generation is enabled (IA32_RTIT_CTL.TraceEn = 1), any attempt to enable LBRs, LERs, BTS, or BTM (setting IA32_DEBUG_CTL.LBR =1 or IA32_DEBUG_CTL.TR = 1) will cause a general-protection fault (#GP). Further, any read or write of LBRs or LERs will cause a #GP. Enabling packet generation clears the LBRs, LERs, and the LBR TOS pointer.
- If LBR, BTS, or BTM is enabled, any attempt to enable trace packet generation will cause a #GP.
- A RSM that attempts to set both TraceEn and IA32_DEBUGCTL.LBR or IA32_DEBUGCTL.TR will go to shutdown.

For processor with CPUID DisplayFamily_DisplayModel signature of 06_3DH and 06_4AH, the use of Intel PT and LBRs are mutually exclusive.

### 36.3.2 Enabling and Configuration of Trace Packet Generation

To configure trace packets, enable packet generation, and capture packets, software starts with using CPUID instruction to detect its feature flag, CPUID.(EAX=07H,ECX=0H):EBX[bit 25] = 1; followed by enumerating the capabilities described in Section 36.3.1.

Based on the capability queried from Section 36.3.1, software must configure a number of model-specific registers. This section describes programming considerations related to those MSRs.

#### 36.3.2.1 Enabling Packet Generation

When configuration and enabling packet generation, the IA32_RTIT_CTL MSR should be written last, since writes to the other configuration MSRs cause a general-protection fault (#GP) if TraceEn = 1. If a prior trace collection context is not being restored, then software should first clear IA32_RTIT_STATUS. This is important since the Stopped, and Error fields are writable; clearing the MSR clears any values that may have persisted from prior trace packet collection contexts. See Section 36.2.5.2 for details of packets generated by setting TraceEn to 1.

If setting TraceEn to 1 causes an operational error (see Section 36.3.7), there may be a delay after the WRMSR completes before the error is signaled in the IA32_RTIT_STATUS MSR.

While packet generation is enabled, the values of some configuration MSRs (e.g., IA32_RTIT_STATUS and IA32_RTIT_OUTPUT_*) are transient, and reads may return values that are out of date. Only after packet generation is disabled (by clearing TraceEn) do reads of these MSRs return reliable values.

#### 36.3.2.2 Disabling Packet Generation

After disabling packet generation by clearing IA32_RTIT_CTL, it is advisable to read the IA32_RTIT_STATUS MSR (Section 36.2.5.3):

- If the Error bit is set, an operational error was encountered, and the trace is most likely compromised. Software should check the source of the error (by examining the output MSR values), correct the source of the problem, and then attempt to gather the trace again. For details on operational errors, see Section 36.3.7. Software should clear IA32_RTIT_STATUS.Error before re-enabling packet generation.
- If the Stopped bit is set, software execution encountered the ToPA Stop condition (see "ToPA STOP" in Section 36.2.4.1) before packet generation was disabled.

### 36.3.3 Forcing Packet Output to Be Written to Memory

Packets are first buffered internally and then written to memory asynchronously. To collect packet output for post-processing, a collector needs first to ensure that all internally buffered packets have been written to memory. Software can ensure this by stopping packet generation by clearing IA32_RTIT_CTL.TraceEn (see "Disabling Packet Generation" in Section 36.2.5.2).

When this operations complete, the IA32_RTIT_OUTPUT_* MSR values can be read to discover where the trace ended.

### 36.3.4 Context Switch Consideration

To facilitate construction of instruction execution traces at the granularity of a software process or thread context, software can save and restore the states of the trace configuration MSRs across the process or thread context switch boundary. The principle is the same as saving and restoring the typical architectural processor states across context switches.

The configuration can be saved and restored through a sequence of WRMSR and RDMSR instructions, respectively. To stop tracing and to ensure that all configuration MSRs contain stable values, software must clear IA32_RTIT_CTL.TraceEn before reading any other trace configuration MSRs. The recommended method for saving trace configuration context manually follows:

1. RDMSR IA32_RTIT_CTL, save value to memory
2. WRMSR IA32_RTIT_CTL with saved value from RDMSR above and TraceEn cleared

3. RDMSR all other configuration MSRs whose values had changed from previous saved value, save changed values to memory

When restoring the trace configuration context, IA32_RTIT_CTL should be restored last:

1. Read saved configuration MSR values, aside from IA32_RTIT_CTL, from memory, and restore them with WRMSR
2. Read saved IA32_RTIT_CTL value from memory, and restore with WRMSR.

### 36.3.5 Decoder Synchronization (PSB+)

The PSB packet (Section 36.4.2.12) serves as a synchronization point for a trace-packet decoder. It is a pattern in the trace log for which the decoder can quickly scan to align packet boundaries. No legal packet combination can result in such a byte sequence. As such, it serves as the starting point for packet decode. To decode a trace log properly, the decoder needs more than simply to be aligned: it needs to know some state and potentially some timing information as well.

When a PSB packet is generated, it is followed by a PSBEND packet (Section 36.4.2.13). One or more packets will be generated in between those two packets, and these inform the decoder of the current state of the processor. These packets, known collectively as PSB+, should be interpreted as "status only", since they do not imply any change of state at the time of the PSB, nor are they associated directly with any instruction or event. Thus, the normal binding and ordering rules that apply to these packets outside of PSB+ can be ignored when these packets are between a PSB and PSBEND. They inform the decoder of the state of the processor at the time of the PSB.

PSB+ can include:

- Timestamp (TSC), if IA32_RTIT_CTL.TSCEn=1
- Paging Info Packet (PIP), if ContextEn=1 and IA32_RTIT_CTL.OS=1
- Core Bus Ratio (CBR)
- MODE, including all supported MODE leaves, if ContextEn=1.
- Flow Update Packet (FUP), if ContextEn=1 The ordering of packets within PSB+ is not guaranteed to match on all processors implementations.

PSB is generated only when TriggerEn=1; hence PSB+ has the same dependencies.

Note that an overflow can occur during PSB+, and this could cause the PSBEND packet to be lost, potentially causing the decoder to treat all subsequent packets as "status only" until the next PSB. For this reason, the OVF packet should also be viewed as terminating PSB+.

### 36.3.6 Internal Buffer Overflow

In the rare circumstances when new packets need to be generated but the processor's dedicated internal buffers are all full, an "internal buffer overflow" occurs. On such an overflow packet generation ceases (as packets would need to enter the processor's internal buffer) until the overflow resolves. Once resolved packet generation resumes.

The buffer overflow condition might not be cleared until the buffer has been completely written to memory and is empty. When the buffer overflow is cleared naturally, an OVF packet (Section 36.4.2.11) is generated, and the internal state for compressing LIPs or RETs is cleared. This ensures that the next IP will not be compressed against a lost IP packet, and any RETs seen whose CALLs occurred before the overflow will not be compressed.

The OVF packet will be followed by a FUP or TIP.PGE, the payload of which will be the Current IP of the first instruction after the overflow is cleared. Between the OVF and following FUP or TIP.PGE, there may be other packets that are not dependent on ContextEn, even a full PSB+.

The IP in the FUP or TIP.PGE is that of the instruction at which packet generation resumes. Thus, on clearing of a buffer overflow, the decoder will know exactly where the processor is now executing, although it will not know the exact instruction where the buffer overflow occurred.

### 36.3.7 Operational Errors

Errors are detected as a result of packet output configuration problems, which can include output alignment issues, ToPA reserved bit violations, or overlapping packet output with restricted memory. See "ToPA Errors" in Section 36.2.4.1 for details on ToPA errors, and Section 36.2.4.2 for details on restricted memory errors. Operational errors are only detected and signaled when TraceEn=1.

When an operational error is detected, tracing is disabled and the error is logged. Specifically, IA32_RTIT_STATUS.Error is set, which will cause IA32_RTIT_STATUS.TriggerEn to be 0. This will disable generation of all packets. Some causes of operational errors may lead to packet bytes being dropped.

It should be noted that the timing of error detection may not be predictable. Errors are signaled when the processor encounters the problematic configuration. This could be as soon as packet generation is enabled but could also be later when the problematic entry or field needs to be used.

Once an error is signaled, software should disable packet generation by clearing TraceEn, diagnose and fix the error condition, and clear IA32_RTIT_STATUS.Error. At this point, packet generation can be re-enabled.

## 36.4 TRACE PACKETS AND DATA TYPES

This section details the data packets generated by Intel Processor Trace. It is useful for developers writing the interpretation code that will decode the data packets and apply it to the traced source code.

### 36.4.1 Packet Relationships and Ordering

This section introduces the concept of packet "binding", which involves determining the IP in a binary disassembly at which the change indicated by a given packet applies. Some packets have the associated IP as the payload (FUP, TIP), while for others the decoder need only search for the next instance of a particular instruction (or instructions) to bind the packet (TNT). However, in many cases, the decoder will need to consider the relationship between packets, and to use this packet context to determine how to bind the packet.

Section 36.4.2 below provides detailed descriptions of the packets, including how packets bind to IPs in the disassembly, to other packets, or to nothing at all. Many packets listed are simple to bind, because they are generated in only a few scenarios. Those that require more consideration are typically part of "compound packet events", such as interrupts, exceptions, and some instructions, where multiple packets are generated by a single operation (instruction or event). These compound packet events frequently begin with a FUP to indicate the source address (if it is not clear from the disassembly), and are concluded by a TIP or TIP.PGD packet that indicates the destination address (if one is provided). In this scenario, the FUP is said to be "coupled" with the TIP packet.

Other packets could be in between the coupled FUP and TIP packet. When the workload being traced changes CR3 or the processor's mode of execution, ia state update packet (i.e., PIP or MODE) is generated. A summary of compound packet events is provided in Table 36-11; see Section 36.4.2 for more per-packet details and Section 36.4.3 for more detailed packet generation examples.

**Table 36-11. Compound Packet Event Summary**

| Event Type | Beginning | Middle | End | Comment |
|---|---|---|---|---|
| Control-flow transfer | FUP or none | Any combination of PIP, MODE.Exec, or none | TIP or TIP.PGD | FUP only for asynchronous events. Order of middle packets may vary. PIP /MODE only if the operation modifies the state tracked by these respective packets |
| TSX Update | MODE.TSX, and (FUP or none) | None | TIP, TIP.PGD, or none | FUP<br>TIP/TIP.PGD only for TSX abort cases |
| Overflow | OVF | None | FUP or TIP.PGE | FUP if overflow resolves while ContextEn=1, else TIP.PGE. |

### 36.4.2 Packet Definitions

The following description of packet definitions are in tabular format. Figure 36-3 explains how to interpret them.

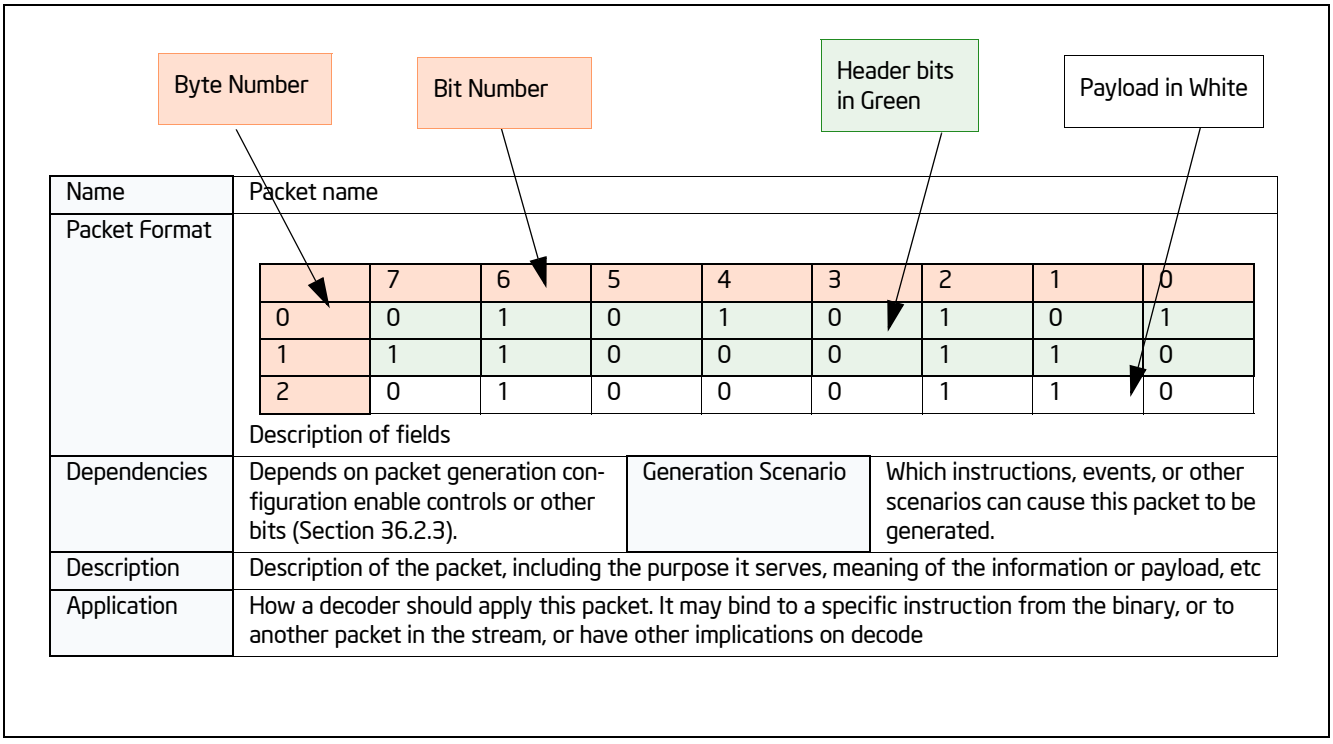

**Figure 36-3. Interpreting Tabular Definition of Packet Format**

### 36.4.2.1 Taken/Not-taken (TNT) Packet

**Table 36-12. TNT Packet Definition**

| Name | Taken/Not-taken (TNT) Packet |
|---|---|
| Packet Format | |

| | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
|---|---|---|---|---|---|---|---|---|---|
| 0 | 1 | $B_1$ | $B_2$ | $B_3$ | $B_4$ | $B_5$ | $B_6$ | 0 | Short TNT |

B1...BN represent the last N conditional branch or compressed RET (Section 36.4.2.2) results, such that B1 is oldest and BN is youngest. The short TNT packet can contain from 1 to 6 TNT bits. The long TNT packet can contain up from 1 to 47 TNT bits.

| | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
|---|---|---|---|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | Long TNT |
| 1 | 1 | 0 | 1 | 0 | 0 | 0 | 1 | 1 | |
| 2 | $B_{40}$ | $B_{41}$ | $B_{42}$ | $B_{43}$ | $B_{44}$ | $B_{45}$ | $B_{46}$ | $B_{47}$ | |
| 3 | $B_{32}$ | $B_{33}$ | $B_{34}$ | $B_{35}$ | $B_{36}$ | $B_{37}$ | $B_{38}$ | $B_{39}$ | |
| 4 | $B_{24}$ | $B_{25}$ | $B_{26}$ | $B_{27}$ | $B_{28}$ | $B_{29}$ | $B_{30}$ | $B_{31}$ | |
| 5 | $B_{16}$ | $B_{17}$ | $B_{18}$ | $B_{19}$ | $B_{20}$ | $B_{21}$ | $B_{22}$ | $B_{23}$ | |
| 6 | $B_8$ | $B_9$ | $B_{10}$ | $B_{11}$ | $B_{12}$ | $B_{13}$ | $B_{14}$ | $B_{15}$ | |
| 7 | 1 | $B_1$ | $B_2$ | $B_3$ | $B_4$ | $B_5$ | $B_6$ | $B_7$ | |

**Table 36-12. TNT Packet Definition**

<table>
<tr><td></td><td colspan="4">Irrespective of how many TNT bits is in a packet, the last valid TNT bit is followed by a trailing 1, or Stop bit, as shown above. If the TNT packet is not full (fewer than 6 TNT bits for the Short TNT, or fewer than 47 TNT bits for the Long TNT), the Stop bit moves up, and the trailing bits of the packet are filled with 0s. Examples of these “partial TNTs” are shown below.<br><br>
<table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td><td></td></tr>
<tr><td>0</td><td>0</td><td>0</td><td>1</td><td>$B_1$</td><td>$B_2$</td><td>$B_3$</td><td>$B_4$</td><td>0</td><td>Short TNT</td></tr>
</table>
<br>

</table></td></tr>
<tr><td>Dependencies</td><td>PacketEn</td><td>Generation Scenario</td><td colspan="3">Indirect branch (including uncompressed RET), far branch, interrupt, exception, INIT, SIPI, TSX abort.</td></tr>
<tr><td>Description</td><td colspan="5">Provides the target for some control flow transfers</td></tr>
<tr><td>Application</td><td colspan="5">Anytime a TIP is encountered, it indicates that control was transferred to the IP provided in the payload.</td></tr>
<tr><td></td><td colspan="5">The source of this control flow change, and hence the IP or instruction to which it binds, depends on the packets that precede the TIP. If a TIP is encountered and all preceding packets have already been bound, then the TIP will apply to the upcoming indirect branch, far branch, or RSM. However, if there was a preceding FUP that remains unbound, it will bind to the TIP. Here, the TIP provides the target of an asynchronous event or TSX abort that occurred at the IP given in the FUP payload. Note that there may be other packets, in addition to the FUP, which will bind to the TIP packet. See the packet application descriptions for other packets for details.</td></tr>
</table>

## IP Compression

The IP payload in a TIP. FUP, TIP.PGE, or TIP.PGD packet can vary in size, based on the mode of execution, and the use of IP compression. IP compression is an optional compression technique the processor may choose to employ to reduce bandwidth. With IP compression, the IP to be represented in the payload is compared with the last IP sent out, via any of FUP, TIP, TIP.PGE, or TIP.PGD. If that previous IP had the same upper (most significant) address bytes, those matching bytes may be suppressed in the current packet. The processor maintains an internal state of the "Last IP" that was encoded in trace packets, thus the decoder will need to keep track of the "Last IP" state in software, to match fidelity with packets generated by hardware.

The "IPBytes" field of the IP packets (FUP, TIP, TIP.PGE, TIP.PGD) serves to indicate how many bytes of payload are provided, and how the decoder should fill in any suppressed bytes. The algorithm for reconstructing the IP for a TIP/FUP packet is shown in the table below.

**Table 36-14. FUP/TIP IP Reconstruction**

<table>
<tr><td rowspan="2">IPBytes</td><td colspan="8">Uncompressed IP Value</td></tr>
<tr><td>63:56</td><td>55:48</td><td>47:40</td><td>39:32</td><td>31:24</td><td>23:16</td><td>15:8</td><td>7:0</td></tr>
<tr><td>000b</td><td colspan="8">None, IP is out of context</td></tr>
<tr><td>001b</td><td colspan="6">Last IP[63:16]</td><td colspan="2">IP Payload[15:0]</td></tr>
<tr><td>010b</td><td colspan="4">Last IP[63:32]</td><td colspan="4">IP Payload[31:0]</td></tr>
<tr><td>011b</td><td colspan="2">IP Payload[47] extended</td><td colspan="6">IP Payload[47:0]</td></tr>
<tr><td>100b</td><td colspan="8">Reserved</td></tr>
<tr><td>101b</td><td colspan="8">Reserved</td></tr>
<tr><td>110b</td><td colspan="8">Reserved</td></tr>
<tr><td>111b</td><td colspan="8">Reserved</td></tr>
</table>

Note that the processor-internal Last IP state may be cleared at any time, but is guaranteed to be cleared when a PSB is sent out. When the internal Last IP is cleared, this means that the next FUP/TIP/TIP.PGE/TIP.PGD will have no IP compression.

At times, "IPbytes" will have a value of 0. As shown above, this does not mean that the IP payload matches the full address of the last IP, but rather that the IP for this packet was suppressed. This is used for cases where the IP that applies to the packet is out of context. An example is the TIP.PGD sent on a SYSCALL, when tracing only USR code. In that case, no TargetIP will be included in the packet, since that would expose an instruction point at CPL = 0. When the IP payload is suppressed in this manner, Last IP is not cleared, and instead refers to the last IP packet with a non-zero IPBytes field.

#### Indirect Transfer Compression for Returns (RET)

In addition to IP compression, TIP packets for near return (RET) instructions can also be compressed. If the RET target matches the next IP of the corresponding CALL, then the TIP packet is unneeded, since the decoder can deduce the target IP by maintaining a CALL/RET stack of its own.

A CALL/RET stack can be maintained by the decoder by doing the following:

1. Allocate space to store 64 RET targets.
2. For near CALLs, push the Next IP onto the stack. Once the stack is full, new CALLs will force the oldest entry off the end of the stack, such that only the youngest 64 entries are stored. Note that this excludes zero-length CALLs, which are direct near CALLs with displacement zero (to the next IP). These CALLs typically don't have matching RETs.
3. For near RETs, pop the top (youngest) entry off the stack. This will be the target of the RET.

In cases where the RET is compressed, the target is guaranteed to match the value produced in 2) above. If the target is not compressed, a TIP packet will be generated with the RET target, which may differ from 2).

The hardware ensure that packets read by the decoder will always have seen the CALL that corresponds to any compressed RET. The processor will never compress a RET across a PSB, a buffer overflow, or scenario where PacketEn=0. This means that a RET whose corresponding CALL executed while PacketEn=0, or before the last PSB, etc., will not be compressed.

If the CALL/RET stack is manipulated or corrupted by software, and thereby causes a RET to transfer control to a target that is inconsistent with the CALL/RET stack, then the RET will not be compressed, and will produce a TIP packet. This can happen, for example, if software executes a PUSH instruction to push a target onto the stack, and a later RET uses this target.

When a RET is compressed, a Taken indication is added to the TNT buffer. Because it sends no TIP packet, it also does not update the internal Last IP value, and thus the decoder should treat it the same way. If the RET is not compressed, it will generate a TIP packet (just like when RET compression is disabled, via IA32_RTIT_CTL.DisRETC). For processors that employ deferred TIPs (Section 36.4.2.3), an uncompressed RET will not be deferred, and hence will force out any accumulated TNTs or TIPs. This serves to avoid ambiguity, and make clear to the decoder whether the near RET was compressed, and hence a bit in the in-progress TNT should be consumed, or uncompressed, in which case there will be no in-progress TNT and thus a TIP should be consumed.

Note that in the unlikely case that a RET executes in a different execution mode than the associated CALL, the decoder will need to model the same behavior with its CALL stack. For instance, if a CALL executes in 64-bit mode, a 64-bit IP value will be pushed onto the software stack. If the corresponding RET executes in 32-bit mode, then only the lower 32 target bits will be popped off of the stack, which may mean that the RET does not go to the CALL's Next IP. This is architecturally correct behavior, and this RET could be compressed, thus the decoder should match this behavior

### 36.4.2.3 Deferred TIPs

The processor may opt to defer sending out the TNT when TIPs are generated. Thus, rather than sending a partial TNT followed by a TIP, both packets will be deferred while the TNT accumulates more Jcc/RET results. Any number of TIP packets may be accumulated this way, such that only once the TNT is filled, or once another packet (e.g., FUP) is generated, the TNT will be sent, followed by all the deferred TIP packets, and finally terminated by the other packet(s) that forced out the TNT and TIP packets. Generation of many other packets (see list below) will force out the TNT and any accumulated TIP packets. This is an optional optimization in hardware to reduce the bandwidth consumption, and hence the performance impact, incurred by tracing.

**Table 36-15. TNT Examples with Deferred TIPs**

| Code Flow | Packets, Non-Deferred TIPS | Packets, Deferred TIPS |
|---|---|---|
| 0x1000 cmp %rcx, 0<br>0x1004 jnz Foo // not-taken<br>0x1008 jmp %rdx | TNT(0b0), TIP(0x1308) | |
| 0x1308 cmp %rcx, 1<br>0x130c jnz Bar // not-taken<br>0x1310 cmp %rcx, 2<br>0x1314 jnz Baz // taken<br>0x1500 cmp %eax, 7<br>0x1504 jg Exit // not-taken<br>0x1508 jmp %r15 | TNT(0b010), TIP(0x1100) | |
| 0x1100 cmp %rbx, 1<br>0x1104 jg Start // not-taken<br>0x1108 add %rcx, %eax<br>0x110c … // **an asynchronous Interrupt arrives**<br>INThandler:<br>0xcc00 pop %rdx | TNT(0b0), FUP(0x110c), TIP(0xcc00) | TNT(0b00100), TIP(0x1308), TIP(0x1100), FUP(0x110c), TIP(0xcc00) |

Generation of the following packets may cause a partial TNT (and any accumulated TIPs) to be sent:

- Flow Update Packet (FUP)
- TIP due to uncompressed RET
- TIP.PGE and TIP.PGD
- Paging Information Packet (PIP)
- MODE
- Packet Stream Boundary (PSB)
- Core Bus Ratio (CBR)

As stated above, the processor may opt to send partial TNTs when TIPs are generated as well.

### 36.4.2.4 Packet Generation Enable (TIP.PGE)

**Table 36-16. TIP.PGE Packet Definition**

| Name | Target IP - Packet Generation Enable (TIP.PGE) | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Packet Format | | | | | | | | |
| | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | IPBytes | | | 1 | 0 | 0 | 0 | 1 |
| 1 | TargetIP[7:0] | | | | | | | |
| 2 | TargetIP[15:8] | | | | | | | |
| 3 | TargetIP[23:16] | | | | | | | |
| 4 | TargetIP[31:24] | | | | | | | |
| 5 | TargetIP[39:32] | | | | | | | |
| 6 | TargetIP[47:40] | | | | | | | |

**Table 36-16. TIP.PGE Packet Definition**

| | | | |
|---|---|---|---|
| Dependencies | PacketEn transitions to 1 | Generation Scenario | Any branch instruction, control flow transfer, or MOV CR3 that sets PacketEn, a WRMSR that enables packet generation and sets PacketEn |
| Description | Indicates that PacketEn has transitioned to 1. It provides the IP at which the tracing begins.<br>This can occur due to any of the enables that comprise PacketEn transitioning from 0 to 1, as long as all the others are asserted. Examples<br>▪ TriggerEn: This is set on software write to set IA32_RTIT_CTL.TraceEn as long as the Stopped and Error bits in IA32_RTIT_STATUS are clear. The IP payload will be the Next IP of the WRMSR.<br>▪ ContextEn: This is set on a CPL change, a CR3 write. The IP payload will be the Next IP of the instruction that changes context, if it is not a branch, otherwise it will be the target of the branch | | |
| Application | TIP.PGE packets bind to the instruction at the IP given in the payload. | | |

### 36.4.2.5 Packet Generation Disable (TIP.PGD)

**Table 36-17. TIP.PGD Packet Definition**

| | | | |
|---|---|---|---|
| Name | Target IP - Packet Generation Disable (TIP.PGD) | | |
| Packet Format | | | |

| | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| 0 | IPBytes | | | 0 | 0 | 0 | 0 | 1 |
| 1 | TargetIP[7:0] | | | | | | | |
| 2 | TargetIP[15:8] | | | | | | | |
| 3 | TargetIP[23:16] | | | | | | | |
| 4 | TargetIP[31:24] | | | | | | | |
| 5 | TargetIP[39:32] | | | | | | | |
| 6 | TargetIP[47:40] | | | | | | | |

| | | | |
|---|---|---|---|
| Dependencies | PacketEn transitions to 0 | Generation Scenario | Any branch instruction, control flow transfer, or MOV CR3 that clears PacketEn, a WRMSR that disables packet generation and clears PacketEn |
| Description | Indicates that PacketEn has transitioned to 0. It will include the IP at which the tracing ends, unless ContextEn= 0 or TraceEn=0 at the conclusion of the instruction or event that cleared PacketEn.<br>PacketEn can be cleared due to any of the enables that comprise PacketEn transitioning from 1 to 0. Examples:<br>▪ TriggerEn: This is cleared on software write to clear IA32_RTIT_CTL.TraceEn, or on ToPA STOP, or on operational error. The IP payload will be suppressed in this case, and the "IPBytes" field will have the value 0.<br>▪ ContextEn: This can happen on a CPL change, or a CR3 write. See Section 36.2.3.3 for details. In this case, when ContextEn is cleared, there will be no IP payload. The "IPBytes" field will have value 0<br>Note that, in cases where a branch that would normally produce a TIP packet (i.e., far transfer, indirect branch, interrupt, etc) or TNT update (conditional branch or compressed RT) causes PacketEn to transition from 1 to 0, the TIP or TNI bit will be replaced with TIP.PGD. | | |
| Application | TIP.PGD can be produced by any branch instructions, as well as some non-branch instructions, that clear PacketEn. When produced by a branch, it replaces any TIP or TNT update that the branch would normally produce.<br>In cases where there is an unbound FUP preceding the TIP.PGD, then the TIP.PGD is part of compound operation (i.e., asynchronous event or TSX abort) which cleared PacketEn. For most such cases, the TIP.PGD is simply replacing a TIP, and should be treated the same way.<br>If there is not an associated FUP, the binding will depend on whether there is an IP payload. If there is an IP payload, then the TIP.PGD should be applied to either the next direct branch whose target matches the TIP.PGD payload, or the next branch that would normally generate a TIP or TNT packet. If there is no IP payload, then the TIP.PGD should apply to the next branch or MOV CR3 instruction | | |

### 36.4.2.6 Flow Update (FUP) Packet

**Table 36-18. FUP Packet Definition**

<table>
<tr><td>Name</td><td colspan="4">Float Update (FUP) Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><th></th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>0</td><td colspan="3">IPBytes</td><td>1</td><td>1</td><td>1</td><td>0</td><td>1</td></tr>
<tr><td>1</td><td colspan="8">IP[7:0]</td></tr>
<tr><td>2</td><td colspan="8">IP[15:8]</td></tr>
<tr><td>3</td><td colspan="8">IP[23:16]</td></tr>
<tr><td>4</td><td colspan="8">IP[31:24]</td></tr>
<tr><td>5</td><td colspan="8">IP[39:32]</td></tr>
<tr><td>6</td><td colspan="8">IP[47:40]</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>PacketEn</td><td>Generation Scenario</td><td colspan="2">Asynchronous Events (interrupts, exceptions, INIT, SIPI, SMI, #MC), XBEGIN, XEND, XABORT, XACQUIRE, XRELEASE, a WRMSR that disables packet generation, PSB+</td></tr>
<tr><td>Description</td><td colspan="4">Provides the source address for asynchronous events, and some other instructions. Is never sent alone, always sent with an associated TIP or MODE packet, and potentially others</td></tr>
<tr><td>Application</td><td colspan="4">FUP packets provide the IP to which they bind. However, they are never standalone, but are coupled with other packets.<br>In TSX cases, the FUP is immediately preceded by a MODE.TSX, which binds to the same IP. A TIP will follow only in the case of TSX aborts, see Section 36.4.2.8 for details.<br>Otherwise, FUPs are part of compound packet events (see Section 36.4.1). In these compound cases, the FUP provides the source IP for an instruction or event, while a following TIP (or TIP.PGD) uop will provide any destination IP. Other packets may be included in the compound event between the FUP and TIP.</td></tr>
</table>

#### FUP IP Payload

Flow Update Packet gives the source address of an instruction when it is needed. In general, branch instructions do not need a FUP, because the source address is clear from the disassembly. For asynchronous events, however, the source address cannot be inferred from the source, and hence a FUP will be sent. Table 36-19 illustrates cases where FUPs are sent, and which IP can be expected in those cases.

**Table 36-19. FUP Cases and IP Payload**

| Event | Flow Update IP | Comment |
|---|---|---|
| External Interrupt, NMI/SMI, Traps, Machine Check (trap-like), Software Interrupt, INIT/SIPI | Address of next instruction (Next IP) that would have been executed | Functionally, this matches the LBR FROM field value. |
| Exceptions/Faults, Machine check (fault-like) | Address of the instruction which took the exception/fault (Current IP) | This matches the similar functionality of LBR FROM field value. |
| XACQUIRE | Address of the X* instruction | |
| XRELEASE, XBEGIN, XEND, XABORT, other transactional abort | Current IP | |
| #SMI | IP that is saved into SMRAM | |
| WRMSR that clears TraceEn | Current IP | |

On a canonical fault due to sequentially fetching an instruction in non-canonical space (as opposed to jumping to non-canonical space), the IP of the fault (and thus the payload of the FUP) will be a non-canonical address. This is consistent with what is pushed on the stack for such faulting cases.

### 36.4.2.7 Paging Information (PIP) Packet

**Table 36-20. PIP Packet Definition**

<table>
<tr><td>Name</td><td colspan="4">Paging Information (PIP) Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><th></th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>1</td><td>0</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>1</td></tr>
<tr><td>2</td><td colspan="7">CR3[11:5] or 0</td><td>RSVD</td></tr>
<tr><td>3</td><td colspan="8">CR3[19:12]</td></tr>
<tr><td>4</td><td colspan="8">CR3[27:20]</td></tr>
<tr><td>5</td><td colspan="8">CR3[35:28]</td></tr>
<tr><td>6</td><td colspan="8">CR3[43:36]</td></tr>
<tr><td>7</td><td colspan="8">CR3[51:44]</td></tr>
</table>
The CR3 payload shown includes only the address portion of the CR3 value. For PAE paging, CR3[11:5] are thus included. For other page modes (32-bit and IA-32e paging), these bits are 0.
</td></tr>
<tr><td>Dependencies</td><td>TriggerEn && ContextEn && IA32_RTIT_CTL.OS</td><td>Generation Scenario</td><td colspan="2">MOV CR3, Task switch, INIT, SIPI, PSB+</td></tr>
<tr><td>Description</td><td colspan="4">This packet holds the CR3 address value. It will be generated on operations that modify CR3:<br>▪ MOV CR3 operation<br>▪ Task Switch<br>▪ INIT and SIPI<br>PIPs are not generated, despite changes to CR3, on SMI and RSM. This is due to the special behavior on these operations, see Section 36.2.6.2 for details. Note that, for some cases of task switch where CR3 is not modified, no PIP will be produced.<br>The purpose of the PIP is to indicate to the decoder which application is running, so that it can apply the proper binaries to the linear addresses that are being traced.<br>The PIP packet contains the new CR3 value when CR3 is written</td></tr>
<tr><td>Application</td><td colspan="4">The purpose of the PIP packet is to help the decoder uniquely identify what software is running at any given time. When a PIP is encountered, a decoder should do the following:<br>1) If there was a prior unbound FUP (that is, a FUP not preceded by MODE.TSX, and hence pairs with a TIP that has not yet been seen), then this PIP is part of a compound packet event (Section 36.4.1). Find the ending TIP and apply the new CR3 values to the TIP payload IP.<br>2) Look for the next MOV CR3 or far branch in the disassembly, and apply the new CR3 to the next (or target) IP.<br>For examples of the packets generated by these flows, see Section 36.4.3</td></tr>
</table>

### 36.4.2.8 MODE Packets

MODE packets keep the decoder informed of various processor modes about which it needs to know in order to properly manage the packet output, or to properly disassemble the associated binaries. MODE packets include a header and a mode byte, as shown below.

**Table 36-21. General Form of MODE Packets**

| | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|---|---|---|---|---|---|---|
| 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 | 1 |
| 1 | Leaf ID | | | Mode | | | | |

The MODE Leaf ID indicates which set of mode bits are held in the lower bits.

## MODE.Exec Packet

### Table 36-22. MODE.Exec Packet Definition

<table>
<tr><td>Name</td><td colspan="4">MODE.Exec Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td>0</td><td>1</td><td>0</td><td>0</td><td>1</td><td>1</td><td>0</td><td>0</td><td>1</td></tr>
<tr><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>CS.D</td><td>(CS.L & LMA)</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>PacketEn</td><td>Generation Scenario</td><td colspan="2">Far branch, interrupt, exception, PSB+, and any scenario that can generate a TIP.PGE</td></tr>
<tr><td>Description</td><td colspan="4">Indicates whether software is in 16, 32, or 64-bit mode, by providing the CS.D and (CS.L & IA32_EFER.LMA) values. Essential for the decoder to properly disassemble the associated binary.<br><br>
<table>
<tr><td>CS.D</td><td>(CS.L & IA32_EFER.LMA)</td><td>Addressing Mode</td></tr>
<tr><td>1</td><td>1</td><td>N/A</td></tr>
<tr><td>0</td><td>1</td><td>64-bit mode</td></tr>
<tr><td>1</td><td>0</td><td>32-bit mode</td></tr>
<tr><td>0</td><td>0</td><td>16-bit mode</td></tr>
</table>
<br>For cases where the mode changes while TraceEn=1 but PacketEn=0 (i.e., when packet generation is enabled but software is out of context), and the mode change persists once tracing resumes (once PacketEn=1), the processor will send a MODE.Exec packet preceding the subsequent TIP.PGE. Further, any time packet generation is disabled, if it is re-enabled the first TIP.PGE will be preceded by a MODE.Exec packet. This serves to cover cases where the mode changes while packet generation is disabled.</td></tr>
<tr><td>Application</td><td colspan="4">MODE.Exec always immediately precedes a TIP or TIP.PGE. The mode change applies to the IP address in the payload of the next TIP or TIP.PGE.</td></tr>
</table>

## MODE.TSX Packet

### Table 36-23. MODE.TSX Packet Definition

<table>
<tr><td>Name</td><td colspan="4">MODE.TSX Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4">
<table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td>0</td><td>1</td><td>0</td><td>0</td><td>1</td><td>1</td><td>0</td><td>0</td><td>1</td></tr>
<tr><td>1</td><td>0</td><td>0</td><td>1</td><td>0</td><td>0</td><td>0</td><td>TXAbort</td><td>InTX</td></tr>
</table>
</td></tr>
<tr><td>Dependencies</td><td>TriggerEn and ContextEn</td><td>Generation Scenario</td><td colspan="2">XBEGIN, XEND, XABORT, XACQUIRE, XRELEASE, Asynchronous TSX Abort</td></tr>
</table>

**Table 36-23. MODE.TSX Packet Definition**

| | |
|---|---|
| Description | Indicates when a TSX transaction (either HLE or RTM) begins, commits, or aborts. Instructions executed transactionally will be "rolled back" if the transaction is aborted.<br><br>TXAbort / InTX / Implication:<br>1 / 1 / N/A<br>0 / 1 / Transaction begins, or executing transactionally<br>1 / 0 / Transaction aborted<br>0 / 0 / Transaction committed, or not executing transactionally |
| Application | MODE.TSX always immediately precedes a FUP. If the TXAbort bit is zero, then the mode change applies to the IP address in the payload of the FUP. If TXAbort=1, then the FUP will be followed by a TIP, and the mode change will apply to the IP address in the payload of the TIP. |

### 36.4.2.9 Core:Bus Ratio (CBR) Packet

**Table 36-24. CBR Packet Definition**

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Name | Core:Bus Ratio (CBR) Packet | | | | | | | |
| Packet Format | | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |
| | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 |
| | 2 | Core:Bus Ratio | | | | | | | |
| | 3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Dependencies | TriggerEn | | Generation Scenario | Any change to core:bus ratio (frequency change, sleep state wake), PSB+, and after modifying configuration MSR enable | | | | |
| Description | Indicates the core:bus ratio of the processor core. Byte 2 represents the number of core clock cycles per bus clock cycle. Useful for correlating wall-clock time and cycle time | | | | | | | |
| Application | When TSC packets are enabled, a TSC packet will precede the CBR. If there was a core:bus ratio (frequency) change, the TSC payload provides the time at which it occurred.<br>All packets following the CBR represent instructions that executed with the new core:bus ratio, while all preceding packets (aside from the associated TSC) represent instructions that executed with the prior ratio. There is not a precise IP to which to bind the CBR packet. | | | | | | | |

### 36.4.2.10 Timestamp Counter (TSC) Packet

**Table 36-25. TSC Packet Definition**

| | |
|---|---|
| Name | Timestamp Counter (TSC) Packet |

**Table 36-25. TSC Packet Definition**

<table>
<tr><td>Packet Format</td><td colspan="4"><table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>1</td><td>0</td><td>0</td><td>1</td></tr>
<tr><td>1</td><td colspan="8">SW TSC[7:0]</td></tr>
<tr><td>2</td><td colspan="8">SW TSC[15:8]</td></tr>
<tr><td>3</td><td colspan="8">SW TSC[23:16]</td></tr>
<tr><td>4</td><td colspan="8">SW TSC[31:24]</td></tr>
<tr><td>5</td><td colspan="8">SW TSC[39:32]</td></tr>
<tr><td>6</td><td colspan="8">SW TSC[47:40]</td></tr>
<tr><td>7</td><td colspan="8">SW TSC[55:48]</td></tr>
</table></td></tr>
<tr><td>Dependencies</td><td>IA32_RTIT_CTL.TSCEn && TriggerEn</td><td>Generation Scenario</td><td>Any change to core:bus ratio (with CBR packet), sleep state wake, STPCLK, PSB+, and on transition of TraceEn from 0 to 1.</td></tr>
<tr><td>Description</td><td colspan="3">When enabled by software, TSC provides the lower 7 bytes of the current TSC value, as returned by the RDTSC instruction. This may be useful for tracking wall-clock time, and synchronizing the packets in the log with other time-stamped logs</td></tr>
<tr><td>Application</td><td colspan="3">TSC packet provides a wall-clock proxy of the event which generated it (packet generation enable, sleep state wake, etc). In all cases, TSC is sent preceding a CBR. TSC does not precisely indicate the time of any control flow packets; however, all preceding packets represent instructions that executed before the indicated TSC time, and all subsequent packets represent instructions that executed after it. There is not a precise IP to which to bind the TSC packet</td></tr>
</table>

### 36.4.2.11 Overflow (OVF) Packet

**Table 36-26. OVF Packet Definition**

<table>
<tr><td>Name</td><td colspan="3">Overflow (OVF) Packet</td></tr>
<tr><td>Packet Format</td><td colspan="3"><table>
<tr><td></td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>1</td><td>1</td><td>1</td><td>1</td><td>1</td><td>0</td><td>0</td><td>1</td><td>1</td></tr>
</table></td></tr>
<tr><td>Dependencies</td><td>TriggerEn</td><td>Generation Scenario</td><td>On resolution of internal buffer overflow</td></tr>
<tr><td>Description</td><td colspan="3">OVF simply indicates to the decoder that an internal buffer overflow occurred, and packets were likely lost. OVF is followed by a FUP or TIP.PGE which will indicate the point at which packet generation resumes. See Section 36.3.6</td></tr>
<tr><td>Application</td><td colspan="3">When an OVF packet is encountered, the decoder should skip to the IP given in the following FUP or TIP.PGE. Software should reset its call stack depth on overflow, since no RET compression is allowed across an overflow. Similarly, any IP compression that follows the OVF is guaranteed to use as a reference LastIP the IP payload of an IP packet that was not dropped</td></tr>
</table>

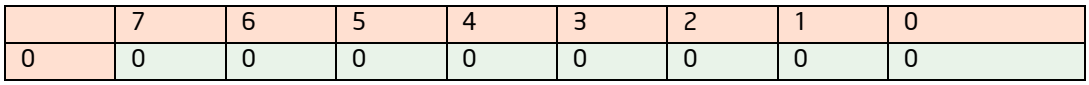
### 36.4.2.12 Packet Stream Boundary (PSB) Packet

**Table 36-27. PSB Packet Definition**

| Name | Packet Stream Boundary (PSB) Packet |
|---|---|

**Table 36-27. PSB Packet Definition**

<table>
<tr><td>Packet Format</td><td colspan="4"><table>
<tr><th></th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>1</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>2</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>3</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>4</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>5</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>6</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>7</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>8</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>9</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>10</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>11</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>12</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>13</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>14</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>15</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
</table></td></tr>
<tr><td>Dependencies</td><td>TriggerEn</td><td>Generation Scenario</td><td colspan="2">The frequency of PSB packet generation is implementation specific.</td></tr>
<tr><td>Description</td><td colspan="4">PSB is a unique pattern in the packet output log, and hence serves as a sync point for the decoder. It is a pattern that the decoder can search for in order to get aligned on packet boundaries.<br>PSB also serves as the leading packet for a set of “status-only” packets collectively known as PSB+ (Section 36.3.5).</td></tr>
<tr><td>Application</td><td colspan="4">When a PSB is seen, the decoder should interpret all following packets as “status only”, until either a PSBEND or OVF packet is encountered. “Status only” implies that the binding and ordering rules to which these packets normally adhere are ignored, and the state they carry can instead be applied to the IP payload in the FUP packet that is included.</td></tr>
</table>



### 36.4.2.13 PSBEND Packet

**Table 36-28. PSBEND Packet Definition**

<table>
<tr><td>Name</td><td colspan="4">PSBEND Packet</td></tr>
<tr><td>Packet Format</td><td colspan="4"><table>
<tr><th></th><th>7</th><th>6</th><th>5</th><th>4</th><th>3</th><th>2</th><th>1</th><th>0</th></tr>
<tr><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>1</td><td>0</td><td>0</td><td>1</td><td>0</td><td>0</td><td>0</td><td>1</td><td>1</td></tr>
</table></td></tr>
<tr><td>Dependencies</td><td>TriggerEn</td><td>Generation Scenario</td><td colspan="2">Always follows PSB packet, separated by PSB+ packets</td></tr>
<tr><td>Description</td><td colspan="4">PSBEND is simply a terminator for the series of “status only” (PSB+) packets that follow PSB (Section 36.3.5).</td></tr>
<tr><td>Application</td><td colspan="4">When a PSBEND packet is seen, the decoder should cease to treat packets as “status only”.</td></tr>
</table>

### 36.4.2.14 PAD Packet

**Table 36-29. PAD Packet Definition**

| Name | PAD Packet | | |
|---|---|---|---|
| Packet Format |  | | |
| Dependencies | TriggerEn | Generation Scenario | Implementation specific |
| Description | PAD is simply a NOP packet. Processor implementations may choose to add pad packets to improve packet alignment or for implementation-specific reasons. | | |
| Application | Ignore PAD packets | | |

## 36.4.3 Packet Generation Scenarios

Table 36-30 illustrates the packets generated in various scenarios. Note that this assumes that TraceEn=1 in IA32_RTIT_CTL, while TriggerEn=1 and Error=0 in IA32_RTIT_STATUS, unless otherwise specified. Entries that do not matter in packet generation are marked "D.C."

**Table 36-30. Packet Generation under Different Enable Conditions**

## 36.5 SOFTWARE CONSIDERATIONS

### 36.5.1 Tracing SMM Code

Nothing prevents an SMM handler from configuring and enabling packet generation for its own use. As described in Section 36.2.6.2, SMI will always clear TraceEn, so the SMM handler would have to set TraceEn in order to enable tracing. There are some unique aspects and guidelines involved with tracing SMM code, which follows:

1. SMM should save away the existing values of any configuration MSRs that SMM intends to modify for tracing. This will allow the non-SMM tracing context to be restored before RSM.
2. It is recommended that SMM wait until it sets CSbase to 0 before enabling packet generation, to avoid possible LIP vs RIP confusion (see Section 36.3.1.1).
3. Packet output cannot be directed to SMRR memory, even while tracing in SMM.
4. Before performing RSM, SMM should take care to restore modified configuration MSRs to the values they had immediately after #SMI. This involves first disabling packet generation by clearing TraceEn, then restoring any other configuration MSRs that were modified.

### 36.5.2 Cooperative Transition of Multiple Trace Collection Agents

A third-party trace-collection tool should take into consideration the fact that it may be deployed on a processor that supports Intel PT but may run under any operating system.

In such a deployment scenario, Intel recommends that tool agents follow similar principles of cooperative transition of single-use hardware resources, similar to how performance monitoring tools handle performance monitoring hardware:

- Respect the "in-use" ownership of an agent who already configured the trace configuration MSRs, see architectural MSRs with the prefix "IA32_RTIT_" in Chapter 35, "Model-Specific Registers (MSRs)", where "in-use" can be determined by reading the "enable bits" in the configuration MSRs.
- Relinquish ownership of the trace configuration MSRs by clearing the "enabled bits" of those configuration MSRs.

# APPENDIX A
# VMX CAPABILITY REPORTING FACILITY

The ability of a processor to support VMX operation and related instructions is indicated by CPUID.1:ECX.VMX[bit 5] = 1. A value 1 in this bit indicates support for VMX features.

Support for specific features detailed in Chapter 26 and other VMX chapters is determined by reading values from a set of capability MSRs. These MSRs are indexed starting at MSR address 480H. VMX capability MSRs are read-only; an attempt to write them (with WRMSR) produces a general-protection exception (#GP(0)). They do not exist on processors that do not support VMX operation; an attempt to read them (with RDMSR) on such processors produces a general-protection exception (#GP(0)).

## A.1 BASIC VMX INFORMATION

The IA32_VMX_BASIC MSR (index 480H) consists of the following fields:

- Bits 30:0 contain the 31-bit VMCS revision identifier used by the processor. Processors that use the same VMCS revision identifier use the same size for VMCS regions (see subsequent item on bits 44:32).[1]
- Bit 31 is always 0.
- Bits 44:32 report the number of bytes that software should allocate for the VMXON region and any VMCS region. It is a value greater than 0 and at most 4096 (bit 44 is set if and only if bits 43:32 are clear).
- Bit 48 indicates the width of the physical addresses that may be used for the VMXON region, each VMCS, and data structures referenced by pointers in a VMCS (I/O bitmaps, virtual-APIC page, MSR areas for VMX transitions). If the bit is 0, these addresses are limited to the processor's physical-address width.[2] If the bit is 1, these addresses are limited to 32 bits. This bit is always 0 for processors that support Intel 64 architecture.
- If bit 49 is read as 1, the logical processor supports the dual-monitor treatment of system-management interrupts and system-management mode. See Section 34.15 for details of this treatment.
- Bits 53:50 report the memory type that the logical processor uses to access the VMCS for VMREAD and VMWRITE and to access the VMCS, data structures referenced by pointers in the VMCS (I/O bitmaps, virtual-APIC page, MSR areas for VMX transitions), and the MSEG header during VM entries, VM exits, and in VMX non-root operation.[3]

  The first processors to support VMX operation use the write-back type. The values used are given in Table A-1.

**Table A-1. Memory Types Used For VMCS Access**

| Value(s) | Field |
|---|---|
| 0 | Uncacheable (UC) |
| 1–5 | Not used |
| 6 | Write Back (WB) |
| 7–15 | Not used |

1. Earlier versions of this manual specified that the VMCS revision identifier was a 32-bit field in bits 31:0 of this MSR. For all processors produced prior to this change, bit 31 of this MSR was read as 0.
2. On processors that support Intel 64 architecture, the pointer must not set bits beyond the processor's physical address width.
3. If the MTRRs are disabled by clearing the E bit (bit 11) in the IA32_MTRR_DEF_TYPE MSR, the logical processor uses the UC memory type to access the indicated data structures, regardless of the value reported in bits 53:50 in the IA32_VMX_BASIC MSR. The processor will also use the UC memory type if the setting of CR0.CD on this logical processor (or another logical processor on the same physical processor) would cause it to do so for all memory accesses. The values of IA32_MTRR_DEF_TYPE.E and CR0.CD do not affect the value reported in IA32_VMX_BASIC[53:50].

If software needs to access these data structures (e.g., to modify the contents of the MSR bitmaps), it can configure the paging structures to map them into the linear-address space. If it does so, it should establish mappings that use the memory type reported in this MSR.[1]

- If bit 54 is read as 1, the logical processor reports information in the VM-exit instruction-information field on VM exits due to execution of the INS and OUTS instructions. This reporting is done only if this bit is read as 1.
- Bit 55 is read as 1 if any VMX controls that default to 1 may be cleared to 0. See Appendix A.2 for details. It also reports support for the VMX capability MSRs IA32_VMX_TRUE_PINBASED_CTLS, IA32_VMX_TRUE_PROCBASED_CTLS, IA32_VMX_TRUE_EXIT_CTLS, and IA32_VMX_TRUE_ENTRY_CTLS. See Appendix A.3.1, Appendix A.3.2, Appendix A.4, and Appendix A.5 for details.
- The values of bits 47:45 and bits 63:56 are reserved and are read as 0.

## A.2 RESERVED CONTROLS AND DEFAULT SETTINGS

As noted in Chapter 26, "VM Entries", certain VMX controls are reserved and must be set to a specific value (0 or 1) determined by the processor. The specific value to which a reserved control must be set is its **default setting**. Software can discover the default setting of a reserved control by consulting the appropriate VMX capability MSR (see Appendix A.3 through Appendix A.5).

Future processors may define new functionality for one or more reserved controls. Such processors would allow each newly defined control to be set either to 0 or to 1. Software that does not desire a control's new functionality should set the control to its default setting. For that reason, it is useful for software to know the default settings of the reserved controls.

Default settings partition the various controls into the following classes:

- **Always-flexible**. These have never been reserved.
- **Default0**. These are (or have been) reserved with a default setting of 0.
- **Default1**. They are (or have been) reserved with a default setting of 1.

As noted in Appendix A.1, a logical processor uses bit 55 of the IA32_VMX_BASIC MSR to indicate whether any of the default1 controls may be 0:

- If bit 55 of the IA32_VMX_BASIC MSR is read as 0, all the default1 controls are reserved and must be 1. VM entry will fail if any of these controls are 0 (see Section 26.2.1).
- If bit 55 of the IA32_VMX_BASIC MSR is read as 1, not all the default1 controls are reserved, and some (but not necessarily all) may be 0. The CPU supports four (4) new VMX capability MSRs: IA32_VMX_TRUE_PINBASED_CTLS, IA32_VMX_TRUE_PROCBASED_CTLS, IA32_VMX_TRUE_EXIT_CTLS, and IA32_VMX_TRUE_ENTRY_CTLS. See Appendix A.3 through Appendix A.5 for details. (These MSRs are not supported if bit 55 of the IA32_VMX_BASIC MSR is read as 0.)

See Section 31.5.1 for recommended software algorithms for proper capability detection of the default1 controls.

## A.3 VM-EXECUTION CONTROLS

There are separate capability MSRs for the pin-based VM-execution controls, the primary processor-based VM-execution controls, and the secondary processor-based VM-execution controls. These are described in Appendix A.3.1, Appendix A.3.2, and Appendix A.3.3, respectively.

1. Alternatively, software may map any of these regions or structures with the UC memory type. (This may be necessary for the MSEG header.) Doing so is discouraged unless necessary as it will cause the performance of software accesses to those structures to suffer. The processor will continue to use the memory type reported in the VMX capability MSR IA32_VMX_BASIC with the exceptions noted.

### A.3.1 Pin-Based VM-Execution Controls

The IA32_VMX_PINBASED_CTLS MSR (index 481H) reports on the allowed settings of **most** of the pin-based VM-execution controls (see Section 24.6.1):

- Bits 31:0 indicate the **allowed 0-settings** of these controls. VM entry allows control X (bit X of the pin-based VM-execution controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

  Exceptions are made for the pin-based VM-execution controls in the default1 class (see Appendix A.2). These are bits 1, 2, and 4; the corresponding bits of the IA32_VMX_PINBASED_CTLS MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32_VMX_BASIC MSR:

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 0, VM entry fails if any pin-based VM-execution control in the default1 class is 0.

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_PINBASED_CTLS MSR (see below) reports which of the pin-based VM-execution controls in the default1 class can be 0 on VM entry.

- Bits 63:32 indicate the **allowed 1-settings** of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_PINBASED_CTLS MSR (index 48DH) reports on the allowed settings of **all** of the pin-based VM-execution controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the pin-based VM-execution controls:

- If bit 55 in the IA32_VMX_BASIC MSR is read as 0, all information about the allowed settings of the pin-based VM-execution controls is contained in the IA32_VMX_PINBASED_CTLS MSR. (The IA32_VMX_TRUE_PINBASED_CTLS MSR is not supported.)
- If bit 55 in the IA32_VMX_BASIC MSR is read as 1, all information about the allowed settings of the pin-based VM-execution controls is contained in the IA32_VMX_TRUE_PINBASED_CTLS MSR. Assuming that software knows that the default1 class of pin-based VM-execution controls contains bits 1, 2, and 4, there is no need for software to consult the IA32_VMX_PINBASED_CTLS MSR.

### A.3.2 Primary Processor-Based VM-Execution Controls

The IA32_VMX_PROCBASED_CTLS MSR (index 482H) reports on the allowed settings of **most** of the primary processor-based VM-execution controls (see Section 24.6.2):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the primary processor-based VM-execution controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

  Exceptions are made for the primary processor-based VM-execution controls in the default1 class (see Appendix A.2). These are bits 1, 4–6, 8, 13–16, and 26; the corresponding bits of the IA32_VMX_PROCBASED_CTLS MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32_VMX_BASIC MSR:

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 0, VM entry fails if any of the primary processor-based VM-execution controls in the default1 class is 0.

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_PROCBASED_CTLS MSR (see below) reports which of the primary processor-based VM-execution controls in the default1 class can be 0 on VM entry.

- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_PROCBASED_CTLS MSR (index 48EH) reports on the allowed settings of **all** of the primary processor-based VM-execution controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the primary processor-based VM-execution controls:

- If bit 55 in the IA32_VMX_BASIC MSR is read as 0, all information about the allowed settings of the primary processor-based VM-execution controls is contained in the IA32_VMX_PROCBASED_CTLS MSR. (The IA32_VMX_TRUE_PROCBASED_CTLS MSR is not supported.)
- If bit 55 in the IA32_VMX_BASIC MSR is read as 1, all information about the allowed settings of the processor-based VM-execution controls is contained in the IA32_VMX_TRUE_PROCBASED_CTLS MSR. Assuming that software knows that the default1 class of processor-based VM-execution controls contains bits 1, 4–6, 8, 13–16, and 26, there is no need for software to consult the IA32_VMX_PROCBASED_CTLS MSR.

### A.3.3 Secondary Processor-Based VM-Execution Controls

The IA32_VMX_PROCBASED_CTLS2 MSR (index 48BH) reports on the allowed settings of the secondary processor-based VM-execution controls (see Section 24.6.2). VM entries perform the following checks:

- Bits 31:0 indicate the allowed 0-settings of these controls. These bits are always 0. This fact indicates that VM entry allows each bit of the secondary processor-based VM-execution controls to be 0 (reserved bits must be 0)
- Bits 63:32 indicate the allowed 1-settings of these controls; the 1-setting is not allowed for any reserved bit. VM entry allows control X (bit X of the secondary processor-based VM-execution controls) to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X and the "activate secondary controls" primary processor-based VM-execution control are both 1.

The IA32_VMX_PROCBASED_CTLS2 MSR exists only on processors that support the 1-setting of the "activate secondary controls" VM-execution control (only if bit 63 of the IA32_VMX_PROCBASED_CTLS MSR is 1).

## A.4 VM-EXIT CONTROLS

The IA32_VMX_EXIT_CTLS MSR (index 483H) reports on the allowed settings of **most** of the VM-exit controls (see Section 24.7.1):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the VM-exit controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

  Exceptions are made for the VM-exit controls in the default1 class (see Appendix A.2). These are bits 0–8, 10, 11, 13, 14, 16, and 17; the corresponding bits of the IA32_VMX_EXIT_CTLS MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32_VMX_BASIC MSR:

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 0, VM entry fails if any VM-exit control in the default1 class is 0.

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_EXIT_CTLS MSR (see below) reports which of the VM-exit controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control 32+X to be 1 if bit X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_EXIT_CTLS MSR (index 48FH) reports on the allowed settings of **all** of the VM-exit controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.

- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the VM-exit controls:

- If bit 55 in the IA32_VMX_BASIC MSR is read as 0, all information about the allowed settings of the VM-exit controls is contained in the IA32_VMX_EXIT_CTLS MSR. (The IA32_VMX_TRUE_EXIT_CTLS MSR is not supported.)
- If bit 55 in the IA32_VMX_BASIC MSR is read as 1, all information about the allowed settings of the VM-exit controls is contained in the IA32_VMX_TRUE_EXIT_CTLS MSR. Assuming that software knows that the default1 class of VM-exit controls contains bits 0–8, 10, 11, 13, 14, 16, and 17, there is no need for software to consult the IA32_VMX_EXIT_CTLS MSR.

## A.5 VM-ENTRY CONTROLS

The IA32_VMX_ENTRY_CTLS MSR (index 484H) reports on the allowed settings of **most** of the VM-entry controls (see Section 24.8.1):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the VM-entry controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

  Exceptions are made for the VM-entry controls in the default1 class (see Appendix A.2). These are bits 0–8 and 12; the corresponding bits of the IA32_VMX_ENTRY_CTLS MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32_VMX_BASIC MSR:

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 0, VM entry fails if any VM-entry control in the default1 class is 0.

  — If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_ENTRY_CTLS MSR (see below) reports which of the VM-entry controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry fails if bit X is 1 in the VM-entry controls and bit 32+X is 0 in this MSR.

If bit 55 in the IA32_VMX_BASIC MSR is read as 1, the IA32_VMX_TRUE_ENTRY_CTLS MSR (index 490H) reports on the allowed settings of **all** of the VM-entry controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control 32+X to be 1 if bit X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the VM-entry controls:

- If bit 55 in the IA32_VMX_BASIC MSR is read as 0, all information about the allowed settings of the VM-entry controls is contained in the IA32_VMX_ENTRY_CTLS MSR. (The IA32_VMX_TRUE_ENTRY_CTLS MSR is not supported.)
- If bit 55 in the IA32_VMX_BASIC MSR is read as 1, all information about the allowed settings of the VM-entry controls is contained in the IA32_VMX_TRUE_ENTRY_CTLS MSR. Assuming that software knows that the default1 class of VM-entry controls contains bits 0–8 and 12, there is no need for software to consult the IA32_VMX_ENTRY_CTLS MSR.

## A.6 MISCELLANEOUS DATA

The IA32_VMX_MISC MSR (index 485H) consists of the following fields:

- Bits 4:0 report a value X that specifies the relationship between the rate of the VMX-preemption timer and that of the timestamp counter (TSC). Specifically, the VMX-preemption timer (if it is active) counts down by 1 every time bit X in the TSC changes due to a TSC increment.

- If bit 5 is read as 1, VM exits store the value of IA32_EFER.LMA into the "IA-32e mode guest" VM-entry control; see Section 27.2 for more details. This bit is read as 1 on any logical processor that supports the 1-setting of the "unrestricted guest" VM-execution control.
- Bits 8:6 report, as a bitmap, the activity states supported by the implementation:
  - — Bit 6 reports (if set) the support for activity state 1 (HLT).
  - — Bit 7 reports (if set) the support for activity state 2 (shutdown).
  - — Bit 8 reports (if set) the support for activity state 3 (wait-for-SIPI).

  If an activity state is not supported, the implementation causes a VM entry to fail if it attempts to establish that activity state. All implementations support VM entry to activity state 0 (active).
- If bit 15 is read as 1, the RDMSR instruction can be used in system-management mode (SMM) to read the IA32_SMBASE MSR (MSR address 9EH). See Section 34.15.6.4.
- Bits 24:16 indicate the number of CR3-target values supported by the processor. This number is a value between 0 and 256, inclusive (bit 24 is set if and only if bits 23:16 are clear).
- Bits 27:25 is used to compute the recommended maximum number of MSRs that should appear in the VM-exit MSR-store list, the VM-exit MSR-load list, or the VM-entry MSR-load list. Specifically, if the value bits 27:25 of IA32_VMX_MISC is N, then 512 * (N + 1) is the recommended maximum number of MSRs to be included in each list. If the limit is exceeded, undefined processor behavior may result (including a machine check during the VMX transition).
- If bit 28 is read as 1, bit 2 of the IA32_SMM_MONITOR_CTL can be set to 1. VMXOFF unblocks SMIs unless IA32_SMM_MONITOR_CTL[bit 2] is 1 (see Section 34.14.4).
- If bit 29 is read as 1, software can use VMWRITE to write to any supported field in the VMCS; otherwise, VMWRITE cannot be used to modify VM-exit information fields.
- Bits 63:32 report the 32-bit MSEG revision identifier used by the processor.
- Bits 14:9 and bits 31:30 are reserved and are read as 0.

## A.7 VMX-FIXED BITS IN CR0

The IA32_VMX_CR0_FIXED0 MSR (index 486H) and IA32_VMX_CR0_FIXED1 MSR (index 487H) indicate how bits in CR0 may be set in VMX operation. They report on bits in CR0 that are allowed to be 0 and to be 1, respectively, in VMX operation. If bit X is 1 in IA32_VMX_CR0_FIXED0, then that bit of CR0 is fixed to 1 in VMX operation. Similarly, if bit X is 0 in IA32_VMX_CR0_FIXED1, then that bit of CR0 is fixed to 0 in VMX operation. It is always the case that, if bit X is 1 in IA32_VMX_CR0_FIXED0, then that bit is also 1 in IA32_VMX_CR0_FIXED1; if bit X is 0 in IA32_VMX_CR0_FIXED1, then that bit is also 0 in IA32_VMX_CR0_FIXED0. Thus, each bit in CR0 is either fixed to 0 (with value 0 in both MSRs), fixed to 1 (1 in both MSRs), or flexible (0 in IA32_VMX_CR0_FIXED0 and 1 in IA32_VMX_CR0_FIXED1).

## A.8 VMX-FIXED BITS IN CR4

The IA32_VMX_CR4_FIXED0 MSR (index 488H) and IA32_VMX_CR4_FIXED1 MSR (index 489H) indicate how bits in CR4 may be set in VMX operation. They report on bits in CR4 that are allowed to be 0 and 1, respectively, in VMX operation. If bit X is 1 in IA32_VMX_CR4_FIXED0, then that bit of CR4 is fixed to 1 in VMX operation. Similarly, if bit X is 0 in IA32_VMX_CR4_FIXED1, then that bit of CR4 is fixed to 0 in VMX operation. It is always the case that, if bit X is 1 in IA32_VMX_CR4_FIXED0, then that bit is also 1 in IA32_VMX_CR4_FIXED1; if bit X is 0 in IA32_VMX_CR4_FIXED1, then that bit is also 0 in IA32_VMX_CR4_FIXED0. Thus, each bit in CR4 is either fixed to 0 (with value 0 in both MSRs), fixed to 1 (1 in both MSRs), or flexible (0 in IA32_VMX_CR4_FIXED0 and 1 in IA32_VMX_CR4_FIXED1).

## A.9 VMCS ENUMERATION

The IA32_VMX_VMCS_ENUM MSR (index 48AH) provides information to assist software in enumerating fields in the VMCS.

As noted in Section 24.11.2, each field in the VMCS is associated with a 32-bit encoding which is structured as follows:

- Bits 31:15 are reserved (must be 0).
- Bits 14:13 indicate the field's width.
- Bit 12 is reserved (must be 0).
- Bits 11:10 indicate the field's type.
- Bits 9:1 is an index field that distinguishes different fields with the same width and type.
- Bit 0 indicates access type.

IA32_VMX_VMCS_ENUM indicates to software the highest index value used in the encoding of any field supported by the processor:

- Bits 9:1 contain the highest index value used for any VMCS encoding.
- Bit 0 and bits 63:10 are reserved and are read as 0.

## A.10 VPID AND EPT CAPABILITIES

The IA32_VMX_EPT_VPID_CAP MSR (index 48CH) reports information about the capabilities of the logical processor with regard to virtual-processor identifiers (VPIDs, Section 28.1) and extended page tables (EPT, Section 28.2):

- If bit 0 is read as 1, the logical processor allows software to configure EPT paging-structure entries in which bits 2:0 have value 100b (indicating an execute-only translation).
- Bit 6 indicates support for a page-walk length of 4.
- If bit 8 is read as 1, the logical processor allows software to configure the EPT paging-structure memory type to be uncacheable (UC); see Section 24.6.11.
- If bit 14 is read as 1, the logical processor allows software to configure the EPT paging-structure memory type to be write-back (WB).
- If bit 16 is read as 1, the logical processor allows software to configure a EPT PDE to map a 2-Mbyte page (by setting bit 7 in the EPT PDE).
- If bit 17 is read as 1, the logical processor allows software to configure a EPT PDPTE to map a 1-Gbyte page (by setting bit 7 in the EPT PDPTE).
- Support for the INVEPT instruction (see Chapter 30 and Section 28.3.3.1).
  - — If bit 20 is read as 1, the INVEPT instruction is supported.
  - — If bit 25 is read as 1, the single-context INVEPT type is supported.
  - — If bit 26 is read as 1, the all-context INVEPT type is supported.
- If bit 21 is read as 1, accessed and dirty flags for EPT are supported (see Section 28.2.4).
- Support for the INVVPID instruction (see Chapter 30 and Section 28.3.3.1).
  - — If bit 32 is read as 1, the INVVPID instruction is supported.
  - — If bit 40 is read as 1, the individual-address INVVPID type is supported.
  - — If bit 41 is read as 1, the single-context INVVPID type is supported.
  - — If bit 42 is read as 1, the all-context INVVPID type is supported.
  - — If bit 43 is read as 1, the single-context-retaining-globals INVVPID type is supported.
- Bits 5:1, bit 7, bits 13:9, bit 15, bits 19:18, bits 24:22, bits 31:27, bits 39:33, and bits 63:44 are reserved and are read as 0.

The IA32_VMX_EPT_VPID_CAP MSR exists only on processors that support the 1-setting of the "activate secondary controls" VM-execution control (only if bit 63 of the IA32_VMX_PROCBASED_CTLS MSR is 1) and that support either the 1-setting of the "enable EPT" VM-execution control (only if bit 33 of the IA32_VMX_PROCBASED_CTLS2 MSR is 1) or the 1-setting of the "enable VPID" VM-execution control (only if bit 37 of the IA32_VMX_PROCBASED_CTLS2 MSR is 1).

## A.11 VM FUNCTIONS

The IA32_VMX_VMFUNC MSR (index 491H) reports on the allowed settings of the VM-function controls (see Section 24.6.14). VM entry allows bit X of the VM-function controls to be 1 if bit X in the MSR is set to 1; if bit X in the MSR is cleared to 0, VM entry fails if bit X of the VM-function controls, the "activate secondary controls" primary processor-based VM-execution control, and the "enable VM functions" secondary processor-based VM-execution control are all 1.

The IA32_VMX_VMFUNC MSR exists only on processors that support the 1-setting of the "activate secondary controls" VM-execution control (only if bit 63 of the IA32_VMX_PROCBASED_CTLS MSR is 1) and the 1-setting of the "enable VM functions" secondary processor-based VM-execution control (only if bit 45 of the IA32_VMX_PROCBASED_CTLS2 MSR is 1).

# APPENDIX B
# FIELD ENCODING IN VMCS

Every component of the VMCS is encoded by a 32-bit field that can be used by VMREAD and VMWRITE. Section 24.11.2 describes the structure of the encoding space (the meanings of the bits in each 32-bit encoding).

This appendix enumerates all fields in the VMCS and their encodings. Fields are grouped by width (16-bit, 32-bit, etc.) and type (guest-state, host-state, etc.)

## B.1 16-BIT FIELDS

A value of 0 in bits 14:13 of an encoding indicates a 16-bit field. Only guest-state areas and the host-state area contain 16-bit fields. As noted in Section 24.11.2, each 16-bit field allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

### B.1.1 16-Bit Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-1 enumerates the 16-bit control fields.

**Table B-1. Encoding for 16-Bit Control Fields (0000_00xx_xxxx_xxx0B)**

| Field Name | Index | Encoding |
|---|---|---|
| Virtual-processor identifier (VPID)[1] | 000000000B | 00000000H |
| Posted-interrupt notification vector[2] | 000000001B | 00000002H |
| EPTP index[3] | 000000010B | 00000004H |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the "enable VPID" VM-execution control.
2. This field exists only on processors that support the 1-setting of the "process posted interrupts" VM-execution control.
3. This field exists only on processors that support the 1-setting of the "EPT-violation #VE" VM-execution control.

### B.1.2 16-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-2 enumerates 16-bit guest-state fields.

**Table B-2. Encodings for 16-Bit Guest-State Fields (0000_10xx_xxxx_xxx0B)**

| Field Name | Index | Encoding |
|---|---|---|
| Guest ES selector | 000000000B | 00000800H |
| Guest CS selector | 000000001B | 00000802H |
| Guest SS selector | 000000010B | 00000804H |
| Guest DS selector | 000000011B | 00000806H |
| Guest FS selector | 000000100B | 00000808H |
| Guest GS selector | 000000101B | 0000080AH |
| Guest LDTR selector | 000000110B | 0000080CH |
| Guest TR selector | 000000111B | 0000080EH |

Table B-2. Encodings for 16-Bit Guest-State Fields (0000_10xx_xxxx_xxx0B) (Contd.)

| Field Name | Index | Encoding |
|---|---|---|
| Guest interrupt status[1] | 000001000B | 00000810H |

NOTES:
1. This field exists only on processors that support the 1-setting of the "virtual-interrupt delivery" VM-execution control.

### B.1.3 16-Bit Host-State Fields

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-3 enumerates the 16-bit host-state fields.

Table B-3. Encodings for 16-Bit Host-State Fields (0000_11xx_xxxx_xxx0B)

| Field Name | Index | Encoding |
|---|---|---|
| Host ES selector | 000000000B | 00000C00H |
| Host CS selector | 000000001B | 00000C02H |
| Host SS selector | 000000010B | 00000C04H |
| Host DS selector | 000000011B | 00000C06H |
| Host FS selector | 000000100B | 00000C08H |
| Host GS selector | 000000101B | 00000C0AH |
| Host TR selector | 000000110B | 00000C0CH |

## B.2 64-BIT FIELDS

A value of 1 in bits 14:13 of an encoding indicates a 64-bit field. There are 64-bit fields only for controls and for guest state. As noted in Section 24.11.2, every 64-bit field has two encodings, which differ on bit 0, the access type. Thus, each such field has an even encoding for full access and an odd encoding for high access.

### B.2.1 64-Bit Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-4 enumerates the 64-bit control fields.

Table B-4. Encodings for 64-Bit Control Fields (0010_00xx_xxxx_xxxAb)

| Field Name | Index | Encoding |
|---|---|---|
| Address of I/O bitmap A (full) | 000000000B | 00002000H |
| Address of I/O bitmap A (high) | | 00002001H |
| Address of I/O bitmap B (full) | 000000001B | 00002002H |
| Address of I/O bitmap B (high) | | 00002003H |
| Address of MSR bitmaps (full)[1] | 000000010B | 00002004H |
| Address of MSR bitmaps (high)[1] | | 00002005H |
| VM-exit MSR-store address (full) | 000000011B | 00002006H |
| VM-exit MSR-store address (high) | | 00002007H |
| VM-exit MSR-load address (full) | 000000100B | 00002008H |
| VM-exit MSR-load address (high) | | 00002009H |

Table B-4. Encodings for 64-Bit Control Fields (0010_00xx_xxxx_xxxAb) (Contd.)

| Field Name | Index | Encoding |
|---|---|---|
| VM-entry MSR-load address (full) | 000000101B | 0000200AH |
| VM-entry MSR-load address (high) | | 0000200BH |
| Executive-VMCS pointer (full) | 000000110B | 0000200CH |
| Executive-VMCS pointer (high) | | 0000200DH |
| TSC offset (full) | 000001000B | 00002010H |
| TSC offset (high) | | 00002011H |
| Virtual-APIC address (full)[2] | 000001001B | 00002012H |
| Virtual-APIC address (high)[2] | | 00002013H |
| APIC-access address (full)[3] | 000001010B | 00002014H |
| APIC-access address (high)[3] | | 00002015H |
| Posted-interrupt descriptor address (full)[4] | 000001011B | 00002016H |
| Posted-interrupt descriptor address (high)[4] | | 00002017H |
| VM-function controls (full)[5] | 000001100B | 00002018H |
| VM-function controls (high)[5] | | 00002019H |
| EPT pointer (EPTP; full)[6] | 000001101B | 0000201AH |
| EPT pointer (EPTP; high)[6] | | 0000201BH |
| EOI-exit bitmap 0 (EOI_EXIT0; full)[7] | 000001110B | 0000201CH |
| EOI-exit bitmap 0 (EOI_EXIT0; high)[7] | | 0000201DH |
| EOI-exit bitmap 1 (EOI_EXIT1; full)[7] | 000001111B | 0000201EH |
| EOI-exit bitmap 1 (EOI_EXIT1; high)[7] | | 0000201FH |
| EOI-exit bitmap 2 (EOI_EXIT2; full)[7] | 000010000B | 00002020H |
| EOI-exit bitmap 2 (EOI_EXIT2; high)[7] | | 00002021H |
| EOI-exit bitmap 3 (EOI_EXIT3; full)[7] | 000010001B | 00002022H |
| EOI-exit bitmap 3 (EOI_EXIT3; high)[7] | | 00002023H |
| EPTP-list address (full)[8] | 000010010B | 00002024H |
| EPTP-list address (high)[8] | | 00002025H |
| VMREAD-bitmap address (full)[9] | 000010011B | 00002026H |
| VMREAD-bitmap address (high)[9] | | 00002027H |
| VMWRITE-bitmap address (full)[9] | 000010100B | 00002028H |
| VMWRITE-bitmap address (high)[9] | | 00002029H |
| Virtualization-exception information address (full)[10] | 000010101B | 0000202AH |
| Virtualization-exception information address (high)[10] | | 0000202BH |
| XSS-exiting bitmap (full)[11] | 000010110B | 0000202CH |
| XSS-exiting bitmap (high)[11] | | 0000202DH |

NOTES:

1. This field exists only on processors that support the 1-setting of the "use MSR bitmaps" VM-execution control.
2. This field exists only on processors that support either the 1-setting of the "use TPR shadow" VM-execution control.
3. This field exists only on processors that support the 1-setting of the "virtualize APIC accesses" VM-execution control.

4. This field exists only on processors that support the 1-setting of the "process posted interrupts" VM-execution control.
5. This field exists only on processors that support the 1-setting of the "enable VM functions" VM-execution control.
6. This field exists only on processors that support the 1-setting of the "enable EPT" VM-execution control.
7. This field exists only on processors that support the 1-setting of the "virtual-interrupt delivery" VM-execution control.
8. This field exists only on processors that support the 1-setting of the "EPTP switching" VM-function control.
9. This field exists only on processors that support the 1-setting of the "VMCS shadowing" VM-execution control.
10. This field exists only on processors that support the 1-setting of the "EPT-violation #VE" VM-execution control.
11. This field exists only on processors that support the 1-setting of the "enable XSAVES/XRSTORS" VM-execution control.

### B.2.2 64-Bit Read-Only Data Field

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. There is only one such 64-bit field as given in Table B-5.(As with other 64-bit fields, this one has two encodings.)

**Table B-5. Encodings for 64-Bit Read-Only Data Field (0010_01xx_xxxx_xxxAb)**

| Field Name | Index | Encoding |
|---|---|---|
| Guest-physical address (full)[1] | 000000000B | 00002400H |
| Guest-physical address (high)[1] | | 00002401H |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the "enable EPT" VM-execution control.

### B.2.3 64-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-6 enumerates the 64-bit guest-state fields.

**Table B-6. Encodings for 64-Bit Guest-State Fields (0010_10xx_xxxx_xxxAb)**

| Field Name | Index | Encoding |
|---|---|---|
| VMCS link pointer (full) | 000000000B | 00002800H |
| VMCS link pointer (high) | | 00002801H |
| Guest IA32_DEBUGCTL (full) | 000000001B | 00002802H |
| Guest IA32_DEBUGCTL (high) | | 00002803H |
| Guest IA32_PAT (full)[1] | 000000010B | 00002804H |
| Guest IA32_PAT (high)[1] | | 00002805H |
| Guest IA32_EFER (full)[2] | 000000011B | 00002806H |
| Guest IA32_EFER (high)[2] | | 00002807H |
| Guest IA32_PERF_GLOBAL_CTRL (full)[3] | 000000100B | 00002808H |
| Guest IA32_PERF_GLOBAL_CTRL (high)[3] | | 00002809H |
| Guest PDPTE0 (full)[4] | 000000101B | 0000280AH |
| Guest PDPTE0 (high)[4] | | 0000280BH |
| Guest PDPTE1 (full)[4] | 000000110B | 0000280CH |
| Guest PDPTE1 (high)[4] | | 0000280DH |
| Guest PDPTE2 (full)[4] | 000000111B | 0000280EH |
| Guest PDPTE2 (high)[4] | | 0000280FH |

Table B-6. Encodings for 64-Bit Guest-State Fields (0010_10xx_xxxx_xxxAb) (Contd.)

| Field Name | Index | Encoding |
|---|---|---|
| Guest PDPTE3 (full)[4] | 000001000B | 00002810H |
| Guest PDPTE3 (high)[4] | | 00002811H |

NOTES:

1. This field exists only on processors that support either the 1-setting of the "load IA32_PAT" VM-entry control or that of the "save IA32_PAT" VM-exit control.
2. This field exists only on processors that support either the 1-setting of the "load IA32_EFER" VM-entry control or that of the "save IA32_EFER" VM-exit control.
3. This field exists only on processors that support the 1-setting of the "load IA32_PERF_GLOBAL_CTRL" VM-entry control.
4. This field exists only on processors that support the 1-setting of the "enable EPT" VM-execution control.

### B.2.4 64-Bit Host-State Fields

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-7 enumerates the 64-bit control fields.

Table B-7. Encodings for 64-Bit Host-State Fields (0010_11xx_xxxx_xxxAb)

| Field Name | Index | Encoding |
|---|---|---|
| Host IA32_PAT (full)[1] | 000000000B | 00002C00H |
| Host IA32_PAT (high)[1] | | 00002C01H |
| Host IA32_EFER (full)[2] | 000000001B | 00002C02H |
| Host IA32_EFER (high)[2] | | 00002C03H |
| Host IA32_PERF_GLOBAL_CTRL (full)[3] | 000000010B | 00002C04H |
| Host IA32_PERF_GLOBAL_CTRL (high)[3] | | 00002C05H |

NOTES:

1. This field exists only on processors that support the 1-setting of the "load IA32_PAT" VM-exit control.
2. This field exists only on processors that support the 1-setting of the "load IA32_EFER" VM-exit control.
3. This field exists only on processors that support the 1-setting of the "load IA32_PERF_GLOBAL_CTRL" VM-exit control.

## B.3 32-BIT FIELDS

A value of 2 in bits 14:13 of an encoding indicates a 32-bit field. As noted in Section 24.11.2, each 32-bit field allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

### B.3.1 32-Bit Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-8 enumerates the 32-bit control fields.

Table B-8. Encodings for 32-Bit Control Fields (0100_00xx_xxxx_xxx0B)

| Field Name | Index | Encoding |
|---|---|---|
| Pin-based VM-execution controls | 000000000B | 00004000H |
| Primary processor-based VM-execution controls | 000000001B | 00004002H |
| Exception bitmap | 000000010B | 00004004H |
| Page-fault error-code mask | 000000011B | 00004006H |

Table B-8. Encodings for 32-Bit Control Fields (0100_00xx_xxxx_xxx0B) (Contd.)

| Field Name | Index | Encoding |
|---|---|---|
| Page-fault error-code match | 000000100B | 00004008H |
| CR3-target count | 000000101B | 0000400AH |
| VM-exit controls | 000000110B | 0000400CH |
| VM-exit MSR-store count | 000000111B | 0000400EH |
| VM-exit MSR-load count | 000001000B | 00004010H |
| VM-entry controls | 000001001B | 00004012H |
| VM-entry MSR-load count | 000001010B | 00004014H |
| VM-entry interruption-information field | 000001011B | 00004016H |
| VM-entry exception error code | 000001100B | 00004018H |
| VM-entry instruction length | 000001101B | 0000401AH |
| TPR threshold[1] | 000001110B | 0000401CH |
| Secondary processor-based VM-execution controls[2] | 000001111b | 0000401EH |
| PLE_Gap[3] | 000010000b | 00004020H |
| PLE_Window[3] | 000010001b | 00004022H |

NOTES:

1. This field exists only on processors that support the 1-setting of the "use TPR shadow" VM-execution control.
2. This field exists only on processors that support the 1-setting of the "activate secondary controls" VM-execution control.
3. This field exists only on processors that support the 1-setting of the "PAUSE-loop exiting" VM-execution control.

## B.3.2 32-Bit Read-Only Data Fields

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. Table B-9 enumerates the 32-bit read-only data fields.

Table B-9. Encodings for 32-Bit Read-Only Data Fields (0100_01xx_xxxx_xxx0B)

| Field Name | Index | Encoding |
|---|---|---|
| VM-instruction error | 000000000B | 00004400H |
| Exit reason | 000000001B | 00004402H |
| VM-exit interruption information | 000000010B | 00004404H |
| VM-exit interruption error code | 000000011B | 00004406H |
| IDT-vectoring information field | 000000100B | 00004408H |
| IDT-vectoring error code | 000000101B | 0000440AH |
| VM-exit instruction length | 000000110B | 0000440CH |
| VM-exit instruction information | 000000111B | 0000440EH |

### B.3.3 32-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-10 enumerates the 32-bit guest-state fields.

**Table B-10. Encodings for 32-Bit Guest-State Fields (0100_10xx_xxxx_xxx0B)**

| Field Name | Index | Encoding |
|---|---|---|
| Guest ES limit | 000000000B | 00004800H |
| Guest CS limit | 000000001B | 00004802H |
| Guest SS limit | 000000010B | 00004804H |
| Guest DS limit | 000000011B | 00004806H |
| Guest FS limit | 000000100B | 00004808H |
| Guest GS limit | 000000101B | 0000480AH |
| Guest LDTR limit | 000000110B | 0000480CH |
| Guest TR limit | 000000111B | 0000480EH |
| Guest GDTR limit | 000001000B | 00004810H |
| Guest IDTR limit | 000001001B | 00004812H |
| Guest ES access rights | 000001010B | 00004814H |
| Guest CS access rights | 000001011B | 00004816H |
| Guest SS access rights | 000001100B | 00004818H |
| Guest DS access rights | 000001101B | 0000481AH |
| Guest FS access rights | 000001110B | 0000481CH |
| Guest GS access rights | 000001111B | 0000481EH |
| Guest LDTR access rights | 000010000B | 00004820H |
| Guest TR access rights | 000010001B | 00004822H |
| Guest interruptibility state | 000010010B | 00004824H |
| Guest activity state | 000010011B | 00004826H |
| Guest SMBASE | 000010100B | 00004828H |
| Guest IA32_SYSENTER_CS | 000010101B | 0000482AH |
| VMX-preemption timer value[1] | 000010111B | 0000482EH |

**NOTES:**

1. This field exists only on processors that support the 1-setting of the "activate VMX-preemption timer" VM-execution control.

The limit fields for GDTR and IDTR are defined to be 32 bits in width even though these fields are only 16-bits wide in the Intel 64 and IA-32 architectures. VM entry ensures that the high 16 bits of both these fields are cleared to 0.

### B.3.4 32-Bit Host-State Field

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. There is only one such 32-bit field as given in Table B-11.

**Table B-11. Encoding for 32-Bit Host-State Field (0100_11xx_xxxx_xxx0B)**

| Field Name | Index | Encoding |
|---|---|---|
| Host IA32_SYSENTER_CS | 000000000B | 00004C00H |

## B.4 NATURAL-WIDTH FIELDS

A value of 3 in bits 14:13 of an encoding indicates a natural-width field. As noted in Section 24.11.2, each of these fields allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

### B.4.1 Natural-Width Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-12 enumerates the natural-width control fields.

**Table B-12. Encodings for Natural-Width Control Fields (0110_00xx_xxxx_xxx0B)**

| Field Name | Index | Encoding |
|---|---|---|
| CR0 guest/host mask | 000000000B | 00006000H |
| CR4 guest/host mask | 000000001B | 00006002H |
| CR0 read shadow | 000000010B | 00006004H |
| CR4 read shadow | 000000011B | 00006006H |
| CR3-target value 0 | 000000100B | 00006008H |
| CR3-target value 1 | 000000101B | 0000600AH |
| CR3-target value 2 | 000000110B | 0000600CH |
| CR3-target value 3[1] | 000000111B | 0000600EH |

NOTES:

1. If a future implementation supports more than 4 CR3-target values, they will be encoded consecutively following the 4 encodings given here.

### B.4.2 Natural-Width Read-Only Data Fields

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. Table B-13 enumerates the natural-width read-only data fields.

**Table B-13. Encodings for Natural-Width Read-Only Data Fields (0110_01xx_xxxx_xxx0B)**

| Field Name | Index | Encoding |
|---|---|---|
| Exit qualification | 000000000B | 00006400H |
| I/O RCX | 000000001B | 00006402H |
| I/O RSI | 000000010B | 00006404H |
| I/O RDI | 000000011B | 00006406H |
| I/O RIP | 000000100B | 00006408H |
| Guest-linear address | 000000101B | 0000640AH |

### B.4.3 Natural-Width Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-14 enumerates the natural-width guest-state fields.

Table B-14. Encodings for Natural-Width Guest-State Fields (0110_10xx_xxxx_xxx0B)

| Field Name | Index | Encoding |
|---|---|---|
| Guest CR0 | 000000000B | 00006800H |
| Guest CR3 | 000000001B | 00006802H |
| Guest CR4 | 000000010B | 00006804H |
| Guest ES base | 000000011B | 00006806H |
| Guest CS base | 000000100B | 00006808H |
| Guest SS base | 000000101B | 0000680AH |
| Guest DS base | 000000110B | 0000680CH |
| Guest FS base | 000000111B | 0000680EH |
| Guest GS base | 000001000B | 00006810H |
| Guest LDTR base | 000001001B | 00006812H |
| Guest TR base | 000001010B | 00006814H |
| Guest GDTR base | 000001011B | 00006816H |
| Guest IDTR base | 000001100B | 00006818H |
| Guest DR7 | 000001101B | 0000681AH |
| Guest RSP | 000001110B | 0000681CH |
| Guest RIP | 000001111B | 0000681EH |
| Guest RFLAGS | 000010000B | 00006820H |
| Guest pending debug exceptions | 000010001B | 00006822H |
| Guest IA32_SYSENTER_ESP | 000010010B | 00006824H |
| Guest IA32_SYSENTER_EIP | 000010011B | 00006826H |

The base-address fields for ES, CS, SS, and DS in the guest-state area are defined to be natural-width (with 64 bits on processors supporting Intel 64 architecture) even though these fields are only 32-bits wide in the Intel 64 architecture. VM entry ensures that the high 32 bits of these fields are cleared to 0.

### B.4.4 Natural-Width Host-State Fields

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-15 enumerates the natural-width host-state fields.

Table B-15. Encodings for Natural-Width Host-State Fields (0110_11xx_xxxx_xxx0B)

| Field Name | Index | Encoding |
|---|---|---|

# APPENDIX C
# VMX BASIC EXIT REASONS

Every VM exit writes a 32-bit exit reason to the VMCS (see Section 24.9.1). Certain VM-entry failures also do this (see Section 26.7). The low 16 bits of the exit-reason field form the basic exit reason which provides basic information about the cause of the VM exit or VM-entry failure.

Table C-1 lists values for basic exit reasons and explains their meaning. Entries apply to VM exits, unless otherwise noted.

**Table C-1. Basic Exit Reasons**

| Basic Exit Reason | Description |
|---|---|
| 0 | **Exception or non-maskable interrupt (NMI).** Either:<br>1: Guest software caused an exception and the bit in the exception bitmap associated with exception's vector was 1.<br>2: An NMI was delivered to the logical processor and the "NMI exiting" VM-execution control was 1. This case includes executions of BOUND that cause #BR, executions of INT3 (they cause #BP), executions of INTO that cause #OF, and executions of UD2 (they cause #UD). |
| 1 | **External interrupt.** An external interrupt arrived and the "external-interrupt exiting" VM-execution control was 1. |
| 2 | **Triple fault.** The logical processor encountered an exception while attempting to call the double-fault handler and that exception did not itself cause a VM exit due to the exception bitmap. |
| 3 | **INIT signal.** An INIT signal arrived |
| 4 | **Start-up IPI (SIPI).** A SIPI arrived while the logical processor was in the "wait-for-SIPI" state. |
| 5 | **I/O system-management interrupt (SMI).** An SMI arrived immediately after retirement of an I/O instruction and caused an SMM VM exit (see Section 34.15.2). |
| 6 | **Other SMI.** An SMI arrived and caused an SMM VM exit (see Section 34.15.2) but not immediately after retirement of an I/O instruction. |
| 7 | **Interrupt window.** At the beginning of an instruction, RFLAGS.IF was 1; events were not blocked by STI or by MOV SS; and the "interrupt-window exiting" VM-execution control was 1. |
| 8 | **NMI window.** At the beginning of an instruction, there was no virtual-NMI blocking; events were not blocked by MOV SS; and the "NMI-window exiting" VM-execution control was 1. |
| 9 | **Task switch.** Guest software attempted a task switch. |
| 10 | **CPUID.** Guest software attempted to execute CPUID. |
| 11 | **GETSEC.** Guest software attempted to execute GETSEC. |
| 12 | **HLT.** Guest software attempted to execute HLT and the "HLT exiting" VM-execution control was 1. |
| 13 | **INVD.** Guest software attempted to execute INVD. |
| 14 | **INVLPG.** Guest software attempted to execute INVLPG and the "INVLPG exiting" VM-execution control was 1. |
| 15 | **RDPMC.** Guest software attempted to execute RDPMC and the "RDPMC exiting" VM-execution control was 1. |
| 16 | **RDTSC.** Guest software attempted to execute RDTSC and the "RDTSC exiting" VM-execution control was 1. |
| 17 | **RSM.** Guest software attempted to execute RSM in SMM. |
| 18 | **VMCALL.** VMCALL was executed either by guest software (causing an ordinary VM exit) or by the executive monitor (causing an SMM VM exit; see Section 34.15.2). |
| 19 | **VMCLEAR.** Guest software attempted to execute VMCLEAR. |
| 20 | **VMLAUNCH.** Guest software attempted to execute VMLAUNCH. |
| 21 | **VMPTRLD.** Guest software attempted to execute VMPTRLD. |
| 22 | **VMPTRST.** Guest software attempted to execute VMPTRST. |
| 23 | **VMREAD.** Guest software attempted to execute VMREAD. |

**Table C-1. Basic Exit Reasons (Contd.)**

| Basic Exit Reason | Description |
|---|---|
| 24 | **VMRESUME.** Guest software attempted to execute VMRESUME. |
| 25 | **VMWRITE.** Guest software attempted to execute VMWRITE. |
| 26 | **VMXOFF.** Guest software attempted to execute VMXOFF. |
| 27 | **VMXON.** Guest software attempted to execute VMXON. |
| 28 | **Control-register accesses.** Guest software attempted to access CR0, CR3, CR4, or CR8 using CLTS, LMSW, or MOV CR and the VM-execution control fields indicate that a VM exit should occur (see Section 25.1 for details). This basic exit reason is not used for trap-like VM exits following executions of the MOV to CR8 instruction when the "use TPR shadow" VM-execution control is 1. |
| 29 | **MOV DR.** Guest software attempted a MOV to or from a debug register and the "MOV-DR exiting" VM-execution control was 1. |
| 30 | **I/O instruction.** Guest software attempted to execute an I/O instruction and either:<br>1: The "use I/O bitmaps" VM-execution control was 0 and the "unconditional I/O exiting" VM-execution control was 1.<br>2: The "use I/O bitmaps" VM-execution control was 1 and a bit in the I/O bitmap associated with one of the ports accessed by the I/O instruction was 1. |
| 31 | **RDMSR.** Guest software attempted to execute RDMSR and either:<br>1: The "use MSR bitmaps" VM-execution control was 0.<br>2: The value of RCX is neither in the range 00000000H – 00001FFFH nor in the range C0000000H – C0001FFFH.<br>3: The value of RCX was in the range 00000000H – 00001FFFH and the $n^{th}$ bit in read bitmap for low MSRs is 1, where $n$ was the value of RCX.<br>4: The value of RCX is in the range C0000000H – C0001FFFH and the $n^{th}$ bit in read bitmap for high MSRs is 1, where $n$ is the value of RCX & 00001FFFH. |
| 32 | **WRMSR.** Guest software attempted to execute WRMSR and either:<br>1: The "use MSR bitmaps" VM-execution control was 0.<br>2: The value of RCX is neither in the range 00000000H – 00001FFFH nor in the range C0000000H – C0001FFFH.<br>3: The value of RCX was in the range 00000000H – 00001FFFH and the $n^{th}$ bit in write bitmap for low MSRs is 1, where $n$ was the value of RCX.<br>4: The value of RCX is in the range C0000000H – C0001FFFH and the $n^{th}$ bit in write bitmap for high MSRs is 1, where $n$ is the value of RCX & 00001FFFH. |
| 33 | **VM-entry failure due to invalid guest state.** A VM entry failed one of the checks identified in Section 26.3.1. |
| 34 | **VM-entry failure due to MSR loading.** A VM entry failed in an attempt to load MSRs. See Section 26.4. |
| 36 | **MWAIT.** Guest software attempted to execute MWAIT and the "MWAIT exiting" VM-execution control was 1. |
| 37 | **Monitor trap flag.** A VM entry occurred due to the 1-setting of the "monitor trap flag" VM-execution control and injection of an MTF VM exit as part of VM entry. See Section 25.5.2. |
| 39 | **MONITOR.** Guest software attempted to execute MONITOR and the "MONITOR exiting" VM-execution control was 1. |
| 40 | **PAUSE.** Either guest software attempted to execute PAUSE and the "PAUSE exiting" VM-execution control was 1 or the "PAUSE-loop exiting" VM-execution control was 1 and guest software executed a PAUSE loop with execution time exceeding PLE_Window (see Section 25.1.3). |
| 41 | **VM-entry failure due to machine-check event.** A machine-check event occurred during VM entry (see Section 26.8). |
| 43 | **TPR below threshold.** The logical processor determined that the value of bits 7:4 of the byte at offset 080H on the virtual-APIC page was below that of the TPR threshold VM-execution control field while the "use TPR shadow" VM-execution control was 1 either as part of TPR virtualization (Section 29.1.2) or VM entry (Section 26.6.7). |
| 44 | **APIC access.** Guest software attempted to access memory at a physical address on the APIC-access page and the "virtualize APIC accesses" VM-execution control was 1 (see Section 29.4). |
| 45 | **Virtualized EOI.** EOI virtualization was performed for a virtual interrupt whose vector indexed a bit set in the EOI-exit bitmap. |

Table C-1. Basic Exit Reasons (Contd.)

| Basic Exit Reason | Description |
|---|---|
| 46 | **Access to GDTR or IDTR.** Guest software attempted to execute LGDT, LIDT, SGDT, or SIDT and the "descriptor-table exiting" VM-execution control was 1. |
| 47 | **Access to LDTR or TR.** Guest software attempted to execute LLDT, LTR, SLDT, or STR and the "descriptor-table exiting" VM-execution control was 1. |
| 48 | **EPT violation.** An attempt to access memory with a guest-physical address was disallowed by the configuration of the EPT paging structures. |
| 49 | **EPT misconfiguration.** An attempt to access memory with a guest-physical address encountered a misconfigured EPT paging-structure entry. |
| 50 | **INVEPT.** Guest software attempted to execute INVEPT. |
| 51 | **RDTSCP.** Guest software attempted to execute RDTSCP and the "enable RDTSCP" and "RDTSC exiting" VM-execution controls were both 1. |
| 52 | **VMX-preemption timer expired.** The preemption timer counted down to zero. |
| 53 | **INVVPID.** Guest software attempted to execute INVVPID. |
| 54 | **WBINVD.** Guest software attempted to execute WBINVD and the "WBINVD exiting" VM-execution control was 1. |
| 55 | **XSETBV.** Guest software attempted to execute XSETBV. |
| 56 | **APIC write.** Guest software completed a write to the virtual-APIC page that must be virtualized by VMM software (see Section 29.4.3.3). |
| 57 | **RDRAND.** Guest software attempted to execute RDRAND and the "RDRAND exiting" VM-execution control was 1. |
| 58 | **INVPCID.** Guest software attempted to execute INVPCID and the "enable INVPCID" and "INVLPG exiting" VM-execution controls were both 1. |
| 59 | **VMFUNC.** Guest software invoked a VM function with the VMFUNC instruction and the VM function either was not enabled or generated a function-specific condition causing a VM exit. |
| 61 | **RDSEED.** Guest software attempted to execute RDSEED and the "RDSEED exiting" VM-execution control was 1. |
| 63 | **XSAVES.** Guest software attempted to execute XSAVES, the "enable XSAVES/XRSTORS" was 1, and a bit was set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap. |
| 64 | **XRSTORS.** Guest software attempted to execute XRSTORS, the "enable XSAVES/XRSTORS" was 1, and a bit was set in the logical-AND of the following three values: EDX:EAX, the IA32_XSS MSR, and the XSS-exiting bitmap. |

counting, Vol.3-18-15, Vol.3-18-16, Vol.3-18-72
events, Vol.3-18-15, Vol.3-18-16, Vol.3-18-62, Vol.3-18-63, Vol.3-18-72, Vol.3-18-77
authenticated code execution mode, Vol.2-5-3
Auto HALT restart
field, SMM, Vol.3-34-14
SMM, Vol.3-34-13
Automatic bus locking, Vol.3-8-3

Automatic thermal monitoring mechanism, Vol.3-14-20
AX register, Vol.1-3-11

## B

B (busy) flag
TSS descriptor, Vol.3-7-5, Vol.3-7-10, Vol.3-7-13, Vol.3-8-3
B (default size) flag, segment descriptor, Vol.1-3-17
B (default stack size) flag
segment descriptor, Vol.3-21-1, Vol.3-22-32
B0-B3 (BP condition detected) flags
DR6 register, Vol.3-17-3
Backlink (see Previous task link)
Base address fields, segment descriptor, Vol.3-3-10
Base (operand addressing), Vol.1-3-21, Vol.1-3-22, Vol.1-3-23, Vol.2-2-3
Basic execution environment, Vol.1-3-2
Basic programming environment, Vol.1-7-1
B-bit, x87 FPU status word, Vol.1-8-5
BCD integers
packed, Vol.1-4-10, Vol.2-3-232, Vol.2-3-234, Vol.2-3-266, Vol.2-3-268
relationship to status flags, Vol.1-3-16
unpacked, Vol.1-4-9, Vol.1-7-9, Vol.2-3-16, Vol.2-3-18, Vol.2-3-20, Vol.2-3-22
x87 FPU encoding, Vol.1-4-10
BD (debug register access detected) flag, DR6 register, Vol.3-17-3, Vol.3-17-9
BEXTR - Bit Field Extract, Vol.2-3-70
BH register, Vol.1-3-11
Bias value
numeric overflow, Vol.1-8-28
numeric underflow, Vol.1-8-29
Biased exponent, Vol.1-4-13
Biasing constant, for floating-point numbers, Vol.1-4-6
Binary numbers, Vol.1-1-6, Vol.2-1-5, Vol.3-1-7
Binary-coded decimal (see BCD)
BINIT# signal, Vol.3-2-23
BIOS role in microcode updates, Vol.3-9-38
Bit field, Vol.1-4-7
Bit order, Vol.1-1-4, Vol.2-1-4, Vol.3-1-5
BL register, Vol.1-3-11
BLSMSK - Get Mask Up to Lowest Set Bit, Vol.2-3-80
bootstrap processor, Vol.2-5-15, Vol.2-5-20, Vol.2-5-28, Vol.2-5-29
BOUND instruction, Vol.1-6-12, Vol.1-7-18, Vol.1-7-23, Vol.2-3-82, Vol.2-4-432, Vol.3-2-5, Vol.3-6-4, Vol.3-6-25
BOUND range exceeded exception (#BR), Vol.1-6-13, Vol.2-3-82, Vol.2-4-432, Vol.3-6-25
BP register, Vol.1-3-11
BP0#, BP1#, BP2#, and BP3# pins, Vol.3-17-33, Vol.3-17-35
Branch
control transfer instructions, Vol.1-7-14
hints, Vol.1-11-13
on EFLAGS register status flags, Vol.1-7-15, Vol.1-8-6
on x87 FPU condition codes, Vol.1-8-6, Vol.1-8-19
prediction, Vol.1-2-8
Branch hints, Vol.2-2-2
Branch record
branch trace message, Vol.3-17-13
IA-32e mode, Vol.3-17-19
saving, Vol.3-17-14, Vol.3-17-23, Vol.3-17-30
saving as a branch trace message, Vol.3-17-13
structure, Vol.3-17-30
structure of in BTS buffer, Vol.3-17-18
Branch trace message (see BTM)
Branch trace store (see BTS)
Brand information, Vol.2-3-183
processor brand index, Vol.2-3-186
processor brand string, Vol.2-3-184
Breakpoint exception (#BP), Vol.3-6-4, Vol.3-6-23, Vol.3-17-10
Breakpoints
data breakpoint, Vol.3-17-5
data breakpoint exception conditions, Vol.3-17-9
description of, Vol.3-17-1
DR0-DR3 debug registers, Vol.3-17-3
example, Vol.3-17-5
exception, Vol.3-6-23
field recognition, Vol.3-17-5, Vol.3-17-6
general-detect exception condition, Vol.3-17-9
instruction breakpoint, Vol.3-17-5
instruction breakpoint exception condition, Vol.3-17-8
I/O breakpoint exception conditions, Vol.3-17-9
LEN0 - LEN3 (Length) fields
DR7 register, Vol.3-17-5
R/W0-R/W3 (read/write) fields
DR7 register, Vol.3-17-4
single-step exception condition, Vol.3-17-9
task-switch exception condition, Vol.3-17-10
BS (single step) flag, DR6 register, Vol.3-17-3
BSF instruction, Vol.1-7-14, Vol.2-3-84
BSP flag, IA32_APIC_BASE MSR, Vol.3-10-8
BSR instruction, Vol.1-7-14, Vol.2-3-86
BSWAP instruction, Vol.1-7-4, Vol.2-3-88, Vol.3-22-4
BT instruction, Vol.1-3-14, Vol.1-3-15, Vol.1-7-14, Vol.2-3-89
BT (task switch) flag, DR6 register, Vol.3-17-3, Vol.3-17-10
BTC instruction, Vol.1-3-14, Vol.1-3-15, Vol.1-7-14, Vol.2-3-91, Vol.2-3-472, Vol.3-8-3
BTF (single-step on branches) flag
DEBUGCTLMSR MSR, Vol.3-17-35
BTMs (branch trace messages)
description of, Vol.3-17-13
enabling, Vol.3-17-11, Vol.3-17-21, Vol.3-17-22, Vol.3-17-29, Vol.3-17-32, Vol.3-17-33
TR (trace message enable) flag
MSR_DEBUGCTLA MSR, Vol.3-17-29
MSR_DEBUGCTLB MSR, Vol.3-17-11, Vol.3-17-32, Vol.3-17-33
BTR instruction, Vol.1-3-14, Vol.1-3-15, Vol.1-7-14, Vol.2-3-93, Vol.2-3-472, Vol.3-8-3
BTS buffer
description of, Vol.3-17-16
introduction to, Vol.3-17-11, Vol.3-17-13
records in, Vol.3-17-18
setting up, Vol.3-17-21
structure of, Vol.3-17-17, Vol.3-17-19, Vol.3-18-27
BTS instruction, Vol.1-3-14, Vol.1-3-15, Vol.1-7-14, Vol.2-3-95, Vol.2-3-472, Vol.3-8-3
BTS (branch trace store) facilities
availability of, Vol.3-17-28
BTS_UNAVAILABLE flag, IA32_MISC_ENABLE MSR, Vol.3-17-16, Vol.1-35-178
introduction to, Vol.3-17-11
setting up BTS buffer, Vol.3-17-21
writing an interrupt service routine for, Vol.3-17-22
BTS_UNAVAILABLE, Vol.3-17-16
Built-in self-test (BIST)
description of, Vol.3-9-1
performing, Vol.3-9-2
Bus
errors detected with MCA, Vol.3-15-26
hold, Vol.3-22-34
locking, Vol.3-8-3, Vol.3-22-34
BX register, Vol.1-3-11
Byte, Vol.1-4-1
Byte order, Vol.1-1-4, Vol.2-1-4, Vol.3-1-5

## C

C (conforming) flag, segment descriptor, Vol.3-5-11
C1 flag, x87 FPU status word, Vol.1-8-4, Vol.1-8-26, Vol.1-8-28, Vol.1-8-29, Vol.3-22-7, Vol.3-22-14
C2 flag, x87 FPU status word, Vol.1-8-5, Vol.3-22-7
Cache and TLB information, Vol.2-3-178
Cache control, Vol.3-11-20
adaptive mode, L1 Data Cache, Vol.3-11-18
cache management instructions, Vol.3-11-17, Vol.3-11-18

cache mechanisms in IA-32 processors, Vol.3-22-29
caching terminology, Vol.3-11-5
CD flag, CR0 control register, Vol.3-11-10, Vol.3-22-18
choosing a memory type, Vol.3-11-8
CPUID feature flag, Vol.3-11-18
flags and fields, Vol.3-11-10
flushing TLBs, Vol.3-11-19
G (global) flag
page-directory entries, Vol.3-11-13
page-table entries, Vol.3-11-13
internal caches, Vol.3-11-1
MemTypeGet() function, Vol.3-11-29
MemTypeSet() function, Vol.3-11-31
MESI protocol, Vol.3-11-5, Vol.3-11-9
methods of caching available, Vol.3-11-6
MTRR initialization, Vol.3-11-29
MTRR precedences, Vol.3-11-28
MTRRs, description of, Vol.3-11-20
multiple-processor considerations, Vol.3-11-32
NW flag, CR0 control register, Vol.3-11-13, Vol.3-22-18
operating modes, Vol.3-11-12
overview of, Vol.3-11-1
page attribute table (PAT), Vol.3-11-33
PCD flag
CR3 control register, Vol.3-11-13
page-directory entries, Vol.3-11-13, Vol.3-11-33
page-table entries, Vol.3-11-13, Vol.3-11-33
PGE (page global enable) flag, CR4 control register, Vol.3-11-13
precedence of controls, Vol.3-11-13
preventing caching, Vol.3-11-16
protocol, Vol.3-11-9
PWT flag
CR3 control register, Vol.3-11-13
page-directory entries, Vol.3-11-33
page-table entries, Vol.3-11-33
remapping memory types, Vol.3-11-29
setting up memory ranges with MTRRs, Vol.3-11-22
shared mode, L1 Data Cache, Vol.3-11-18
variable-range MTRRs, Vol.3-11-23, Vol.3-11-25
Cache Inclusiveness, Vol.2-3-164
Caches, Vol.3-2-7
cache hit, Vol.3-11-5
cache line, Vol.3-11-5
cache line fill, Vol.3-11-5
cache write hit, Vol.3-11-5
description of, Vol.3-11-1
effects of a locked operation on internal processor caches, Vol.3-8-5
enabling, Vol.3-9-7
management, instructions, Vol.3-2-22, Vol.3-11-17
Caches, invalidating (flushing), Vol.2-3-420, Vol.2-4-555
cache, smart, Vol.1-2-4
Caching
cache control protocol, Vol.3-11-9
cache line, Vol.3-11-5
cache management instructions, Vol.3-11-17
cache mechanisms in IA-32 processors, Vol.3-22-29
caching terminology, Vol.3-11-5
choosing a memory type, Vol.3-11-8
flushing TLBs, Vol.3-11-19
implicit caching, Vol.3-11-19
internal caches, Vol.3-11-1
L1 (level 1) cache, Vol.3-11-4
L2 (level 2) cache, Vol.3-11-4
L3 (level 3) cache, Vol.3-11-4
methods of caching available, Vol.3-11-6
MTRRs, description of, Vol.3-11-20
operating modes, Vol.3-11-12
overview of, Vol.3-11-1
self-modifying code, effect on, Vol.3-11-18, Vol.3-22-29
snooping, Vol.3-11-6
store buffer, Vol.3-11-20
TLBs, Vol.3-11-5
UC (strong uncacheable) memory type, Vol.3-11-6
UC- (uncacheable) memory type, Vol.3-11-6
WB (write back) memory type, Vol.3-11-7
WC (write combining) memory type, Vol.3-11-7
WP (write protected) memory type, Vol.3-11-7
write-back caching, Vol.3-11-6
WT (write through) memory type, Vol.3-11-7
Call gate, Vol.1-6-6
Call gates
16-bit, interlevel return from, Vol.3-22-32
accessing a code segment through, Vol.3-5-15
description of, Vol.3-5-13
for 16-bit and 32-bit code modules, Vol.3-21-1
IA-32e mode, Vol.3-5-14
introduction to, Vol.3-2-4
mechanism, Vol.3-5-15
privilege level checking rules, Vol.3-5-16
CALL instruction, Vol.1-3-17, Vol.1-6-3, Vol.1-6-4, Vol.1-6-7, Vol.1-7-15, Vol.1-7-22, Vol.2-3-99, Vol.3-2-5, Vol.3-3-9, Vol.3-5-10, Vol.3-5-15, Vol.3-5-20, Vol.3-7-2, Vol.3-7-9, Vol.3-7-10, Vol.3-21-5
Caller access privileges, checking, Vol.3-5-26
Calls
16 and 32-bit code segments, Vol.3-21-3
controlling operand-size attribute, Vol.3-21-5
returning from, Vol.3-5-20
Calls (see Procedure calls)
Canonical address, Vol.1-3-9
GETSEC, Vol.2-5-2
Capability MSRs
See VMX capability MSRs
Catastrophic shutdown detector
Thermal monitoring
catastrophic shutdown detector, Vol.3-14-21
catastrophic shutdown detector, Vol.3-14-20
CBW instruction, Vol.1-7-7, Vol.2-3-112
CC0 and CC1 (counter control) fields, CESR MSR (Pentium processor), Vol.3-18-96
CD (cache disable) flag, CR0 control register, Vol.3-2-14, Vol.3-9-7, Vol.3-11-10, Vol.3-11-12, Vol.3-11-13, Vol.3-11-16, Vol.3-11-32, Vol.3-22-17, Vol.3-22-18, Vol.3-22-29
CDQ instruction, Vol.1-7-7, Vol.2-3-231
CDQE instruction, Vol.2-3-112
Celeron processor
description of, Vol.1-2-3
CESR (control and event select) MSR (Pentium processor), Vol.3-18-95, Vol.3-18-96
CF (carry) flag, EFLAGS register, Vol.1-3-15, Vol.1-A-1, Vol.2-3-29, Vol.2-3-89, Vol.2-3-91, Vol.2-3-93, Vol.2-3-95, Vol.2-3-114, Vol.2-3-121, Vol.2-3-236, Vol.2-3-394, Vol.2-3-400, Vol.2-3-593, Vol.2-4-282, Vol.2-4-346, Vol.2-4-358, Vol.2-4-361, Vol.2-4-395
CH register, Vol.1-3-11
CL register, Vol.1-3-11
CLC instruction, Vol.1-3-15, Vol.1-7-21, Vol.2-3-114
CLD instruction, Vol.1-3-16, Vol.1-7-21, Vol.2-3-115
CLFLSH feature flag, CPUID instruction, Vol.3-9-8
CLFLUSH instruction, Vol.1-11-12, Vol.2-3-116, Vol.3-2-15, Vol.3-8-6, Vol.3-9-8, Vol.3-11-17
CPUID flag, Vol.2-3-177
CLI instruction, Vol.1-16-3, Vol.2-3-118, Vol.3-6-7
Clocks
counting processor clocks, Vol.3-18-80
Hyper-Threading Technology, Vol.3-18-80
nominal CPI, Vol.3-18-80
non-halted clockticks, Vol.3-18-80
non-halted CPI, Vol.3-18-80
non-sleep Clockticks, Vol.3-18-80
time stamp counter, Vol.3-18-80
CLTS instruction, Vol.2-3-120, Vol.3-2-21, Vol.3-5-24, Vol.3-25-2, Vol.3-25-6
Cluster model, local APIC, Vol.3-10-24

CMC instruction, Vol.1-3-15, Vol.1-7-21, Vol.2-3-121
CMOVcc flag, Vol.2-3-177
CMOVcc instructions, Vol.1-7-3, Vol.1-7-4, Vol.2-3-122, Vol.3-22-4
  CPUID flag, Vol.2-3-177
CMP instruction, Vol.1-7-8, Vol.2-3-126
CMPPD instruction, Vol.1-11-7, Vol.2-3-128
CMPPS instruction, Vol.1-10-9, Vol.2-3-135
CMPS instruction, Vol.1-3-16, Vol.1-7-18, Vol.2-3-141, Vol.2-4-306
CMPSB instruction, Vol.2-3-141
CMPSD instruction, Vol.1-11-7, Vol.2-3-141, Vol.2-3-145
CMPSQ instruction, Vol.2-3-141
CMPSS instruction, Vol.1-10-9, Vol.2-3-149
CMPSW instruction, Vol.2-3-141
CMPXCHG instruction, Vol.1-7-4, Vol.2-3-153, Vol.2-3-472, Vol.3-8-3, Vol.3-22-4
CMPXCHG16B instruction, Vol.1-7-5, Vol.2-3-155
  CPUID bit, Vol.2-3-175
CMPXCHG8B instruction, Vol.1-7-4, Vol.2-3-155, Vol.3-8-3, Vol.3-22-4
  CPUID flag, Vol.2-3-177
Code modules
  16 bit vs. 32 bit, Vol.3-21-1
  mixing 16-bit and 32-bit code, Vol.3-21-1
  sharing data, mixed-size code segs, Vol.3-21-3
  transferring control, mixed-size code segs, Vol.3-21-3
Code segment, Vol.1-3-13
Code segments
  accessing data in, Vol.3-5-9
  accessing through a call gate, Vol.3-5-15
  description of, Vol.3-3-12
  descriptor format, Vol.3-5-2
  descriptor layout, Vol.3-5-2
  direct calls or jumps to, Vol.3-5-10
  paging of, Vol.3-2-6
  pointer size, Vol.3-21-4
  privilege level checks
    transferring control between code segs, Vol.3-5-10
COMISD instruction, Vol.1-11-7, Vol.2-3-158
COMISS instruction, Vol.1-10-9, Vol.2-3-160
Compare
  compare and exchange, Vol.1-7-4
  integers, Vol.1-7-8
  real numbers, x87 FPU, Vol.1-8-19
  strings, Vol.1-7-18
Compatibility
  IA-32 architecture, Vol.3-22-1
  software, Vol.3-1-6
Compatibility mode

## I

IA-32 architecture
history of, Vol.1-2-1
introduction to, Vol.1-2-1
IA-32 Intel architecture
compatibility, Vol.3-22-1
processors, Vol.3-22-1
IA32e mode
registers and mode changes, Vol.3-9-12
IA-32e mode
call gates, Vol.3-5-14
code segment descriptor, Vol.3-5-3
CPUID flag, Vol.2-3-170
D flag, Vol.3-5-4
data structures and initialization, Vol.3-9-11
debug registers, Vol.3-2-7
debug store area, Vol.3-17-18
descriptors, Vol.3-2-4
DPL field, Vol.3-5-4
exceptions during initialization, Vol.3-9-11
feature-enable register, Vol.3-2-7
gates, Vol.3-2-4
global and local descriptor tables, Vol.3-2-4
IA32_EFER MSR, Vol.3-2-7, Vol.3-5-30
initialization process, Vol.3-9-10
interrupt stack table, Vol.3-6-19
interrupts and exceptions, Vol.3-2-5
introduction, Vol.1-2-21, Vol.2-2-7, Vol.2-2-13
IRET instruction, Vol.3-6-18
L flag, Vol.3-3-12, Vol.3-5-4
logical address, Vol.3-3-7
MOV CRn, Vol.3-9-10
MTRR calculations, Vol.3-11-27
NXE bit, Vol.3-5-30
page level protection, Vol.3-5-30
paging, Vol.3-2-6
PDE tables, Vol.3-5-31
PDP tables, Vol.3-5-31
PML4 tables, Vol.3-5-31
PTE tables, Vol.3-5-31
registers and data structures, Vol.3-2-1
see 64-bit mode
see compatibility mode
segment descriptor tables, Vol.3-3-16, Vol.3-5-3
segment descriptors, Vol.3-3-9
segment loading instructions, Vol.3-3-9
segmentation, Vol.1-3-21, Vol.3-3-5
stack switching, Vol.3-5-19, Vol.3-6-18
SYSCALL and SYSRET, Vol.3-5-22
SYSENTER and SYSEXIT, Vol.3-5-21
system descriptors, Vol.3-3-14
system registers, Vol.3-2-7
task switching, Vol.3-7-16
task-state segments, Vol.3-2-5
terminating mode operation, Vol.3-9-12
See also: 64-bit mode, compatibility mode
IA32_APERF MSR, Vol.3-14-2
IA32_APIC_BASE MSR, Vol.3-8-18, Vol.3-8-19, Vol.3-10-6, Vol.3-10-8, Vol.1-35-169
IA32_BIOS_SIGN_ID MSR, Vol.1-35-172
IA32_BIOS_UPDT_TRIG MSR, Vol.3-32-9, Vol.1-35-172
IA32_BISO_SIGN_ID MSR, Vol.3-32-9
IA32_CLOCK_MODULATION MSR, Vol.3-8-31, Vol.3-14-8, Vol.3-14-11, Vol.3-14-12, Vol.3-14-13, Vol.3-14-15, Vol.3-14-16, Vol.3-14-17, Vol.3-14-18, Vol.3-14-19, Vol.3-14-24, Vol.3-14-25, Vol.3-14-26, Vol.3-14-27, Vol.3-14-35, Vol.3-14-36, Vol.3-14-37, Vol.3-14-38, Vol.3-14-39, Vol.1-35-39, Vol.1-35-52, Vol.1-35-64, Vol.1-35-78, Vol.1-35-113, Vol.1-35-176, Vol.1-35-199, Vol.1-35-207
IA32_CTL MSR, Vol.1-35-173
IA32_DEBUGCTL MSR, Vol.3-27-24, Vol.1-35-180
IA32_DS_AREA MSR, Vol.3-17-16, Vol.3-17-19, Vol.3-17-20, Vol.3-18-59, Vol.3-18-75, Vol.1-35-190
IA32_EFER MSR, Vol.3-2-7, Vol.3-2-8, Vol.3-5-30, Vol.3-27-24, Vol.3-31-16
IA32_FEATURE_CONTROL MSR, Vol.3-23-3
IA32_KernelGSbase MSR, Vol.3-2-7
IA32_LSTAR MSR, Vol.3-2-7, Vol.3-5-22
IA32_MCG_CAP MSR, Vol.3-15-2, Vol.3-15-27, Vol.1-35-173
IA32_MCG_CTL MSR, Vol.3-15-2, Vol.3-15-4
IA32_MCG_EAX MSR, Vol.3-15-11
IA32_MCG_EBP MSR, Vol.3-15-11
IA32_MCG_EBX MSR, Vol.3-15-11
IA32_MCG_ECX MSR, Vol.3-15-11
IA32_MCG_EDI MSR, Vol.3-15-11
IA32_MCG_EDX MSR, Vol.3-15-11

Restarting program or task, following an exception or interrupt, Vol.3-6-5
Restricting addressable domain, Vol.3-5-28
RET instruction, Vol.1-3-17, Vol.1-6-3, Vol.1-6-4, Vol.1-7-15, Vol.1-7-22, Vol.2-4-309, Vol.3-5-10, Vol.3-5-20, Vol.3-21-6
Return instruction pointer, Vol.1-6-3
Returning
from a called procedure, Vol.3-5-20
from an interrupt or exception handler, Vol.3-6-13
Returns, from procedure calls
exception handler, return from, Vol.1-6-9
far return, Vol.1-6-4
inter-privilege level return, Vol.1-6-7
interrupt handler, return from, Vol.1-6-9
near return, Vol.1-6-4
REX prefixes, Vol.1-3-2, Vol.1-3-11, Vol.1-3-18
addressing modes, Vol.2-2-9
and INC/DEC, Vol.2-2-8
encodings, Vol.2-2-8, Vol.2-B-2
field names, Vol.2-2-9
ModR/M byte, Vol.2-2-8
overview, Vol.2-2-8
REX.B, Vol.2-2-8
REX.R, Vol.2-2-8
REX.W, Vol.2-2-8
special encodings, Vol.2-2-11
RF (resume) flag
EFLAGS register, Vol.3-2-10, Vol.3-6-7
RF (resume) flag, EFLAGS register, Vol.1-3-16, Vol.1-A-1
RFLAGS, Vol.1-3-17
RFLAGS register, Vol.1-7-22
See EFLAGS register
RIP register, Vol.1-6-4
64-bit mode, Vol.1-7-2
description of, Vol.1-3-17
relation to EIP, Vol.1-7-2
RIP-relative addressing, Vol.2-2-12
ROL instruction, Vol.1-7-13, Vol.2-4-280
ROR instruction, Vol.1-7-13, Vol.2-4-280
RORX - Rotate Right Logical Without Affecting Flags, Vol.2-4-319
Rounding
modes, floating-point operations, Vol.1-4-18, Vol.2-4-321
modes, x87 FPU, Vol.1-8-8
toward zero (truncation), Vol.1-4-18
Rounding control (RC) field
MXCSR register, Vol.1-4-18, Vol.1-10-4, Vol.2-4-321
x87 FPU control word, Vol.1-4-18, Vol.1-8-8, Vol.2-4-321
Rounding, round to integer, x87 FPU operation, Vol.2-3-324
RPL
description of, Vol.3-3-8, Vol.3-5-8
field, segment selector, Vol.3-5-2
RPL field, Vol.2-3-66
RSI register, Vol.1-3-11
RSM instruction, Vol.2-4-330, Vol.3-2-23, Vol.3-8-17, Vol.3-22-5, Vol.3-25-4, Vol.3-34-1, Vol.3-34-2, Vol.3-34-3, Vol.3-34-13, Vol.3-34-15, Vol.3-34-18
RSP register, Vol.1-3-11, Vol.1-6-4
RSQRTPS instruction, Vol.1-10-8, Vol.2-4-332
RSQRTSS instruction, Vol.1-10-8, Vol.2-4-334
RsvdZ, Vol.3-10-40
R/m field, instruction format, Vol.2-2-3
R/S# pin, Vol.3-6-3
R/W (read/write) flag
page-directory entry, Vol.3-5-1, Vol.3-5-2, Vol.3-5-28
page-table entry, Vol.3-5-1, Vol.3-5-2, Vol.3-5-28
R/W0-R/W3 (read/write) fields
DR7 register, Vol.3-17-4, Vol.3-22-19

## S

S (descriptor type) flag
segment descriptor, Vol.3-3-11, Vol.3-3-12, Vol.3-5-2, Vol.3-5-5
Safer Mode Extensions, Vol.2-5-1
SAHF instruction, Vol.1-3-14, Vol.1-7-21, Vol.2-4-336
SAL instruction, Vol.1-7-10, Vol.2-4-338
SAR instruction, Vol.1-7-11, Vol.2-4-338
Saturation arithmetic (MMX instructions), Vol.1-9-4
SBB instruction, Vol.1-7-8, Vol.2-3-472, Vol.2-4-345, Vol.3-8-3
Scalar operations
defined, Vol.1-10-7, Vol.1-11-5
scalar double-precision FP operands, Vol.1-11-5
scalar single-precision FP operands, Vol.1-10-7
Scale (operand addressing), Vol.1-3-21, Vol.1-3-22, Vol.1-3-23, Vol.2-2-3
Scale, x87 FPU operation, Vol.1-8-21, Vol.2-3-330
Scaling bias value, Vol.1-8-28, Vol.1-8-29
Scan string instructions, Vol.2-4-348
SCAS instruction, Vol.1-3-16, Vol.1-7-18, Vol.2-4-306, Vol.2-4-348
SCASB instruction, Vol.2-4-348
SCASD instruction, Vol.2-4-348
SCASW instruction, Vol.2-4-348
Segment
defined, Vol.1-3-6
descriptor, segment limit, Vol.2-3-479
limit, Vol.2-3-479
maximum number, Vol.1-3-6
registers, moving values to and from, Vol.2-3-510
selector, RPL field, Vol.2-3-66
Segment descriptors
access rights, Vol.3-5-24
access rights, invalid values, Vol.3-22-18
automatic bus locking while updating, Vol.3-8-3
base address fields, Vol.3-3-10
code type, Vol.3-5-2
data type, Vol.3-5-2
description of, Vol.3-2-4, Vol.3-3-9
DPL (descriptor privilege level) field, Vol.3-3-11, Vol.3-5-2
D/B (default operation size/default stack pointer size and/or upper bound) flag, Vol.3-3-11, Vol.3-5-4
E (expansion direction) flag, Vol.3-5-2, Vol.3-5-4
G (granularity) flag, Vol.3-3-11, Vol.3-5-2, Vol.3-5-4
limit field, Vol.3-5-2, Vol.3-5-4
loading, Vol.3-22-19
P (segment-present) flag, Vol.3-3-11
S (descriptor type) flag, Vol.3-3-11, Vol.3-3-12, Vol.3-5-2, Vol.3-5-5
segment limit field, Vol.3-3-10
system type, Vol.3-5-2
tables, Vol.3-3-14
TSS descriptor, Vol.3-7-5, Vol.3-7-6
type field, Vol.3-3-10, Vol.3-3-12, Vol.3-5-2, Vol.3-5-5
type field, encoding, Vol.3-3-14
when P (segment-present) flag is clear, Vol.3-3-11
Segment limit
checking, Vol.3-2-21
field, segment descriptor, Vol.3-3-10
Segment not present exception (#NP), Vol.3-3-11

Segment override prefixes, Vol.1-3-20
Segment registers
  64-bit mode, Vol.1-3-14, Vol.1-3-21, Vol.1-7-2
  default usage rules, Vol.1-3-20
  description of, Vol.1-3-10, Vol.1-3-12, Vol.3-3-8
  IA-32e mode, Vol.3-3-9
  part of basic programming environment, Vol.1-7-1
  saved in TSS, Vol.3-7-4
Segment selector
  description of, Vol.1-3-6, Vol.1-3-12
  segment override prefixes, Vol.1-3-20
  specifying, Vol.1-3-20
Segment selectors
  description of, Vol.3-3-7
  index field, Vol.3-3-7
  null, Vol.3-5-6
  null in 64-bit mode, Vol.3-5-6
  RPL field, Vol.3-3-8, Vol.3-5-2
  TI (table indicator) flag, Vol.3-3-7
Segmented addressing, Vol.2-1-5, Vol.3-1-7
Segmented memory model, Vol.1-1-6, Vol.1-3-6, Vol.1-3-12
Segment-not-present exception (#NP), Vol.3-6-34
Segments
  64-bit mode, Vol.3-3-5
  basic flat model, Vol.3-3-3
  code type, Vol.3-3-12
  combining segment, page-level protection, Vol.3-5-29
  combining with paging, Vol.3-3-5
  compatibility mode, Vol.3-3-5
  data type, Vol.3-3-12
  defined, Vol.3-3-1
  disabling protection of, Vol.3-5-1
  enabling protection of, Vol.3-5-1
  mapping to pages, Vol.3-4-46
  multisegment usage model, Vol.3-3-4
  protected flat model, Vol.3-3-3
  segment-level protection, Vol.3-5-2, Vol.3-5-3
  segment-not-present exception, Vol.3-6-34
  system, Vol.3-2-4
  types, checking access rights, Vol.3-5-24
  typing, Vol.3-5-5
  using, Vol.3-3-2
  wraparound, Vol.3-22-33
SELF IPI register, Vol.3-10-38
Self Snoop, Vol.2-3-178
Self-modifying code, effect on caches, Vol.3-11-18
GETSEC, Vol.2-5-2, Vol.2-5-3, Vol.2-5-5
SENTER sleep state, Vol.2-5-9
Serialization of I/O instructions, Vol.1-16-5
Serializing, Vol.3-8-16
Serializing instructions, Vol.1-16-5
  CPUID, Vol.3-8-16
  HT technology, Vol.3-8-29
  non-privileged, Vol.3-8-16
  privileged, Vol.3-8-16
SETcc instructions, Vol.1-3-16, Vol.1-7-14, Vol.2-4-352
GETSEC, Vol.2-5-4
SF (sign) flag, EFLAGS register, Vol.1-3-15, Vol.1-A-1, Vol.2-3-29
SF (stack fault) flag, x87 FPU status word, Vol.1-8-6, Vol.1-8-26, Vol.3-22-8
SFENCE instruction, Vol.1-10-14, Vol.1-11-12, Vol.1-11-25, Vol.2-4-355, Vol.3-2-15, Vol.3-8-6, Vol.3-8-15, Vol.3-8-16, Vol.3-8-17
SGDT instruction, Vol.2-4-356, Vol.3-2-21, Vol.3-3-15
SHAF instruction, Vol.2-4-336
Shared resources
  mapping of, Vol.3-8-33
Shift instructions, Vol.2-4-338
SHL instruction, Vol.1-7-10, Vol.2-4-338
SHLD instruction, Vol.1-7-12, Vol.2-4-358
SHR instruction, Vol.1-7-11, Vol.2-4-338
SHRD instruction, Vol.1-7-12, Vol.2-4-361
Shuffle instructions
  SSE extensions, Vol.1-10-9
  SSE2 extensions, Vol.1-11-7
SHUFPD instruction, Vol.1-11-7, Vol.2-4-364
SHUFPS instruction, Vol.2-4-367
Shutdown
  resulting from double fault, Vol.3-6-29
  resulting from out of IDT limit condition, Vol.3-6-29
SI register, Vol.1-3-11
SIB byte, Vol.2-2-3
  32-bit addressing forms of, Vol.2-2-7, Vol.2-2-20
  description of, Vol.2-2-3
SIDT instruction, Vol.2-4-356, Vol.2-4-370, Vol.3-2-21, Vol.3-3-16, Vol.3-6-9
Signaling NaN (see SNaN)
Signed
  infinity, Vol.1-4-15
  integers, description of, Vol.1-4-4
  integers, encodings, Vol.1-4-4
  zero, Vol.1-4-14
Significand, extracting from floating-point number, Vol.2-3-371
Significand, of floating-point number, Vol.1-4-11
Sign, floating-point number, Vol.1-4-11
SIMD floating-point exception (#XM), Vol.1-11-18, Vol.3-2-18, Vol.3-6-48, Vol.3-9-8
SIMD floating-point exceptions
  denormal operand exception (#D), Vol.1-11-15
  description of, Vol.3-6-48, Vol.3-13-5
  divide-by-zero (#Z), Vol.1-11-15
  exception conditions, Vol.1-11-14
  exception handlers, Vol.1-E-1
  handler, Vol.3-13-2
  inexact result exception (#P), Vol.1-11-16
  invalid operation exception (#I), Vol.1-11-14
  list of, Vol.1-11-13
  numeric overflow exception (#O), Vol.1-11-15
  numeric underflow exception (#U), Vol.1-11-16
  precision exception (#P), Vol.1-11-16
  software handling, Vol.1-11-18
  summary of, Vol.1-C-1
  support for, Vol.3-2-18
  writing exception handlers for, Vol.1-E-1
SIMD floating-point exceptions, unmasking, effects of, Vol.2-3-454, Vol.2-4-289, Vol.2-4-557
SIMD floating-point flag bits, Vol.1-10-4
SIMD floating-point mask bits, Vol.1-10-4
SIMD floating-point rounding control field, Vol.1-10-4
SIMD (single-instruction, multiple-data)
  execution model, Vol.1-2-2, Vol.1-2-3, Vol.1-9-4
  instructions, Vol.1-2-15, Vol.1-5-16, Vol.1-10-7
  MMX instructions, Vol.1-5-12

I/O map base address field, Vol.3-7-5, Vol.3-22-28
I/O permission bit map, Vol.1-16-4, Vol.3-7-5, Vol.3-7-17
LDT segment selector field, Vol.3-7-4, Vol.3-7-14
link field, Vol.3-6-14
order of reads/writes to, Vol.3-22-28
pointed to by task-gate descriptor, Vol.3-7-8
previous task link field, Vol.3-7-4, Vol.3-7-12, Vol.3-7-13
privilege-level 0, 1, and 2 stacks, Vol.3-5-17
referenced by task gate, Vol.3-6-14
saving state of EFLAGS register, Vol.1-3-14
segment registers, Vol.3-7-4
T (debug trap) flag, Vol.3-7-5
task register, Vol.3-7-7
using 16-bit TSSs in a 32-bit environment, Vol.3-22-28
virtual-mode extensions, Vol.3-22-28
TSS descriptor
B (busy) flag, Vol.3-7-5
busy flag, Vol.3-7-13
initialization for multitasking, Vol.3-9-10
structure of, Vol.3-7-5, Vol.3-7-6
TSS segment selector
field, task-gate descriptor, Vol.3-7-8
writes, Vol.3-22-28
TSS, relationship to task register, Vol.2-4-392
Type

checking, Vol.3-5-5
field, IA32_MTRR_DEF_TYPE MSR, Vol.3-11-22
field, IA32_MTRR_PHYSBASEn MTRR, Vol.3-11-24, Vol.3-11-26
field, segment descriptor, Vol.3-3-10, Vol.3-3-12, Vol.3-3-14, Vol.3-5-2, Vol.3-5-5
of segment, Vol.3-5-5
TZCNT - Count the Number of Trailing Zero Bits, Vol.2-4-417

## U

UC- (uncacheable) memory type, Vol.3-11-6
UCOMISD instruction, Vol.1-11-7, Vol.2-4-417
UCOMISS instruction, Vol.1-10-9, Vol.2-4-421
UD2 instruction, Vol.1-7-24, Vol.2-4-423, Vol.3-22-4
UE (numeric underflow exception) flag
MXCSR register, Vol.1-11-16
x87 FPU status word, Vol.1-8-5, Vol.1-8-29
UM (numeric underflow exception) mask bit
MXCSR register, Vol.1-11-16
x87 FPU control word, Vol.1-8-7, Vol.1-8-29
Uncached (UC-) memory type, Vol.3-11-8
Uncached (UC) memory type (see Strong uncached (UC) memory type)
Undefined opcodes, Vol.3-22-5
Undefined, format opcodes, Vol.2-3-352
Underflow
FPU exception
(see Numeric underflow exception)
numeric, floating-point, Vol.1-4-14
x87 FPU stack, Vol.1-8-25
Underflow, x87 FPU stack, Vol.1-8-25
Unit mask field, PerfEvtSel0 and PerfEvtSel1 MSRs (P6 family processors) , Vol.3-18-3, Vol.3-18-5, Vol.3-18-6, Vol.3-18-7, Vol.3-18-8, Vol.3-18-9, Vol.3-18-14, Vol.3-18-15, Vol.3-18-30, Vol.3-18-32, Vol.3-18-39, Vol.3-18-40, Vol.3-18-41, Vol.3-18-57, Vol.3-18-93
Un-normal number, Vol.3-22-9
Unordered values, Vol.2-3-276, Vol.2-3-352, Vol.2-3-354
Unpack instructions
SSE extensions, Vol.1-10-9
SSE2 extensions, Vol.1-11-7
UNPCKHPD instruction, Vol.1-11-8, Vol.2-4-424
UNPCKHPS instruction, Vol.1-10-10, Vol.2-4-426
UNPCKLPD instruction, Vol.1-11-8, Vol.2-4-428
UNPCKLPS instruction, Vol.1-10-10, Vol.2-4-430
Unsigned integers
description of, Vol.1-4-3
range of, Vol.1-4-3
types, Vol.1-4-3
Unsupported, Vol.1-8-14
floating-point formats, x87 FPU, Vol.1-8-14
x87 FPU instructions, Vol.1-8-23
User mode
description of, Vol.3-5-28
U/S (user/supervisor) flag, Vol.3-5-28
User-defined interrupts, Vol.3-6-1, Vol.3-6-51
USR (user mode) flag, PerfEvtSel0 and PerfEvtSel1 MSRs (P6 family processors), Vol.3-18-3, Vol.3-18-5, Vol.3-18-6, Vol.3-18-7, Vol.3-18-8, Vol.3-18-9, Vol.3-18-14, Vol.3-18-15, Vol.3-18-30, Vol.3-18-32, Vol.3-18-39, Vol.3-18-40, Vol.3-18-41, Vol.3-18-57, Vol.3-18-93
U/S (user/supervisor) flag
page-directory entry, Vol.3-5-1, Vol.3-5-2, Vol.3-5-28
page-table entries, Vol.3-20-8
page-table entry, Vol.3-5-1, Vol.3-5-2, Vol.3-5-28

## V

V (valid) flag
IA32_MTRR_PHYSMASKn MTRR, Vol.3-11-24, Vol.3-11-26
